Cellulose ethers. HELENE SESSLER (to C. F. Boehringer & Soehne, G. m. b. H.). U. S. 1,704,304, March 5. Cellulose, which may be in the form of mercerized cotton, is subjected to the action of a vapor stream of an ether-forming reagent such as Me_2SO , in the presence of a mercerizing reagent or other suitable basic substance.

Cellulose esters. HERBERT J. MALLABAR. Fr. 645,110, Dec. 3, 1927. A blue-violet dye such as methylviolet extra B is added to cellulose esters in proportion sufficient to neutralize the natural yellow thereof. The same effect may be obtained by applying to one face of a film a prepn. contg. a red dye and to the other face a prepn. contg. a blue dye.

Cellulose esters. I. G. FARBENIND. A.-G. Fr. 644,636, Nov. 26, 1927. Cellulose esters of higher fatty acids are made sol. in org. solvents by heating them in a liquid medium to a high temp. with acids, acid anhydrides, or salts of strong acids with feeble bases or mixts. of these. In examples, cellulose tristearate in tetrachloroethane is heated to 145° with the addn. of trichloroacetic acid or in toluene with FeCl_3 to 90 – 100° . The product is sol. in C_6H_6 , CHCl_3 and tetrachloroethane. Cellulose trilaurate is heated in tetrachloroethane with the addn. of the HCl compd. of pyridine. Cellulose dipalmitate is heated in C_6H_6 with the addn. of AlCl_3 , ZnCl_2 , or a salt of H_2SO_4 or of benzenesulfonic acid. Cf. C. A. 23, 1749.

Soluble cellulose esters containing phthalic groups. RAY L. STINCHFIELD (to Eastman Kodak Co.). U. S. 1,704,306, March 5. An ester sol. in org. solvents such as acetone, CHCl_3 and C_6H_6 , and suitable for films, filaments, etc., comprises phthalic and cellulosic groups and may be formed by a process, the details of which are described.

Mixed organic esters of cellulose. HANS T. CLARKE and CARL J. MALM (to Eastman Kodak Co.). U. S. 1,704,282, March 5. Mixed esters sol. in acetone and in C_6H_6 and which are suitable for making films and filaments contain, for every 24 C atoms of the cellulose mol., less than 4 (but more than one-third of one) acyl groups from the higher aliphatic acids such as lauric, myristic, palmitic and stearic acids having more than 8 C atoms, the remaining acyls being acetyl groups. U. S. 1,704,283 specifies halogen-substituted-cellulosic org. acid esters, such as those of *o*-chlorobenzoic acid contg. 1-3 acid groups for each 6 C atoms of the cellulosic group, which are sol. in a neutral volatile solvent such as CHCl_3 and acetone, and suitable for films, etc.

Cellulose acetate. G. W. MORDEN. Brit. 294,415, Nov. 25, 1927. Cellulose is treated with sulfuryl chloride, glacial HOAc and Ac_2O ; the acetylation is subsequently finished in a second stage by treatment with Ac_2O , glacial HOAc and H_2SO_4 . The cellulose acetate formed is hydrolyzed to render it easily sol. in acetone; it is suitable for making films.

Molding compositions containing cellulose acetate. G. TRÜMLER. Brit. 294,251, July 21, 1927. Cellulose acetate (which may be mixed with resins and softening agents) is made into a paste, suspension, or soln. with a volatile liquid such as spirit; the product is heated in boiling water, in salt soln., or by superheated steam to drive off the volatile liquid and to leave a brittle loose mass, which is dried and pulverized; it can then be formed by hot molding or extrusion. Fillers, coloring agents, etc., also may be added.

Covering articles with celluloid. J. M. HALBY. Brit. 294,969, Nov. 16, 1927. A strip or sheet of celluloid is rendered pliable by treatment with a softening medium such as a mixt. of acetone and water or of acetone, "methylated spirit" and benzene,

in this condition it is applied to automobile steering wheels or to other articles to be covered, and is stretched into place, allowed to dry, and then polished.

Nitrocellulose coating composition. HAMILTON BRADSHAW, EDGAR H. NOLLAU and RICHARD G. WOODBRIDGE (to E. I. Du Pont de Nemours & Co.). U. S. 1,703,415, Feb. 26. A nitrocellulose of over 12.4% N content is colloided (suitably by use of denatured alc.); the colloided material is comminuted, seasoned for about 2-4 weeks at a temp. of about 60°, further seasoned at atm. temp. until a standard testing soln. made from it shows a viscosity of less than 200 sec. (when measured by a method which is described) and then dissolved in a solvent such as alc., C_6H_6 and EtOAc. The soln. thus formed is suitable for *coating fabrics*. Di-Bu phthalate, castor oil and pigments may be added.

Sulfuric derivatives of carbohydrates. W. TRAUBE. Brit. 294,572, July 26, 1927. Products adapted for use as protective colloids or as intermediates in the manuf. of cellulose acetates and nitrates are made by treating dry cellulose with SO_3 ; wood, straw, and other carbohydrates such as starch may be similarly treated. Either gaseous SO_3 or fuming sulfuric acid may be used and various details and modifications are described.

Viscose. WERNER CHATELAIN. Fr. 645,790, Dec. 16, 1927. A construction of a distributor of viscose to the pistons in the manuf. of artificial silk is described.

Viscose distributors in artificial-silk manufacture. EMILE-HIPPOLYTE-JÉRÔME REBSOMEN. Fr. 33,218, Mar. 23, 1927. Addn. to 596,314. Constructional details

Artificial silk and films from viscose. COURTAULDS, LTD., and J. H. TAYLOR. Brit. 294,805, Oct. 10, 1927. Liquid petroleum material of high b. p. or petroleum jelly added to viscose to reduce the luster of threads, films or the like formed from it is emulsified with the viscose by the use of cyclohexanol, with or without the addn. of other substances such as oleic acid.

Artificial silk. CAMILLE DREYFUS. Fr. 644,985, Dec. 1, 1927. Delustering of material consisting of or contg. cellulose acetate, etc., is prevented by adding to a bath in which delustering might occur a salt of the formula $RCNS$, in which R is NH_4 , an alkali or alk. earth metal. Thus, between 1 and 10% of $Ca(CNS)_2$ may be used.

Artificial silk. NAAMLOOZE VENNOOTSCHAP NEDERLANDSCHE KUNSTZIJDEFABRIEK. Fr. 644,673, Nov. 28, 1927. Artificial threads of greater solidity are obtained by passing them for a distance of at least 50 cm. under the surface of the spinning bath before a long path in the air.

Artificial silk. SOCIÉTÉ CHIMIQUE DES USINES DU RHONE. Brit. 294,623, July 29, 1927. See Fr. 638,448 (C. A. 23, 278).

Pump for artificial-silk manufacture. FA. ALEX. FRIEDMANN. Austrian 112,240, May 15, 1928.

Pump for artificial-silk manufacture. HENRY DREYFUS. Fr. 644,597, Oct. 26, 1927. A pump for the delivery of spinning solus. to the spinning nozzles is described.

Wood-pulp digestion. EINAR MORTERUD. U. S. 1,703,745, Feb. 26. In order to reduce the pressure in a digester immediately before discharging, at the termination of the digesting process, the digesting liquid is conducted from the digester to a sep. gas- and steam-liberating vessel, which is under a reduced pressure; the liquid is then returned to the digester after sepn. of steam and gas. An app. is described.

Apparatus for forming sheets of fibrous pulp. JESSE B. HAWLEY (to Arvey Mfg Co.). U. S. 1,704,706, March 12.

Dewatering paper pulp and the like by pressing. RICHARD KASTNER and HERBERT SCHMOLKA. Austrian 112,259, Oct. 15, 1928. The operation is conducted at a temp. of about 60°.

Paper-making apparatus. LELAND S. ROSENER and DAVID H. PATTERSON, JR. (to The Paraffine Companies). U. S. 1,704,216, March 5.

Paper manufacture. JUDSON A. DECEW. U. S. 1,704,728, March 12. Gases are removed from the solid and liquid materials constituting paper stock (suitably by a vacuum pump) before the stock is converted into paper. An arrangement of an app. is described.

Reworking used paper. JOSEPH O. PEIRCE and WARREN T. REDDISH (to Twitchell Process Co.). U. S. 1,703,830, Feb. 26. Used paper is repulped, foreign matter is sepd. by use of a mineral-oil sulfonic reagent, the pulp is washed and then used for making new paper.

Paper having a glossy surface of regenerated cellulose. ALBRECHT SCHMIDT, GERHARD BALLE and KUNO FRANZ (to I. G. Farbenind. A.-G.). U. S. 1,703,961, March 5. A film of regenerated cellulose is united with a paper web during manuf.

Paper (suitable for cigaret mouthpieces). WICKEL & Co., KOMMANDIT-GES. Brit. 294,492, July 23, 1927. Paper such as thin tissue paper is treated with a water-insol. material such as a natural or synthetic resin or cellulose deriv., which may serve as a carrier for a metal-reflective iridescent face.

Transparent wrapping material. F. K. WICKEL. Brit. 294,463, July 23, 1927. Material such as thin sheets of cellulose derivs. or paper rendered transparent by the use of resin is treated with a mirror-forming substance, e. g., rubbed with BiOCl. The mirror effect may be preserved and interference effects produced by coating with a dil. soln. of resin.

Metal-coated paper. H. GLOOTZ. Brit. 294,154, July 18, 1927. Mech. features of manuf.

Cardboard. G. E. HEYL and HYCOLITE LIQUID WALLPAPER MFG. CO., LTD. Brit. 294,442, Jan. 26, 1928. Paper such as waste paper or fibrous pulp is finely subdivided in a dry condition by a high-speed disintegrator; it is then mixed into a stiff paste or dough with water and a binder such as dextrin or resin glue, treated in a colloid mill, and then formed into sheets by passing between rolls and dried.

Storing half-stuff, whole stuff, or the like. RICHARD AIGNER. Austrian 112,270, Oct. 15, 1928. The half-stuff, etc., on leaving the rollers of a dewatering machine is craped and piled up while still damp.

24—EXPLOSIVES AND EXPLOSIONS

CHARLES E. MUNROE

Value of the methyl violet, zinc iodide-starch and Abel tests in comparison with other methods for determining the stability of smokeless powder. F. LENZE AND L. MERTZ. Chem.-Tech. Reichsanstalt, Berlin. *Z. ges. Schiess-Sprengstoffw.* 23, 340-3, 381-4, 428-31 (1928).—Nine samples of smokeless powders made with and without stabilizers, widely varying in age and in stability, were tested by various stability tests, including the methyl violet test at 134.5°, ZnI-starch test at 80°, Abel test at 76.7°, German test at 132°, storage tests at 100° and 75°, Bergmann-Junk test at 132°, and Hansen's H-ion test at 110°. Conclusion: The methyl violet, ZnI, and Abel tests do not give reliable indications of actual stability. They indicate only the first traces of decompn. and are influenced by various factors, such as light and weather conditions. The Bergmann-Junk test is regarded as giving the most reliable measure of stability. The storage tests give good agreement with the Bergmann-Junk test, although the time required for the 75° test excludes it as a practical factory test. A further study of the H-ion method is to be undertaken. C. G. S.

The velocity of ignition of inflammable substances in air. HEINRICH MACHE. *Sitzb. Akad. Wiss. Wien., Abt. IIa*, 137, No. 7, 455-62 (1928).—Expts. were made on the velocity of ignition over a liquid surface. The temp. of liquid surface was detd. by a Pt thermometer. Atm. pressure and moisture were recorded. The velocity of ignition is given for toluene (15.8-26.9°), alc. 99% (8.7-30.3°), alc.-water mixt. at 18.5° a benzene-CCl₄ mixt. at 10.8°, for benzene (3.5-28.5°), benzene (6.2-25.8°), ether (3.3-18.9°), acetone (4.2-25.5°), pentane (2.9-16.6°). FRANK URBAN

Colored light compositions. H. HENKEL. *Z. ges. Schiess-Sprengstoffw.* 23, 388-9 (1928).—Formulas are given for various compns. suitable for producing flame of various colors in *pyrotechnics*. The functions of the different ingredients are discussed and equations of combustion given. S used must be powd. brimstone, not "flowers" of S, because of traces of H₂SO₄ in the latter. Compns. contg. Mg or Al must be thoroughly dried and not stored in a warm place, in order to avoid oxidation. C. G. STORM

A safe apparatus for crimping blasting caps to fuse. ANON. *Z. ges. Schiess-Sprengstoffw.* 23, 378-80 (1928).—A description is given, with illustrations, of an app. for protecting workers from accidental explosion of blasting caps in the crimping operation and for producing a crimp that is watertight. C. G. STORM

A new testing station. ANON. *Z. ges. Schiess-Sprengstoffw.* 23, 427-8 (1928).—A brief description is given of a new exptl. testing gallery at Freiberg for detg. the safety of coal mining explosives. C. G. STORM

Highlights in electrifying a powder mill. FRED A. L. SCHMIDT. *Chem. Met. Eng.* 36, 79-81 (1929).—Installation details due to special hazards are given. E. M. S.

Tungsten alloy [for ammunition] (U. S. pat. 1,703,577) 9.

Explosives. ADOLPHE SEGAY. Fr. 645,566, Dec. 12, 1927. Antifiredamp explosives contain (1) NH_4NO_3 59, NaCl 18, trinitronaphthalene 13, KCl 10% NH_4NO_3 60, NaCl 20, trinitronaphthalene 10, gelatinized nitroglycerin 10% NH_4NO_3 59, NaCl 20, trinitronaphthalene 8, trinitrotoluene 5, KClO_4 10%.

Storing explosive gases. SVENSKA AKTIEBOLAGET GASACCUMULATOR. Fr. 644,695, Nov. 29, 1927. Inorg. porous material such as pumice stone, clay or infusorial earth, used for storing explosive gases, is satd. with a soln. of one or more inorg. salts and dried. Suitable salts are ZnCl_2 , or NH_4 or B salts.

Storing gases. AUTOGEN GASACCUMULATOR A.-G. Ger. 470,794, Dec. 5, 1926. Inorg. granular porous fillings for use in storing explosive gases, e. g., C_2H_2 , are improved by depositing thereon finely divided inorg. substances, e. g., by treatment with solns. of CaCl_2 and Na_2SiO_3 or with solns. of Zn or Cu salts. Cf. C. A. 23, 708.

Trinitrotoluene. AKTIEN-GESELLSCHAFT LIGNOSE. Brit. 294,625, July 29, 1927. Fused dinitrotoluene at a temp. of $80-95^\circ$ is added to nitrating acid at 80° while stirring, and cooling if desired, and the reaction is regulated by regulating the rate of addn. of the dinitrotoluene.

Electrically ignited detonating or blasting cap. ALFONS G. SCHURICHT and JOSEPH D. McNUTT (to Western Cartridge Co.). U. S. 1,704,222, March 5. A priming or igniting charge which is used comprises a granular brisant material such as Hg fulminate crystals, the grains of which are coated with PbO or other suitable deterrent.

Blasting cartridge for use with liquid or solid carbon dioxide. HARRY S. HART. U. S. 1,705,248, March 12. An auxiliary explosive charge is mounted within the cartridge for raising the temp. of the CO_2 to above the crit. temp. and the cartridge is constructed so as to rupture transversely at a definite point in the wall of the casing and permit escape of gaseous CO_2 at a predetd. pressure.

Fuses for exploding bombs to be dropped into water. P. SCHWENKE. Brit. 294,077, Jan. 23, 1928. When the bomb is dropped into water, heat is generated by the action of the water on a substance such as CaC_2 or Na which in turn serves to burst a tube contg. an acid such as H_2SO_4 so that the latter can react with a charge of KClO_4 or the like and the latter action fires a charge of gunpowder in the bomb. Various structural features are described.

25—DYES AND TEXTILE CHEMISTRY

L. A. OLNEY

Emile Bronnert. ARNOLD H. HARD. *Silk J.* 5, No. 54, 69-70(1928).—Obituary. CHAS. E. MULLIN

To the memory of Moritz von Gallois. (August, 1859-December, 1928.) An obituary and a contribution to the history of the chemistry of azo dyes. ANON. *Z. angew. Chem.* 42, 169-70(1929). E. H.

Effects of after-treatments on the degree of aggregation, location, shade, and fastness properties of insoluble azo colors on the fiber. F. M. ROWE. *Chemistry and Industry* 48, 77-8(1929); cf. C. A. 20, 825.—R. discusses previous publications on this subject in connection with his own work. The effects (degree of aggregation and location, shade, fastness to light, rubbing and bleeding) of several after-treatments of graded severity in water, soap, Na_2CO_3 and NaOH solns. for various lengths of time and temps. were studied on various fibers (gray, bleached, mercerized and bleached cottons, rayon) dyed with 30 combinations of diazotized bases and members of the naphthol AS series. Microscopic comparison must be made only between fibers of similar structure. Hot after-treatments influence the state of aggregation and location of azoic colors in the fiber in varying degrees according to the nature of the dyed fiber, the constitution of the azo compd., and the depth of the shade. The presence of moisture is essential; a trace, however, is sufficient. The particles increase in size, but growth in the swollen cell cannot proceed indefinitely without rupturing the fiber. Consequently, the particles migrate to the free surface where growth can continue more readily. Severe treatments, which promote swelling of the fiber, facilitate migration. In solid fibers like viscose rayon migration is always outward, the center of the fiber becoming colorless. Aggregation continues at the outer surface from which the crystals are easily removed, finally leaving the fiber colorless. With hollow fibers, such as cotton, the dye particles migrate inward to the lumen and also outward to the cuticle, and eventually after severe after-treatment, the color is left only in the lumen. This led Kayser (cf. C. A. 20, 2249) erroneously to conclude that migration

of the pigment in cotton is wholly inward. Aggregation and migration occur more readily in viscose rayon than in cotton. Examns. of dyeings kept 20–40 yrs. showed that these processes proceed very slowly at normal temp. and humidity. Hot soap solns. (Na_2CO_3 , NaOH) produce an effect similar to but more rapid than that of water. Aggregation and migration of azoic colors in the fiber are accompanied by changes in hue and brightness of the dyed material, and by changes in fastness to light, rubbing and bleeding. The ease of aggregation and migration of the coloring material is a reliable guide in searching for azo combinations resistant to kier boiling. Fastness to light increases with increase in size of particles. FREDERICK C. HAHN

Chemical notes (2). Annatto. A. W. R. JOACHIM. Ceylon Dept. Agr. Peradeniya. *Trop. Agr.* (Ceylon) 71, 148–50(1928).—Some methods of obtaining the dye from annatto seeds were tested. The amt. of dye obtained by the usual method of fermenting was 5% of the wt. of the seed. By extg. fresh seed with Na_2CO_3 soln. 4% of dye was obtained. Other methods are briefly discussed. Five references are given. A. L. MEHRING

Theory of basic dyeing. S. M. LIPATOV, O. S. YAMENKOVA and H. V. LIPATOVA. *Melhand Textilber.* 10, 51–4(1929).—A survey of mill practice showed many inconsistencies and uneconomical mixts. for the best results. The max. fixation of basic dye occurs at pH 7. The addn. of HOAc is therefore undesirable. EtOH hinders dissoen. and retards dyeing. $\text{Zn}(\text{C}_2\text{H}_3\text{O}_2)_2$ is a desirable salt addn. E. R. CLARK

Waterproof dyeing. KRIJI ODA. *Mem. Coll. Eng. Kyushu Imp. Univ.* 5, 71–92 (1928).—A study is made of waterproof dyeing of silk, cotton and rayon with urushi acid (from Japan lack) (I), stearic (II), or palmitic (III), acid or gelatin (IV) in conjunction with mordants. The textile or fibers are immersed in an aq. emulsion (soln. in the case of IV) of one of the foregoing materials, and then treated with an Fe, Al, or Cr mordant. The emulsion is prepd. by adding an alc. soln. of the material to water. Detailed procedures are given for dyeing in this manner. This method of waterproof dyeing has the following advantages in dyeing viscose rayon: (1) gives gloss similar to that of real silk; (2) improves the feel; (3) increases water resistance; (4) increases dry and wet tenacity; (5) decreases inflammability to a minimum. The dry and wet tenacities of viscose rayon resulting from the treatments are, resp.: untreated, 365.7, 116.9 g.; treated with I, 396.2, 195.6; with II, 393.2, 204.6; with III, 395.8, 232.0; with IV, 421.9, 138.5. F. C. H.

Half century of the development of dyeing machinery. HARRY S. DRUM and L. P. KLOPP. *Textile Colorist*, 50th Anniversary (1879–1928), 49–53.—A review. RUBY K. WORNER

Materials used for sizing and finishing (textiles). MAURICE DE KEGHEL. *Tibe*

4, 517-23, 657-63, 933-7, 1199-1207, 1457-63(1926); 5, 161-9, 319-23(1927).—A review of the properties and uses in textile finishing of gum tragacanth and similar products, gummo-mucilaginous substances (hyacinth gum, carob-seed gum, bark gums), mosses, algae and lichens, and starches.

Use of zinc dust in discharge printing (textiles). LEO KOLLMANN. *Melliand Textilber.* 9, 1008-12(1928).—In the use of zinc dust for discharge styles attention must naturally be given to the effect on the ground color. Many dyes which discharge well with Rongalit are not suitable for use with zinc dust. The difference is particularly noticeable in the printing of wool and silk. In the use of zinc dust a browning of the white due to ZnS formation is not to be feared as it is when S compds. are used. Zn discharges are somewhat sensitive to steam carrying air. It is believed that Zn dust has a distinct field in hand printing.

E. R. CLARK

Thickeners for (textile) printing. R. HALLER. *Melliand Textilber.* 9, 586-90, 771-2, 850-2, 931-2, 997-1000(1928).—The effort was made to relate the fine structure of thickened dye solns., as seen in microscopic examn. of slides prepd. with EtOH, to practical working directions based on experience. Several photographs are reproduced. In most cases indication of ordered structure was found. None of these was of such a nature as to indicate the correctness of Bütschli's honeycomb arrangement of particles in dispersions of this type. It appears that a rather gross arrangement visible with 150x magnification, governs the behavior of these thickened dye solns.

RUBY K. WORNER

Microbiology of wool. R. BURGESS. *J. Textile Inst.* 19, 315-22T(1928).—The essential properties of an efficient antiseptic for the prevention of mildew in woollen goods are described. While many substances such as NaF, chloramine-T, chlorinated phenols, etc., do not inhibit the growth of fungi and bacilli, others such as HgCl₂, salicylic acid, Ti carbonate, etc., and notably Na fluosilicate, give better protection. The protective effect of dyes is discussed, and chrome dyeing is found to afford considerable protection. The conditions of testing antiseptics, the effect of the alk. or acidity of the cloth under examn., and methods of detecting damaged fibers by staining tests are discussed.

Dyes. BRITISH DYESTUFFS CORP., LTD., J. BADDILEY, P. CHORLEY and R. BRIGHTMAN. Brit. 294,922, April 28, 1927. Disazo dyes are formed by coupling tetrazotized 2-nitro- or 2,2'-dinitrobenzidine with 2 mol. proportions of a 2,8-aminonaphtholsulfonic acid or deriv., or with 1 mol. proportion of such an acid or deriv. and 1 mol. proportion of another coupling component. Numerous examples are given, some of which involve products suitable for use on regenerated cellulose "silk" and some suitable for use on wool.

Dyes. BRITISH DYESTUFFS CORPORATION, LIMITED. Fr. 644,737, Nov. 30, 1927. Vat dyes are made into a paste with dispersing and wetting agents and dried. As dispersing agents, the condensation product of HCOOH and naphthalenesulfonic acid, sulfite-cellulose resin, ligninsulfonic acid or the product obtained by treating this with HNO₃ or with alkalis or NH₃ may be used. Wetting agents include alkyl-naphthalenesulfonic acids and sulfonated oils.

Dyes. COMPAGNIE NATIONALE DE MATIÈRES COLORANTES ET MANUFACTURES DE PRODUITS CHIMIQUES DU NORD RÉUNIS ÉTABLISSEMENTS KUHLMANN. Brit. 295,050, Aug. 5, 1927. 4-Chloro-6-sulfobenzediazo oxide is made by the action of NaOAc on diazotized 2-nitro-4-chloro-6-sulfo-1-aminobenzene and may be coupled with azo components to form mordant dyes dyeing wool directly in an acid bath and producing very fast dyeings when after-chromed or coppered. Several examples are given.

Dyes. J. R. GRIGY A.-G. Brit. 295,032, Aug. 6, 1927. Strongly basic azo dyes are obtained by treating an unsulfonated aminoazo dye successively with chloroacetyl chloride and a tertiary or secondary aromatic base or a di- or tri-alkylamine of the aliphatic series, or by treating one or more of the components successively with the chloroacetyl chloride and the base and subsequently coupling to produce the dye. The products form sol. hydrochlorides and on tannin-mordanted cotton give dyeings fast to light, washing, acids and alkalis. Numerous examples are given.

Dyes. Soc. ANON POUR L'IND. CHIM. A BAIE. Brit. 294,481, July 21, 1927. Chlorinated violanthrones are made by chlorinating violanthrone with such a proportion of FeCl₃ that the product dyes cotton, from the vat, blue tints fast to water. The chlorinated product may also be used for printing, or may be converted to a leuco

deriv. or leuco-ester salt, and the latter employed for dyeing or printing. The treatment with FeCl_3 may be effected in trichlorobenzene at a temp. of $140-150^\circ$.

Dyes. SOC. ANON. POUR L'IND. CHIM. À BAËLE. Brit. 294,583, July 26, 1927. Azo dyes are obtained by coupling diazo, diazoazo or tetrazo compds. with the pyrazolones formed by the condensation of oxalacetic acid esters with hydrazine. Various of the products (a large number of examples of which are given) are suitable for use as acid dyes, *varnish colors*, direct cotton dyes, mordant dyes, or for combination with metals such as Cu or Cr.

Dyes. I. G. FARBENIND. A.-G. Brit. 294,291, April 26, 1927. Violet monoazo dyes are produced in substance or on the fiber by coupling diazotized aminonaphthol ethers with arylides of 2,3-hydroxynaphthoic acid; e. g., diazotized 7-methoxy-1-aminonaphthalene may be coupled with 2,3-hydroxynaphthoic- β -naphthylamine; which gives a product dyeing reddish violet fast to Cl and to light and boiling.

Dyes. I. G. FARBENIND. A.-G. Brit. 294,360, May 4, 1927. Condensation products of the benzanthrone series are made by using NH_3 instead of an amine or amide in processes such as those described in Brit. 249,891 (C. A. 21, 1016). Various details and examples are given.

Dyes. I. G. FARBENIND. A.-G. Brit. 294,550, July 25, 1927. 3,4,8,9-Dibenzopyrene-5,10-quinones are prepd. by condensation of α -benzoylnaphthalene or one of its derivs. having the 4, 5 and 8 positions of the naphthalene nucleus free, with an aroyl chloride or anhydride, such as benzoyl chloride or benzoic anhydride, by the use of AlCl_3 or a similar condensing agent in the presence of O or a gas contg. O. The condensation may be effected in a single process or in stages.

Dyes. I. G. FARBENIND. A.-G. Fr. 644,782, Sept. 27, 1927. Vat dyes of the $\text{C}_{14}\text{H}_{10}$ series are prepd. by treating with alk. agents the condensation products of anthrone or its derivs. and glyoxal or its higher homologs or bisulfite compds. or sulfure esters of other compds. yielding dialdehydes. In examples, the condensation product of anthrone and glyoxal is heated with KOH-EtOH . On pouring into water a dye is pptd., which dyes cotton bordeaux-red shades from the vat. If anthrone is replaced by 2-phenylanthrone, violet shades are obtained. The condensation products of 2-chloroanthrone and glyoxal sulfate, and of 1-chloroanthrone and glyoxal on treatment give similar shades.

Dyes. I. G. FARBENIND. A.-G. Fr. 645,548, Dec. 10, 1927. Acid wool dyes are prepd. by treating 1-amino-4-bromoanthraquinone-2-sulfonic acid (I) with a *p* amino-acetanilide contg. an alkyl group in the acetyl amino radical. In an example the Na salt of I is heated in water to $60-70^\circ$ with *p*-aminomethylacetanilide, Na_2CO_3 and CuSO_4 .

Dyes. I. G. FARBENIND. A.-G. Fr. 645,586, Dec. 12, 1927. New azo dyes are obtained by treating *o*-hydroxyazo dyes with ClSO_3H or its salts. In examples, 4-chloro-2-aminophenolazo- β -naphthol is heated to $60-70^\circ$ in PhCl and pyridine with ClSO_3H . The product dyes wool orange turning to a fast brown-red by chroming. 5-Nitro-2-aminophenolazo-2-naphthol-3-carboxylic acid is treated as in the 1st example; the product is reduced with Na_2S and transformed into a symmetrical urea by COCl_2 . * 5-Nitro-2-amino-1-phenolazo-*N*-phenyl-3-methyl-5-pyrazolone is treated as in the 2nd example, giving a product that dyes cotton orange which may be coppered. 5-Nitro-2-aminophenolazo-2-aminobenzoyl-5-naphthol-7-sulfonic acid and 5-nitro-2-amino-1-phenolazo-2-benzoylamino-8-naphthol-6-sulfonic acid are treated as in the 2nd example, giving a blue-red and a violet-red, resp., on cotton.

Dyes. I. G. FARBENIND. A.-G. Fr. 645,588, Dec. 12, 1927. Azo dyes are obtained by coupling with coupling components diazotized arylamines contg. in the aromatic ring a CN group with or without other substituents. In examples, cotton is treated in a bath contg. the 4-chloro-2-anisidide of 2,3-hydroxynaphthoic acid, which is coupled on the fiber with 5-cyano-2-toluidine. A brilliant red of excellent fastness is obtained. Similarly, the α -naphthylamide of 2,5-hydroxynaphthoic acid is coupled on the fiber with diazotized 1-amino-3-cyano-6-methylbenzene, giving a bluish red, and 4-cyano-2-amino-1-benzoic acid is diazotized and coupled with 1-hydroxynaphthalene-4-sulfonic acid giving a product which dyes wool orange from an acid bath; this turns to violet-red on chroming. A list of components and the colors produced therewith is given.

Dyes. I. G. FARBENIND. A.-G. Fr. 645,753, Dec. 15, 1927. Blue dyes of the diaminotriphenylmethane series are prepd. by condensing benzaldehydedisulfonic acids with arylamines contg. a Pr or higher group. Thus, benzaldehyde-2,4-disulfonic acid is condensed in H_2SO_4 with 2-mono-1-methylpropylamino-1-toluene. The leuco-compd. is oxidized in a known manner, and by adding NaCl a dye is pptd. which dyes

wool and silk. The 2,5-disulfonic acid and the 2-isopropylamino-1-toluene may also be condensed. The *arylamines* are obtained cheaply from 2-chloropropane or butane.

Dyes. I. G. FARBENIND. A.-G. Fr. 645,771, Dec. 15, 1927. New azo dyes are prep'd. by combining diazo, tetrazo, or diazoazo compds. in substance or on the fiber with 2,3-hydroxynaphthoyl-2-amino-3-naphthol ethers. The azo group probably enters the 1-position of the hydroxynaphthoyl radical. In examples, 4-nitro-2-amino-1-anisole is diazotized and coupled with 2,3-hydroxynaphthoyl-2-amino-3-naphthol methyl ether. A product is obtained giving a fast bluish red dyeing on cotton. Cotton is impregnated with 2,3-hydroxynaphthoyl-2-amino-3-naphthol methyl ether soln., which is developed with diazotized 5-chloro-2-amino-1-toluene soln. contg. $\text{Al}_2(\text{SO}_4)_3$. A fast bluish red color is obtained. A list of components which may be coupled with the Me and Et ethers, and the colors obtained is given.

Azo dyes. BRITISH DYE STUFFS CORP., LTD., and R. BRIGHTMAN. Brit. 294,284, April 22, 1927. Diazotized 4-nitro-4'-aminodiphenyl sulfide is used for producing monoazo dyes by coupling with an amine or phenol of the benzene series or naphthalene series, or with a sulfonic or a carboxylic acid deriv. of such a component; it may also be used to produce secondary disazo dyes by similar coupling, re-diazotization and further coupling with a suitable component. The sulfonated monoazo dyes yield on wool dyeings fast to milling; the disazo dyes are suitable for use on regenerated cellulosic materials. Dyes of either type contg. not more than 1 sulfonic group are suitable for use on cellulose esters. Several examples are given of dyes producing various orange, red, yellow and brown shades.

Azo dyes. BRITISH DYE STUFFS CORP., LTD. Fr. 645,199, Dec. 6, 1927. New trisazo dyes capable of being diazotized and developed on the fiber are prep'd. by combining a diazotized nitroarylamine or acyldiamine, with or without other substituents, with a *peri*-aminonaphtholsulfonic acid in an acid medium, then coupling in an alk. medium with a tetrazotized diamine of the benzidine series, and again coupling the resulting product with α -naphthylamine or its 6- or 7-sulfonic acids, the nitro group being reduced or the acetyl group being removed by hydrolysis. In examples, (1) *p*-nitroaniline is diazotized and coupled with H-acid, then with tetrazotized benzidine, and then with α -naphthylamine, the nitro group being reduced with Na_2S either after the first coupling or finally; (2) *p*-aminoacetanilide is diazotized and coupled with the same substances in the same order, the acetyl group being finally removed by alk. hydrolysis. Cotton is dyed with the above dyes, which are diazotized on the fiber and coupled with *m*-tolylenediamine, giving a fast deep black shade. Dyes may also be obtained from the following: *p*-nitroaniline-*o*-sulfonic acid, 5-nitro-2-anisidine, *o*-chloro-*p*-nitroaniline (or *m*-nitroaniline), H-acid benzidine and α -naphthylamine; *p*-nitroaniline, H-acid, benzidine and Cleve's acid; *p*-nitroaniline, 1,8-aminonaphthol-1-sulfonic acid, benzidine and α -naphthylamine; and *p*-nitroaniline, H-acid, dianisidine and α -naphthylamine.

Azo dyes. I. G. FARBENIND. A.-G. (Richard Stüsser, inventor.) Ger. 471,038, July 30, 1926. Two mols. of a product obtained by carefully reducing, under alk. conditions, a dye prep'd. from diazotized 5-nitro-2-aminobenzoic acid and a suitable component are coupled together through their azo or azoxy groups, disazo or polyazo dyes being obtained, which can be further diazotized and coupled in substance or on the fiber. In 1 example, diazotized 5-nitro-2-aminobenzoic acid is coupled with 2-amino-8-hydroxynaphthalene-6-sulfonic acid; reduction is effected with glucose and NaOH, and the product salted out. The diaminoazo dye so obtained is tetrazotized and coupled with 2,4-diaminoacetanilide, giving a product which dyes cotton in black shades; these can be improved by treating the dyed fiber with metal salts. In another example, the coupling component is 2-amino-5-hydroxynaphthalene-7-sulfonic acid, and the product obtained after reduction dyes cotton in violet shades. If the product is diazotized on the fiber, coupled with β -naphthol, and treated with CuSO_4 , fast blue-black shades are obtained. Other examples are given in which the initial materials are the dyes prep'd. by coupling diazotized 5-nitro-2-aminobenzoic acid with 2-phenylamino-5-hydroxynaphthalene-7-sulfonic acid, acetyl-amino-5-hydroxynaphthalene-7-sulfonic acid, and 1-8-naphthyl-3-methyl-5-pyrazolone-6-sulfonic acid. Cf. C. A. 23, 1757.

Azo dyes. I. G. FARBENIND. A.-G. Fr. 645,066, Dec. 2, 1927. Insol. azo dyes are prep'd. by coupling 4-aminoacetophenone or 4-aminobenzophenone and their substitution products with acetoacetic arylamides. In examples, 4-aminoacetophenone is diazotized and coupled with acetoacetic anilide in AcOH soln. 4-Amino-3-nitroacetophenone is diazotized and coupled with acetoacetic chloroanilide. 4-Aminobenzophenone is diazotized and coupled with acetoacetic anilide. The dyes made as oil colors and distemper colors fill a blank in the known colors of the green side of the spectrum.

Chromium compound of an azo dye. SOC. ANON. POUR L'IND. CHIM. A BÂLE. Swiss 128,006, Apr. 23, 1927. The prepn. is described of the Cr compd. of the dye prep'd. from diazotized 5-nitro-2-amino-1-phenol and 2-phenylamino-5-naphthol-7-sulfonic acid. The product dyes cotton blue. Cf. Brit. 289,094 (C. A. 23, 717).

Chromium compounds of monoazo dyes. I. G. FARBENIND. A.-G. Brit. 294,743, June 10, 1927. The dye obtained by coupling diazotized metanilic acid with salicylic acid is treated with a Cr compd. (suitably warmed with a Cr formate paste). The product dyes wool fast greenish yellow and may also be used for calico printing and for the production of Batik goods. Cf. C. A. 22, 1481.

Vat dyes. I. G. FARBENIND. A.-G. (Max A. Kunz and Karl Köberle, inventors). Ger. 470,948, Feb. 18, 1927. Addn. to 457,493. Vat dyes giving red shades on cotton are prep'd. by introducing a plurality of different halogen atoms into *allo-ms-naphthodanthrone* or its derivs. The initial material may be treated simultaneously or successively with different halogenating agents, or a halogenated *allo-ms-naphthodanthrone* may be treated with a halogen other than that already present. Solvents, diluents, and (or) halogen-carriers may be present. The prepn. of dichlorodibromo-*allo-ms-naphthodanthrone* is described by way of example.

Vat dyes. I. G. FARBENIND. A.-G. (Max A. Kunz and Karl Köberle, inventors). Ger. 470,949, Jan. 29, 1927. Vat dyes dyeing cotton in brown to violet shades are prep'd. by treating a neg. substituted *ms-anthradianthrone* with a compd. contg. a reactive NH or NH₂ group. Solvents, diluents, and (or) catalysts may be present. Examples are given describing the prepn. of dyes from (1) dibromo-*ms-anthradianthrone* and α -aminoanthraquinone, (2) chloro-*ms-anthradianthrone* and β -aminoanthraquinone, (3) dibromo-*ms-anthradianthrone* and 1-amino-4-methoxyanthraquinone, and (4) tetrabromo-*ms-anthradianthrone* and *p*-toluenesulfonamide. The prepn. of the initial materials of examples 1-3 is described in Ger. 468,988.

Vat dyes. I. G. FARBENIND. A.-G. (Max A. Kunz and Karl Köberle, inventors). Ger. 471,039, Jan. 15, 1927. Vat dyes dyeing cotton reddish brown to bluish black shades are prep'd. by treating a halogenated *ms-benzodanthrone* with a N-contg. compd. in which at least 1 reactive H atom is attached to N. Solvents, catalysts, and (or) acid-binding substances may be present. Examples are given describing the prepn. of dyes from (1) tetrabromo-*ms-benzodanthrone* and α -aminoanthraquinone, (2) tribromo-*ms-benzodanthrone* and α - or β -aminoanthraquinone, 1-amino-4-methoxyanthraquinone, or *p*-aminophenol, (3) trichloro-*ms-benzodanthrone* and α -aminoanthraquinone, (4) 4,4'-dichloro-2,2'-dimethyl-*ms-benzodanthrone* and α -aminoanthraquinone or *p*-toluenesulfonamide.

Vat dyes. I. G. FARBENIND. A.-G. (Max A. Kunz and Karl Köberle, inventors). Ger. 471,040, Feb. 19, 1927. See Brit. 285,502 (C. A. 22, 4831).

Vat dyes. LEOPOLD CASSELLA & CO. G. M. B. H. (Richard Herz and Werner Zerweck, inventors). Ger. 470,947, Oct. 19, 1926. Addn. to 458,598. See Brit. 287,020 (C. A. 23, 524).

Vat dye. SOC. ANON. POUR L'IND. CHIM. A BÂLE. Swiss 128,007, April 1, 1927. The trichloropyranthrone prep'd. according to example 3 of Ger. 218,162 is condensed with PhOH in the presence of alkali carbonate. The product dyes cotton in red shades.

Vat dyes of the 1,9-anthra-thiazole series. RALPH N. LULEK (to E. I. duPont de Nemours & Co.). U. S. 1,705,023, March 12. One mol. proportion of 1,9-anthra-thiazole-2-carboxylic acid chloride is condensed with 1 mol. proportion of a mono-aminoanthraquinone or with a diaminoanthraquinone in which 1 amino group is substituted by a benzoyl group, or 2 mol. proportions of the 1,9-anthra-thiazolecarboxylic chloride may be condensed with 1 mol. proportion of a diaminoanthraquinone, to produce vat dyes dyeing cotton from greenish yellow to brown shades. The products are of the type formula, A-CO-NH-A', in which A is always the residue of 1,9-anthra-thiazole (-CO in the 2-position) and A' may be either an anthraquinone residue in which 1 H may be replaced by halogen or a diaminoanthraquinone residue in which one amino group may be substituted by a benzoyl group. In most instances, the dyes thus produced discharge with "sulphoxite Cl" and are suitable for printing. Several examples with details of procedure are given.

Vat dyes of the pyranthrone series. HEINRICH NERESHEIMER (to Grasselli Dye-stuff Corp.). U. S. 1,703,948, March 5. *Bz, Bz'*-Diarylpyranthrone such as those described in German patent 278,424 are treated with acid condensing agents and either simultaneously or subsequently with oxidizing agents. If oxidizing agents such as MnO₂ are used simultaneously with the condensing agents, the final product is directly produced, but if acid condensing agents such as AlCl₃ are used alone, the product is first formed as a reduction product and readily oxidized to the dye even by the action of the

air. The products differ from the *Bz*, *Bz'*-diarylpyranthrones in generally possessing a more reddish color. Details of procedure are given.

Dyes of the anthracene series. I. G. FARBENIND. A.-G. (Karl Schirmacher, Wilhelm Schaich and Arthur Wolfram, inventors). Ger. 470,809, June 16, 1926. The 9,10-disulfuric esters, or their salts, of such leucoanthraquinones as have 1 or more NH_2 groups or *N*-substituted NH_2 groups in the β -position are treated in alk. soln. with oxidizing agents. Products of the acid-wool-dye type are obtained on acidification, and these products, on further oxidation under acid conditions, give vat dyes free from H_2SO_4 residues. In the example, β -aminoleucoanthraquinone-9,10-disulfonate is treated with alk. KMnO_4 . After filtering, a red-violet powder of the acid-wool-dye type is obtained by acidification. This product, when heated in aq. soln. with NaNO_2 , yields a difficultly sol. compd. which gives blue vats with alk. $\text{Na}_2\text{S}_2\text{O}_4$ from which cotton is dyed in blue shades. The intermediate product need not be isolated.

Anthraquinone dyes. I. G. FARBENIND. A.-G. Brit. 294,986, Aug. 3, 1927. Acid wool dyes are formed by condensing 1-amino-4-bromoanthraquinone-2-sulfonic acid with 4-aminoformanilide having an alkyl group such as Me or Et, or a benzyl group, in the formylamino group. The condensation may be effected by heating in the presence of water and CuSO_4 .

Indigoid dyes. I. G. FARBENIND. A.-G. (Josef Haller, inventor.) Ger. 470,759, Jan. 8, 1926. See Brit. 286,359 (*C. A.* 23, 285).

Sulfurized dyes. I. G. FARBENIND. A.-G. Fr. 645,519, Dec. 10, 1927. Pastes of sulfurized dyes of no matter what thickness, with or without the addn. of Na_2S , are made by adding to the compressed cakes a carbohydrate capable of swelling under the action of alkalis—*e. g.*, starch—in such quantity that a homogeneous paste is produced from which neither water nor crystals sep. Substances such as cresol may be added to prevent mold formation and to make the starch sol. Hygroscopic agents may also be added.

Triarylmethane dyes. BRITISH DYESTUFFS CORP., LTD. Fr. 645,351, Dec. 7, 1927. In the prepn. of Lissamine green V (Color Index No. 735) from tetraethyldiaminobenzohydrol and 2,7-naphthalenedisulfonic acid, the hydrol is isolated as its 2,7-naphthalenedisulfonate. In an example, tetraethyldiaminodiphenylmethane is oxidized with PbO_2 to form the hydrol, and after removing the Pb, Na 2,7-naphthalenedisulfonate is added and the liquid acidified with H_2SO_4 . The pptd. disulfonate is washed and dissolved in H_2SO_4 , the leuco dyestuff obtained by heating and pouring into water being oxidized with PbO_2 in the usual manner.

Dyes of the benzanthrone series. ARTHUR LÜTTINGHAUS, HEINRICH NERESHEIMER and HUGO WOLFF (to Grasselli Dyestuff Corp). U. S. 1,704,983, March 12. The intermediate product of an incomplete alk. condensation of about equimol. proportions of a benzanthrone compd. with free 2- and *Bz*-1-positions and a *Bz*-1-halogen-benzanthrone with free 2-position (the intermediate product itself still having free *Bz*-1'- and 2-positions) is subjected to further alk. condensation until a vat dye is obtained. Several examples with details of procedure are given. Cf. *C. A.* 23, 1757.

Dyes and intermediates. L. J. HOOLEY, J. THOMAS and SCOTTISH DYES, LTD. Brit. 294,672, Jan. 29, 1927. Dyes or intermediates for dye manuf. are formed by sulfonating either (a) leuco compds. of anthraquinone or vat dyes derived from anthraquinone, *e. g.*, dibenzanthrone, and their derivs. contg. acyclic substituents such as OH, NH_2 , or alkylamino groups, or (b) leuco compds. of indigoid dyes. Several examples are given of the production of dyes of various colors.

Dye intermediates. COMPAGNIE NATIONALE DE MATIERES COLORANTES ET MANUFACTURES DE PRODUITS CHIMIQUES DU NORD REUNIES, ETABLISSEMENTS KUHLMANN. Brit. 294,462, July 23, 1927. Halogenated aromatic carbocyclic and heterocyclic bases are obtained by halogenation of the corresponding sulfoamido derivs. derived from aryl sulfonic acids, and subsequent hydrolysis of the halogenated sulfonamide obtained. Nitro groups or other substituents may be introduced before or after halogenation (chlorination), and substituents already present in the chlorinated sulfonamides may be replaced by others, *e. g.*, by reducing NO_2 groups. Several examples are given. Arylsulfonamides of aromatic carbocyclic and heterocyclic bases may be made by condensation of the corresponding bases with aryl sulfonylchlorides as benzene-, *o*- and *p*-toluene-, *o*-nitro-*p*-toluenesulfonyl chlorides or with the mono- or poly-sulfonylchlorides of naphthalene, or by condensation of aryl sulfonamides with aromatic compds. contg. a mobile substituent in the nucleus. Various examples are given.

Alkylisorosindulinesulfonic acids. PAUL LUGER (to J. R. Geigy, S. A.). U. S. 1,703,772, Feb. 26. By the treatment of a 1-chloro-3-dialkylisorosinduline deriv. in an org. solvent such as alc. with a sulfite soln., and subsequent oxidation, dialkyliso-

rosinduline-1,6-disulfonic acids are obtained, which are blue dyes sol. in water, dyeing wool blue in an acid bath, and which are suitable for use as *intermediates* for making naphthosafranine dyes.

***o*-Aminodiaryl ethers.** ARTHUR ZITSCHER (to Grasselli Dyestuff Corp.). U. S. 1,703,915, March 5. 5,2',5'-Trichloro-2-aminodiphenyl ether is made by reacting with an alkali metal salt of 2,5-dichlorophenol on 3,4-dinitro-1-chlorobenzene and treating the *o*-nitrodiaryl ether thus formed with a reducing agent. It m. 74-5° (not corrected). The corresponding nitro compd., m. 97-8°. This and other related compds. similarly formed may be used as *dye intermediates*.

2,3- and 2,5-Dichloro-4-amino-1-methylbenzene. I. G. FARBERIND. A.-G. Brit. 294,078, Jan. 24, 1928. 2-Chloro-4-acetamido-1-methylbenzene is treated with Cl in the presence of a mixt. of HOAc and water with cooling; 2,5-dichloro-4-acetamido-1-methylbenzene is pptd. in a substantially pure state and 2,3-dichloro-4-acetamido-1-methylbenzene is pptd. from the mother liquor by use of water; these compds. are treated with a saponifying agent. The products may be used as *intermediates* for making azo dyes.

Quinone anilides. I. G. FARBERIND. A.-G. (Maximilian P. Schmidt and Eberhard Elbel, inventors). Ger. 470,760, July 22, 1926. Quinone anilides are prepd. by heating *p*-hydroxyazo dyes in aq. soln. or suspension in the presence of acid substances. In an example, an AcOH soln. of the dye from diazotized metanilic acid and α -naphthol is boiled for 10 hrs., Na 1,4-naphthoquinone-2-anilido-*m*-sulfonate being obtained on salting out. 1,4-naphthoquinone-2-*p*-anilidosulfonic acid can be prepd. similarly from orange 1 (*p*-sulfobenzeneazo- α -naphthol).

Derivatives of arylaminonaphthalenes. I. G. FARBERIND. A.-G. Fr. 645,150, Dec. 5, 1927. Derivs. of arylaminonaphthalenes are prepd. by treating at high temps with or without pressure, amino- or hydroxy-naphthalenes, excepting their sulfonic or carboxylic acids or 1,8-diaminodihydroxy or aminohydroxy derivs., with amino benzene derivs., which are substituted with an amino or hydroxy group and which may contain other substituents. Instead of the aminobenzene the corresponding nitrobenzene may be used, and the nitro group reduced by the addn. of HCOOH during the condensation. The products are *intermediates* for dyes. They impregnate animal fiber and by subsequent oxidation form fast dyes. In examples, (1) 2'-aminophenol-2-aminonaphthalene, m. 96-97°, is prepd. by heating 2-hydroxynaphthalene and 1,2-diaminobenzene with Na₂SO₃ soln.; (2) 2-(4-aminophenylamino)-7-hydroxynaphthalene is formed from 1,4-diaminobenzene and 2,7-dihydroxynaphthalene; (3) 2-naphthyl-4,4'-diaminodiphenylaminosulfonic acid is formed from 2-hydroxynaphthalene and 4,4'-diaminodiphenylamino-2-sulfonic acid; (4) (4-hydroxyphenyl)-1-aminonaphthalene, m. 91°, is formed from 1-aminonaphthalene and 1-amino-4-hydroxybenzene; (5) (4-hydroxy-3-methylphenyl)-2-aminonaphthalene, m. 127-128°, is formed from 2-hydroxynaphthalene and 4-amino-1-hydroxy-2-methylbenzene; (6) (4-hydroxyphenyl)-2-carboxy-2-aminonaphthalene, m. 172-174°, is formed from 2-aminonaphthalene and 4-amino-1-hydroxy-2-carboxybenzene; (7) 2,7-di-(*p*-hydroxyphenylamino)-naphthalene, m. 249-250°, is formed from 2,7-dihydroxynaphthalene and 4-amino-1-hydroxybenzene; (8) 1,5-di-(*p*-hydroxyphenylamine)naphthalene is formed from 1,5-dihydroxynaphthalene and 4-amino-1-hydroxybenzene. A list of other constituents which may be used is given.

Pyrazolanthrone derivatives. I. G. FARBERIND. A.-G. Fr. 644,589, Oct. 21, 1927. Derivs. of pyrazolanthrone (I) which are of value in the *dyeing* industry are prepd. by treating (I), in which the H of the NH group may be replaced by a metal, or homologs, derivs., or substitution products of (I) by halogen derivs. of the C₆H₅, C₁₀H₇, etc., series or of the anthraquinone series, with or without diluents and a catalyst such as Cu or a salt thereof. In examples, equal parts of (I) and PhBr and K₂CO₃ are heated in PhNO₂ under reflux in the presence of Cu. A phenylpyrazoleanthrone in which the phenyl group replaces the H of the NH group is obtained. Phenylpyrazoleanthrone-*o*-carboxylic acid is obtained from (I) and *o*-bromobenzoic acid. Naphthylpyrazoleanthrone-*o*-carboxylic acid, m. 277-279°, is obtained from (I) and 2-chloro-3-naphthoic acid. Other examples are given using (I) and *o*-chloronitrobenzene, *Bs*-1-bromobenzanthrone, *Bs*-1-chloro-*Bs*-2-phenylbenzanthrone, *Bs*-1-bromobenzanthrone nitrated at 202°, 2-chlorobenzanthrone, α -chloroanthraquinone and α -bromonaphthalene, in each case a condensation between the 2 substances taking place with elimination of HBr or HCl. An example is given of the condensation of dipyrazoleanthrone with *Bs*-1-bromobenzanthrone, in which one radical of the latter becomes attached to each of the pyrazole rings, and of the condensation of (I) with 1,5-dichloro-2,4-dinitrobenzene, in which case each of the Cl atoms becomes replaced by a radical of (I). 4-Methylpyrazoleanthrone may be used instead of (I).

Condensation products of naphthostyryls. I. G. FARBENIND. A.-G. Fr. 644,947, Nov. 30, 1927. Naphthostyryl or one of its substitution products is condensed by means of acid condensing agents with an aromatic compd. contg. at least one nuclear H atom capable of reacting, particularly a uni- or multivalent phenol, or with a tertiary amine, in which one of the C atoms linked to the N forms part of an aromatic ring; the products are *dyes*. Sulfonation of the condensation products gives *acid dyes for wool*. In examples, naphthostyryl, PhNMe_2 and POCl_3 are stirred at the ordinary temp. in the absence of moisture and afterward heated to 100° . The mass is made alk. and distd. with steam. The product dyes mordanted cotton or wool a violet-blue shade. PhNMe_2 may be replaced by *m*-diethylaminophenetole or *m*-chlorodimethyl (or ethyl)aniline or PhCl or tetramethyl-*o* (or *p*)-phenylenediamine or *N,N*-dimethyl-1,2,3,4-tetrahydroquinoxaline. The dye obtained by using the last-mentioned substance is sulfonated with oleum, giving a product which dyes wool in blue shades. The condensation product of pyrogallol and naphthostyryl, when sulfonated, dyes wool yellow; this turns brown on washing and a brilliant orange-red on chroming.

Dye for leather. JEAN DESCOMBES. Fr. 644,637, Nov. 26, 1927. Stearate or oleate is used as a dye for leather.

Fixing basic dyes. I. G. FARBENIND A.-G. Brit. 294,286, April 22, 1927. The fastness to light of dyeings with basic dyes is improved by treating the dyed material with reduction products of the complex phospho-molybdo-tungsten compds. described in Brit. 292,253 (C. A. 23, 1512.)

Sulfonated fatty acids. I. G. FARBENIND. A.-G. Fr. 645,221, Dec. 6, 1927. Products which are used principally in *dyeing* in place of Turkey-red oils are prepd. by treating unsatd. fatty acids with oleum with the addn. of a lower fatty acid or its anhydride or esters. Thus, to a mixt. of castor oil and glacial AcOH fuming H_2SO_4 (27%) and Ac_2O are added at about 0° . The product is poured into ice water contg. Na_2SO_4 . Chloroacetic acid or AcOMe may also be used.

Dyeing. J. G. KERN and C. J. SALA (to E. I. Du Pont de Nemours & Co.). Brit. 205,025, Aug. 4, 1927. Aliphatic amines contg. 1 or more hydroxyalkyl or dihydroxy-alkyl groups (such as hydroxyethyl or hydroxybutyl groups) attached to the N atom are used as assistants in vat dyeing, either by incorporation in the dye pastes or by addn. to the vats; more even dyeings are obtained especially by padding methods. Several examples of the process are given.

Dyeing. I. G. FARBENIND. A.-G. Fr. 645,667, Dec. 2, 1927. The absorptive capacity of wool and silk for acid or neutral colors is reduced by a pretreatment of the fibers with products obtained by sulfonating resins or by adding these products to the dye bath. Examples are given of the use of colophansulfonic acid in dyeing mixed fibers.

Dyeing. HERMINGHAUS & CO., G. M. B. H. Fr. 645,031, Dec. 1, 1927. To prevent parts of cloth contg. cellulose absorbing certain dyes, the cloth, previously dampened or treated with alkali, is treated with POCl_3 . The POCl_3 may be ins. oln. in CCl_4 or as a gas or in a current of moist air.

Dyeing cloth. HENRI J. ALET. Fr. 645,808, Dec. 16, 1927. Cloth is dyed by passing it under tension over the narrowed top of a dye bath, the dye being absorbed into the cloth by capillary attraction; it is collected in a warm, damp atm.

Dyeing silk. BRITISH DYE STUFFS CORP., LTD. Fr. 645,384, Dec. 8, 1927. Regenerated cellulose silks are dyed by the known secondary disazo dyes obtained by coupling diazotized *p*-nitroaniline-*o*-sulfonic acid with a middle component, re-diazotizing and coupling in acid or alk. soln. with 2-amino-5-naphthol-7-sulfonic acid or its *N*-alkyl, *N*-aryl, or *N*-acyl derivs. As middle components, α -naphthylamine and *m*-amino-*p*-cresol methyl ether, and as end components, the 2,5,7-acid itself or its *N*-ethyl, *N*-phenyl, or *N*-acetyl derivs. are used. Cf. C. A. 23, 528.

Dyeing and printing acetate silk. I. G. FARBENIND. A.-G. (Oskar Spengler, Paul Vreck and Rudolf Weidenhagen, inventors.) Ger. 470,849, Dec. 4, 1924. Acetate silk is dyed or printed by treating it, in the presence of NH_3 or an aliphatic amine and in the presence or absence of an oxidizing agent, with such arylamines or their derivs. as form colored compds. under the conditions specified. The arylamines may be mixed with amino- or hydroxy-aryl compds., which form colored compds. under the conditions specified. Examples are given describing the use of 4,4'-dihydroxydiphenylamine, 3',5'-dichloro-4'-amino-4-hydroxydiphenylamine, 4'-amino-4-hydroxydiphenylamine, 4'-dimethylamino-4-hydroxydiphenylamine, *p*-phenylenediamine alone and with PhOH and PhNMe_2 , 4-aminodiphenylamine, 2-*p*-hydroxyphenylaminonaphthalene, and PhNMe_2 with *p*-aminophenol.

Dyeing vegetable fibers. FRITZ STRAUB (to Soc. anon. pour l'ind. chim. à Bâle).

U. S. 1,704,637, March 5. Fast dyeings are obtained by use of dyeing baths prepd. with Cr compds. of azo dyes prepd. from diazo compds., which contain, in the *o*-position to the diazo group, a group adapted to the formation of lakes. Numerous examples are given.

Dyeing vegetable fibers with aniline black. K. SCHMIDT. Brit. 294,554, Jan. 24, 1927. In dyeing by the use of a padding liquor or printing paste contg. aniline salts, oxidizing agents, metallic catalysts, org. catalysts and salts of weak or easily oxidizable acids which protect the fiber, the ratio of the latter to the aniline salt is at least 2:5. Examples are given. Cf. C. A. 23, 1513.

Dispersing agents for use in dyeing cellulose esters and for other purposes. J. G. KERN and C. J. SALA (to E. I. Du Pont de Nemours & Co.). Brit. 295,024, Aug. 4, 1927. Soap-like products are obtained by the interaction of aliphatic acids or their derivs., such as their glycerides or sulfonic acids, with hydroxyalkylamines; *e. g.*, oleic acid may be treated with a mixt. of di- and tri-ethanolamine, 1-amino-2,3-dihydroxypropane or monomethyldihydroxyethylamine; or stearic acid may be treated with triethanolamine. The products are solvents and detergents and have greater dissolving and dispersing powers than ordinary soaps or sulfonated oils. They are suitable for use with metallic oxides or hydroxides, etc., in forming *antiseptic soaps*. Examples are given of their use for prepg. dispersions suitable for dyeing cellulose esters.

Apparatus for dyeing yarn, especially warp yarn in hanks. THOMAS MCCONNELL. Ger. 470,920, Sept. 19, 1925.

Apparatus for dyeing warps or fabrics wound on perforated holders in graduated shades. ALBERT HERZOG and HEINRICH KÜNZEL. Ger. 470,919, Dec. 11, 1925.

Means for squeezing hanks after dyeing. MARIE P. L. A. ROUEN. Ger. 470,924, Nov. 21, 1925.

Hanging device for use in the wet treatment of textiles, particularly in dyeing stockings. FRIEDRICH G. GNÜCHTEL. Ger. 471,016, Mar. 9, 1926.

Apparatus for the wet treatment of hanks. THE NUERA ART-SILK CO., LTD. Ger. 471,017, Feb. 8, 1927.

Apparatus for applying colors in sequence for dyeing yarn on a reel. J. BRANDWOOD. Brit. 294,504, Jan. 22, 1927.

Coloring cellulose esters and ethers. SOC. CHIMIQUE DES USINES DU RHONE and M. J. THEUMANN. Brit. 294,137, April 12, 1927. The process described in Brit. 275,553 (C. A. 22, 2279) is used for the dispersion in the cellulose esters or ethers of lakes of org. coloring substances. An example is given of the coloring of cellulose acetate in acetone soln. by the use of eosin and an aq. soln. of Pb acetate.

Apparatus for dyeing and bleaching textile goods. ZITTAUER MASCHINENFABRIK A.-G. (Julius Ernestus, inventor). Ger. 470,799, Oct. 20, 1926. Improvements are described in an app. of the kind comprising an open partitioned tank having liquid-circulating means.

Pressure regulator for circulatory dyeing apparatus. BRATKÍ JOKLOVÉ, TUCHFABRIK. Ger. 470,921, June 4, 1926.

Apparatus for treating cakes of artificial silk with washing, dyeing, soaping or other liquids. * COURTAULDS, LTD., H. J. HEGAN and E. HAZELEY. Brit. 294,279, April 21, 1927.

Mordanting. HENRY DREYFUS. Fr. 644,936, Nov. 30, 1927. Material consisting of, or contg. esters of cellulose, *e. g.*, cellulose acetate, are mordanted before dyeing with relatively concd. (20-40% or more) solns. of mordanting salts, such as salts of Al, Cr, or Sn. If the temp. used is such as would cause delustering, agents preventing delustering are added. Fr. 644,937 describes a process of mordanting in which aliphatic acid salts of the metals such as acetates, lactates, glycolates or citrates of Al or Ca are used, the concn. being 15% or more. Cf. C. A. 23, 1759.

Textiles. GEORG DIETRICH. Fr. 645,848, Dec. 17, 1927. Artificial silk threads are mixed with "wild African silk," particularly that known as "Anaphé," and spun.

Finishing textile fabrics. J. J. LAMBRECHT. Brit. 294,101, July 16, 1927. See Fr. 637,772 (C. A. 23, 529).

Finishing fabrics comprising thermoplastic derivatives of cellulose. C. DREYFUS and C. W. PALMER (to British Celanese, Ltd.). Brit. 295,035, Aug. 4, 1927. Fabrics contg. thermoplastic cellulose derivs., either alone or together with cotton, silk, or wool, are ironed or calendered while dry at a temp. of 100° or higher, to effect smoothing without increase of luster. Delustering and low-temp. drying may precede this treatment.

Finishing fabrics containing thermoplastic cellulose derivatives. C. DREYFUS (to British Celanese, Ltd.). Brit. 295,043, Aug. 4, 1927. Delustered fabrics, or threads

contg. substances such as cellulose acetate, formate, propionate or butyrate, or methyl or ethyl cellulose, either alone or mixed with silk, cotton, or wool, have their luster restored by ironing or calendering them while damp. Mottled effects may be produced by dampening only portions of the materials.

Mercerizing mixed fabrics. BLEACHERS' ASSOCIATION, LTD., W. KERSHAW, F. L. BARRETT, C. J. WHITELEGG and G. D. SUTTON. Brit. 295,062, May 9, 1927. Mixed fabrics of cotton and regenerated cellulose such as viscose or cuprammonium "silk" are mercerized under tension with alkali in the usual manner, and the mercerizing liquor is washed off at a controlled temp. above 50°. The luster of the viscose product is thus but slightly affected while the cotton fibers are "leveled up."

Treating mercerized fabrics. C. A. GRUSCHWITZ A.-G. Ger. 470,922, Sept. 17, 1926. An app. is described whereby the selvages on both sides of a fabric which has left the mercerizing bath and is not under tension are squeezed and then pressed hot. The usual treatment of the whole fabric follows.

A new cloth. VICTOR GREIDENBERG. Fr. 644,899, Nov. 30, 1927. Shreds of ostrich feathers are combined with metallic threads, silk, hemp, or straw to make a cloth.

Washing and other liquid treatments of artificial silk. I. G. FARBENIND. A.-G. Brit. 294,657, July 29, 1927. In the "bobbin system" of manuf., permeable spools are used; the body of each spool has a cushion of rubber or other material such as a permanent layer of threads, or both; this prevents damage from shrinkage of the inner layers of the threads treated on the spools.

Washing and other liquid treatments of artificial threads wound on spools, etc. I. G. FARBENIND. A.-G. Brit. 294,547, July 25, 1927. Spools used may be formed of iron or Ni, and the spools or assoc. devices may be handled by an electromagnetic lifting device. Brit. 294,548 also describes an app. for washing artificial silk on spools.

Device for dampening silk or similar filaments for use on textile machines. HERMANN J. SCHWABE. U. S. 1,705,212, March 12.

"Artificial wool" from vegetable fibers. GINO M. ROSSATI and GIUSEPPE DE BLASIO. U. S. 1,703,693, Feb. 26. Fibers such as jute are immersed in a clear lime water and then treated with SO₂, NaOH soln., a bleaching agent and a sulfonated fatty acid.

Wetting, cleansing and emulsifying agents. I. G. FARBENIND. A.-G. Fr. 645,395, Dec. 8, 1927. Salts formed by the combination of org. N bases with sulfonic acids or org. compds., or with fatty acids or naphthene acids, or with sulfonic acids of the nature of Turkey-red oils are used as wetting agents or as cleansing and emulsifying agents. In examples, equiv. quantities of NaOH and pyridine are added to sulfonated oleic acid, and pyridine is added to dibutyl-naphthalenesulfonic acid; in both cases the products have excellent wetting properties toward fibers. The corresponding salts of isobutylamine, PhNH₂, PhNMe₂, and triethanolamine may be prepd.

Bleaching rags, etc. F. W. BINNS (to Virginia Smelting Co.). Brit. 295,007, Aug. 6, 1927. Rags, yarns, or wastes of wool, cotton, rayon, silk, etc., are bleached and prepd. for dyeing or re-dyeing by treatment with a soln. obtained by treating Zn dust 28 lbs. in water 42 gals. with SO₂ 40 lbs., with or without addn. of CH₂O 1.5 lbs. The materials may be preliminarily boiled in two successive baths of dil. aq. NH₃ soln.

Waterproofing and preserving composition for fabrics and leather. RUDOLF KOLLER. Austrian 112,121, Sept. 15, 1928. The preferred compn. comprises Para rubber 1, dammar resin 3, beeswax 2, camphor 2 and a solvent, e. g., toluene, 92 parts.

Chlorination of animal fiber. ERICH BÖHM. Fr. 644,946, Nov. 30, 1927. Hair or wool or substances made therefrom are chlorinated by means of a soln. contg. about 3% HCl and 1% of a chlorate, with the object of improving their appearance or to allow them to be milled or felted. Oxalic or tartaric acid may also be added.

Treating felt and felt-hat bodies. ERICH BÖHM. U. S. 1,705,437, March 12. An aq. soln. of an org. tanning agent such as "neradole" is applied to the material in order to improve its luster and firmness.

Detergent. J. J. LEWIS. Brit. 294,767, July 20, 1927. A compn. suitable for use in washing clothes is prepd. by boiling together rock lime 1 lb., "common soda" 1 lb. and water 1 gal., and filtering. The product is dild. with water and used with soap.

Purifying solvents used for "dry cleaning." ARTHUR E. HAYFIELD (one-half to Achille Serre, Ltd.). U. S. 1,704,604, March 5. See Brit. 266,850 (C. A. 23, 876).

26—PAINTS, VARNISHES AND RESINS

A. H. SABIN

Specifications for paints and methods of testing employed by the German Imperial Railway Company (Deutschen Reichsbahn-Gesellschaft). M. SCHULZ. *Z. angew. Chem.* 41, 760-7(1928).—A lecture outlining the materials specified for use in various kinds of paints employed by a very large railway system, and the results obtained from weathering tests conducted with these substances. W. C. EBAUGH

Experiments on protective coatings in sea water. CARL BÄRENFÄNGER. *Korrosion u. Metallschutz* 4, 193-200(1928).—Porcelain plates were coated with various paints and placed in the waters of the Kiel canal. Conclusion: There is no good paint for lock gates, although bituminous coatings seem best. B. E. ROETHELT

Nitrocellulose paints and varnishes and the Landes forests. MAURICE DESCHIENS. *Bull. inst. pin* No. 56, 32-40(Jan., 1929).—A review of the raw materials used and of their properties, and of the compn. and prepn. of nitrocellulose varnishes and paints. A. PAPINEAU-COUTURE

Apparatus for the observation of changes in electrical conductivity of immersed paint films. G. H. STANLEY. Univ. of the Witwatersrand, Johannesburg. *S. African J. Sci.* 25, 111-5(1929).—The app. consists of a tin plate, the interior of which is painted with the paint under examn. and partly filled with the water in regard to which the tests are made. The plate constitutes the cathode. The other electrode is formed of a piece of stiff Pt wire, the lower end of which is bent into a loop after having threaded upon it a no. of small pieces of glass tubing; the plane of the loop is at right angles to the length of the wire. The loop rests on the paint surface but does not exert any pressure on it. All the paints tested showed violent fluctuation of cond. during the first few days, or hrs. of immersion. Thereafter there is a general irregular rise tending to a limit. With oil paints, the cond. rose continually till the paint cracked and stripped off. The cond. of bituminous or enamel paints increases slowly to a max., then decreases. Cellulose lacquer shows a continuous increase. An acid-proof paint broke down completely. ALBERT L. HENNE

Testing paint films. E. RITTER. *Kali* 23, 10-12, 26-7(1929).—The comparative value of paint films from the standpoint of resistance to attack by alkalis and salt solns. is detd. by measurement of elec. cond. when partially immersed in the solns., which act as electrolytes. The film is painted upon a metal strip which serves as one electrode, a C rod being the other. A machine is also described in detail which subjects test specimens to accelerated weather-exposure conditions, ultra-violet rays being used in conjunction with variation in humidity and temp. as well as the action of alkalis. Results are obtained in 32 to 64 hrs. A new method for detecting and measuring the attack on paint films is described as follows: Glass plates are coated with a Ag_2CrO_4 gelatin emulsion, and the film to be tested is painted on this. If the chloride solns. attack the film, AgCl is pptd. in the emulsion, is easily detected and the extent of the action measured. If the attack is by some other agent or by weather conditions, the test pieces can be dipped in chloride solns. at intervals and even slight attack easily detected. H. STOERTZ

The aging of paint films. A. V. BLOM. *Farben-Ztg.* 34, 892-5(1929).—The aging of films is an irreversible process involving an increase in particle size. Therefore any influence which tends to increase particle size tends to age the film. Temp. change is probably the most important factor. Aging manifests itself by increase in brittleness, and decrease both in tensile strength and in adhesion. B. outlines a method of test in which films prepd. on annealed iron test pieces $170 \times 25 \times 1$ mm. are subjected to elongation tests. The film is observed under a lens while undergoing the test, which is discontinued upon the appearance of fractures. Photomicrographs of typical specimens are given and interpreted. G. G. SWARD

The behavior of white pigments toward ultra-violet light. C. P. VAN HORCK. *Farben-Ztg.* 34, 833-4, 895-6, 954-6, 1006-9(1929).—H. has extensively reviewed the literature and cites 88 references. G. G. SWARD

Specific gravity of linseed oil. F. FRITZ. *Farben-Ztg.* 34, 24-8(1928); cf. *C. A.* 23, 531.—An exhaustive review of the published values for the sp. gr. (and temp. coeff.) of linseed oil. B. C. A.

Polish linseed oil compared with that from La Plata. Z. LEPPERT. *Przemysl Chem.* 13, 23-5(1929).—Linseed oils from La Plata are compared with those of Polish and Lithuanian origin on the basis of the usual consts., which are, resp.: congealing temp. -12° to -16° vs. -25° to -27° ; acidity no. 4 to 5 vs. 2 to 3; I_2 value (Hubl)

176 to 179 vs. 181 to 190. These differences are reflected in various industrial applications and manuf.; e. g., the Polish oils dry far better than those from La Plata. The com. interests have been so eager to absorb the Polish production of linseed oil that some Polish factories are obliged to substitute inferior imported oil for domestic product, which is exported.

A. C. ZACHLIN

Tung oil. II. D. HOLDE, W. BLEYBERG AND M. A. AZIZ. *Farben-Ztg.* 33, 3141-4(1928); cf. C. A. 23, 1761.—The I value (Hanus) obtained for eleostearic acid is influenced by the time of reaction (*loc. cit.*), the presence of light, and the mode of prepn. of the I-Br reagent. Attempts were made to det. the extent of halogen substitution or secondary dehalogenation by detg. the halogen acids in the reaction mixt. after titration with thiosulfate. Only one-fourth to one-fifth of the I apparently absorbed could be accounted for by the halogen retained by eleostearic acid; the remainder was recoverable from the aq. soln. and appeared to be due, at least in part, to a secondary elimination of halogen acid. It could not be ascertained at what stage in the Hanus test this sepn. occurred, but it is suggested that there is a tendency for the 6-membered chain constituting the triple conjugated linkings to close, by the addn. of halogen to the terminal C atoms and subsequent elimination of halogen hydride, leaving hydroaromatic or aromatic derivs.

B. C. A.

Manufacture of cellulose-ester varnishes. O. PRAGER. *Chem. Techn. Fabr.* 26, 15 8(1929).

B. C. A.

Lacquer diluents. A. NOLL. *Farben-Ztg.* 33, 3260-5(1928).—The analysis of various mixts. of aliphatic and aromatic hydrocarbons and alc. solvents is described. Qualitatively, EtOH is detected by formation of its benzoate, benzene by formation of nitro compds. and color reactions, and petroleum hydrocarbons by insoly. on nitration or sulfonation. Examn. of a series of exptl. mixts. demonstrates that "total benzol" content can be obtained with sufficient accuracy for the present purpose either by nitration or sulfonation. In the complete scheme of analysis propounded alc. constituents are detd. by absorption by CaCl₂ soln., the alc. in the aq. layer being obtained, if desired, by distn. methods, and hence the water by difference. The hydrocarbon residue is then nitrated or sulfonated, giving the aromatic content directly and the aliphatic by difference. Typical test reports are quoted, the results of which are to be considered as complementary to such tests as rate of evapn., distn. range, etc.

B. C. A.

Injury to health caused by lacquer solvents. G. SIEBERT. *Z. angew. Chem.* 42, 17-9(1929).—The use of hydrocarbons and their halogen derivs. instead of turpentine in lacquers is often attended with danger. This is due to their action as fat solvents and consequent effect upon cell structure. Tetrachloroethane (now used but little) is one of the most poisonous. Trichloroethylene is essentially harmless. CCl₄ does not have a great physiol. action. Chloroacetone is sometimes developed in the lacquer itself; although not a solvent it adds danger to such materials, as when acetone and Cl derivs. are used together in lacquer manuf. C₆H₅Cl has also been replaced largely by less dangerous solvents. C₆H₆ is much more poisonous than its homologs. Benzene seems to be in about the same class as turpentine.

W. C. EBAUGH

Manufacture of lacquers, varnishes and driers. F. S. SCHMITT. *Mal. grösSES* 20, 8287-9, 8372-3(1928), 8397(1929); cf. C. A. 22, 3999.—A review of the manuf., properties and uses of these products.

P. THOMASSET

United States Government Master Specification for shellac. ANON. *Separate*, 7 pp.

E. H.

Fluorescence of resins to filtered ultra-violet light (DRAGONE) 3. Dyes [varnish colors] (Brit. pat. 294,583) 25. Sheet material containing synthetic resin (U. S. pat. 1,703,414) 18. Cr compounds [for rust-proof paints] (Brit. pat. 294,965) 29.

MATTHISON, A. L.: **Stoving Finishes for Tin Plate Decorators and Tin Box Manufacturers.** Birmingham, Eng.: Silk and Terry, Ltd. 112 pp. 10s. 6d.

SMITH, STANLEY: **The Cellulose Lacquers.** New York and London: Isaac Pitman & Sons. 145 pp. \$2.25. Reviewed in *Bull. Imp. Inst.* 26, 526-7(1928).

Paint. JOHN C. CARROLL. Fr. 645,440, Dec. 8, 1927. An anti-corrosive paint resistant to heat comprises a powd. ore of Ti and a suitable liquid carrier. Thus, ilmenite is powd. and freed from moisture, ground up in crude linseed oil, then cleared with a mixt. of thick oil, ordinary varnish oil and alc.

Paints and pigments. E. ASSER. Brit. 294,436, Jan. 9, 1928. Permanent pastes contg. red oxide of Pb and a liquid binder such as linseed oil are prepd. by the addn. of a neutral or basic, resinic or fatty acid salt of Al which has undergone colloidal swelling, or infusorial earth, or both. Siccatives may be added and also oils and solvents to form paints and varnishes.

Rotary furnace for calcining lithopone. WILLIAM J. LINDSAY (to E. I. duPont de Nemours & Co.). U. S. 1,704,482, March 5. A furnace is described suitable for use in a calcining process specified in U. S. 1,704,483, according to which the lithopone is passed through the furnace in contact with a nonreactive gas such as water gas, which is heated to above the necessary calcining temp. so that it may supply all the heat necessary for the calcination. Sufficient gas pressure may be maintained within the app. to prevent undesired leakage into it from the exterior.

Drying color prints. KARL H. SCHWIMMER. Fr. 645,595, Dec. 12, 1927. Monochrome and polychrome printed copies contg. dyes mixed with drying oils are dried by means of rays from a quartz or like lamp.

Coating for boilers, refrigerating apparatus, etc. ALLGEMEINE ELEKTRICITÄTSGES. (to International General Electric Co.). Brit. 294,240, July 22, 1927. Coatings are applied comprising reaction products of multivalent aces. and polybasic acids with the addn. of substances which may catalytically aid the reaction, and with or without fillers such as kaolin, quartz, barites, mica or asbestos. Metal oxides may serve as catalysts and drying oils also may be added.

Varnishes. I. G. FARBENIND. A.-G. Brit. 294,911, April 29, 1927. Hard resins such as copals are incorporated with cellulose ester lacquers by use of softening agents (other than fixed oils) such as camphor, triaryl phosphates and neutral Et, Pr, Bu or Am phthalates. Various solvents and other substances may also be used and several examples with proportions of ingredients are given. Cf. C. A. 23, 532.

Varnishes for printing plates, etc. J. R. GUERARD. Brit. 294,987, Aug. 3, 1927. In prepg. printing plates or decorating articles, a support is coated with a varnish permeable to water, sufficiently friable to permit a design to be cut through it to expose the support but convertible by moderate heating into a hard and impermeable layer without melting. A mixt. formed from a soln. of a cellulose ester or ether in acetone and an alc.-ether soln. of gum resins may be used. In treating supports of metals such as Zn, Al or Cu, the metal may preliminarily be given a dark coating as by dipping into a bath formed of KMnO_4 and HCl.

Preserving flowers, leaves, fruits, etc. E. ELÖD and W. BLÜCHEL. Brit. 295,052, Aug. 6, 1927. "Cellulose varnishes," contg. plastifiers, or oil or resin varnishes or various mixts. of these may be applied by dipping, spraying, etc.

Compositions containing cellulose esters or ethers. G. TRÜMLER. Brit. 294,262, July 21, 1927. A "knifing" compn. is prepd. by adding a metal powder such as a Cu bronze powder or Al or iron to a cellulose ester resin lacquer or the like to which other fillers such as kieselguhr, mica or lithopone also may be added.

Cellulose ester lacquers. G. TRÜMLER. Brit. 294,261, July 21, 1927. Lacquers such as those contg. cellulose nitrate or acetate are formed with a "fairly high b. p." solvent such as diacetone alc., miscible with water, together with one or more water-miscible non-solvents or poor solvents such as EtOH and may also include other substances such as toluene, BuOAc, fillers, softeners, xylene, coloring agents, etc.

Colored cellulosic lacquers. I. G. FARBENIND. A.-G. Brit. 294,912, April 29, 1927. Colored cellulose deriv. compns. such as those described in Brit. 247,288 (C. A. 21, 649) and Brit. 293,485 (C. A. 23, 1749) are dissolved in mixts. contg. a butyl or amyl ester and benzene hydrocarbons or their halogen derivs. with a b. p. above 100° preferably with the addn. also of an aliphatic alc. contg. 4 or more C atoms in the mol. Other substances also may be added and an example is given.

Colored pyroxylin lacquers, etc. I. G. FARBENIND. A.-G. Brit. 294,158, April 19, 1927. Colored cellulose deriv. compns. such as are described in Brit. 247,288 (C. A. 21, 649) or Brit. 293,485 (C. A. 23, 1749) are dissolved in glycol monoalkyl ethers or their esters or in glycol dialkyl ethers, or derivs. or mixts. of such substances. Other substances such as benzene, toluene, xylene or their mono-chloro derivs. tetrahydronaphthalene, turpentine oil, natural or artificial resins, plasticizing agents, etc., may be added.

Pyroxylin lacquer solvent. JOHN P. TRICKEY (to Quaker Oats Co.). U. S. 1,703,697, Feb. 26. Tetrahydrofurfuryl alc. is used with a resin such as shellac and with di-Bu phthalate, BuOH, EtOAc or other suitable solvents, softeners, etc.

Purifying rosin. I. GUBELMANN and C. E. HENKE (to Newport Co.). Brit. 294,526, July 25, 1927. In order to purify and decolorize rosin, it is dissolved in a vola-

tile hydrocarbon material such as petroleum naphtha, gasoline or turpentine, treated with resorcinol at an elevated temp. and then cooled, so that the resorcinol together with impurities and coloring matter seps. The resorcinol may be recovered for reuse. Various details are described.

Artificial resins. BAKELITE, G. M. B. H. Fr. 645,713, Dec. 13, 1927. Resins sol. in fatty oils are obtained by combining with heat condensation products of phenols and aldehydes with phenols contg. more than one benzene ring or with polyhydric phenols having one or more rings. Examples are given in which condensation products of phenols and aldehydes, such as "Bakelite," are heated with β -naphthol, resorcinol or diphenol with or without a catalyst such as, MnO_2 or Pb oxide. Natural resins dissolved in oils or varnishes may be added to the artificial resin. Cf. C. A. 23, 1294.

27—FATS, FATTY OILS, WAXES AND SOAPS

E. SCHERUBEL

Absorption spectra and fluorescence of fats. H. P. KAUFMANN. *Chem. Umschau Fette, Öle, Wachse Harze* 36, 34-5(1929).—The prize problem of detecting foreign fats and extd. cacao butter in pressed cacao butter, issued by the German Chocolate Mfrs. Union in January, 1927, caused K.'s work on the absorption spectra, but the latter were unsuited for solving this problem. The fluorescence spectrum yielded more success and quant. results have been obtained with the aid of Pulfrich's step-photometer; 8 references to the literature are appended. P. ESCHER

The wood-oil theory in practice. R. BURSTENBINDER. *Chem. Umschau Fette, Öle, Wachse Harze* 36, 35-8(1929).—Polymerization is only one factor in the coagulation of wood oil; reesterification and condensation are the other factors. The various colloidal phases corresponding to these factors have different phys. characteristics and solubilities. Reagents which are added to hasten or prevent coagulation of wood oil act by depolymerizing, by esterifying or by the formation of mixed glycerides. Depolymerization of the coagulated oil may also occur by reesterification, by hydrolysis or by syneresis. P. ESCHER

Determination of the emulsion-forming capacity of fats by means of a "capillary electrode." L. PRICK. *Chem. obzor.* 3, 202-3(1928).—Two Cu plates are kept apart by 2 pieces of glass of about 0.2 mm. thickness within a rubber band around the whole. The breaking of an emulsion is indicated by the glowing of an elec. lamp of 50 c. p. with a c. of 120 v. and 50 cycles passing through the electrodes and the emulsion at 40-45°. The efficiency of various methods of prepn. of emulsions and emulsifying agents is shown by different stabilities of the emulsions. JAR. KUČERA

Physical bleaching of fats for soapmaking. E. RICHARDSON. *Am. Perfumer* 23, 511-2, 571-2(1928).—A review. E. H.

New saponifier--emulsifier for fats. I. S. KIZBER. *J. Chem. Ind. (Moscow)* 5, 1176-81(1928).—When stearic acid is distd., some of the non-decompd. fats remain as a vaseline like residue which is a black, thick oil sol. in ether and petroleum ether. This residue is sulfonated thus: 100 g. of the residue is treated by a mixt. of 50 g. oleum and 50 g. H_2SO_4 (sp. gr. 1.84) which is added in small portions in the course of 20-30 mins., the temp. being kept at 38-40°, and the product is left standing overnight. The action of this emulsifier was compared with that of Twitchell's and Petrov's reagents, the latter being obtained by sulfonating certain naphthenic fractions of petroleum distillates. In equal quantities the new emulsifier does not act as efficiently as Petrov's contact catalyzer, but on operating with a larger quantity of emulsifier and water, an equal effect is obtained. The fatty acids obtained by the use of the new emulsifier are somewhat darker than usual, but the glycerol is, on the contrary, lighter. B. N.

The thiocyanate method for fats containing linolenic acid; analysis of linseed oil. X. H. P. KAUFMANN AND M. KELLER. *Z. angew. Chem.* 42, 20-3(1929).—After reviewing the methods by which the constitution of linseed oil had been detd. heretofore, K. and K. use the thiocyanate method and I no. to det. the liquid acids and Bertram's method (C. A. 21, 2391) for the satd. acids. Bertram's method showed 9-11% solid acids against 7-9% by Twitchell's lead salt alc. method. P. ESCHER

A double source of error. BRUNO REWALD. *Chem.-Ztg.* 52, 1013(1928).—The regular Soxhlet method of fat extn. from seeds and animal feeds does not obtain all of the fat, inasmuch as there are lipoids or nitrogenous substances present which contain fat that cannot be extd. The following method will ext. these substances: The material is dried and extd. in the regular manner, after which it is ground and extd. twice

again with 96% alc. followed by an extn. with a mixt. of 20 parts alc. and 80 parts benzene. The latter ext. must be taken up with ether or benzene in vegetable products to avoid the error caused by dissolved sugars. E. SCHERUBEL

International status of standardization of methods of analysis in the domain of fats and fat products. H. STADLINGER. Charlottenburg "Wissoff" session. *Chem. Umschau Fette, Oele, Wachse Harze* 36, 5-10(1929).—S. gives a summary of the extent of official methods for the analysis of fats, oils and related products in force in Germany, U. S. A., Italy, Holland, Great Britain, Russia, and Austria. There is not sufficient coöperation between analytical commissions and health authorities, custom house officials and industrial assocns. The first vol. of "Einheitsmethoden" is to be revised shortly and a 2nd vol. is to follow on waxes, Turkey-red oils, etc., after publication of the proposed methods for discussion. International standards are required for the detn. of percent of fat in oil seeds, water and total fat in crude fats; also for certain fat constns and for the analysis of glycerol. P. ESCHER

Removal of acids from oils and fatty acid distillation. Conclusion. C. H. KEUTGEN. *Seifensieder Ztg.* 56, 19-20(1929).—One unit of the Wecker App. handles 800-1000 kg. oil per hr., passing it in 5-6 min. with a residual acid content of 0.3-0.5%. The treatment precedes the ordinary treatment and recovers the bulk of free acids as a light-colored oil. P. ESCHER

Wetting agents and emulsifiers. A. NOLL. *Chem. Tech. Fabrikant* 25, 103-4 (1928); cf. C. A. 23, 1290.—A tabulated survey of the behavior of com. emulsifiers when in soln. of a solvent and mixed with water. P. ESCHER

The method for studying and identifying fats and fat mixtures. II. Turbidity point and solidification curves. B. LUSTIG AND G. BOTSTIBER. *Chem. Lab. Rudolfstiftung, Wien III. Biochem. Z.* 204, 46-61(1929); cf. C. A. 23, 1002.—A sample of fat to be analyzed is examd. in a thin layer under the microscope and under a Hanauer analysis lamp. This is compared with a sample of known fat. Only when the comparison reveals some discrepancy, pointing to an admixt. or adulteration, the unknown sample is submitted to a study of its turbidity and solidification curve whereby the fat can be identified or impurities proved. The temp. of the appearance of turbidity for various fats is given, together with many curves of solidification of many different fats. S. MORGULIS

Emulsions of fats and hydrocarbons and their industrial applications. LOUIS MEUNIER. Faculté des sciences de Lyon. *Chimie et industrie* 21, 3-19(1929). A review of their prepn. and industrial application. A. PAPINEAU-COUTURE

Luminescence in oils and fats. A. VAN RAALTE. *Nahr.-Untersuchungsanstalt, Amsterdam. Z. Untersuch. Lebensm.* 56, 195-8(1928); cf. C. A. 23, 1002.—A further discussion of the theory that the appearance of luminescence in refined oils and fats is due to *vitamin removal*. Crude oils usually lack luminescence. Vitamins may be formed in certain fats and oils by simply exposing to sunlight. The luminescence of such irradiated oils disappears. The work of Feder and Roth (C. A. 22, 1863) attributing fluorescence in crude and unpurified oils, particularly lard, to small amts. of paraffin and other impurities, is criticised. C. R. F.

Determination of the iodine number. J. J. A. WIJS. *Chimie et industrie* 20, 1043-4(1928); cf. C. A. 23, 1518.—Nielsen's statement that in carrying out the I no. detn. *via* Wijs there is substitution as well as addn. of I is refuted. Weisser and Donath's statement that it does not give theoretical results with pure unsatd. acids was due to defective technic on their part, as they prepd. their soln. with a large excess of ICl_3 . The prepn. of Wijs' soln. is described in detail. A. PAPINEAU-COUTURE

Catalytic polymerization of fatty oils. J. MARCUSSEN. *Materialprüfungsamt Berlin-Dahlem. Chem. Umschau Fette, Oele, Wachse Harze* 36, 58-9(1929).—By the use of a 5% soln. of anhyd. SnCl_4 in CS_2 , M. was able to polymerize wood oil in CS_2 soln. to a jelly at room temp. overnight; there was a 56% yield of an acetone-insol. gel. By using $\frac{1}{2}$ the quantity of SnCl_4 (0.5%) but applying heat for 1 hr. under reflux, the same jelly formed, yielding 77% of a solid acetone-insol. gel. The acid liberated from this gel is a light yellow resin of 183 acid no., 109 sapon. no., 72 I no. and a mol. wt. of 1011 (Rast's camphor method), which dropped to 590 when dried in vacuum instead of at 105° . Linseed oil could be polymerized by adding 50% anhyd. SnCl_4 directly to the oil and heating for 4 hrs. on the water bath. After removal of SnCl_4 a thick oil was obtained of 32 I no., sol. in acetone. Its acid had a mol. wt. of 430, which on purification was increased to 494. A medicinal cod-liver oil of 153 I no. also yielded with SnCl_4 a thickened oil of 41.7 I no. and a mol. wt. of 1006. P. ESCHER

Optical methods in the examination of oils. C. VAURABOURG. *Recherches in-*

ventions 9, 442-4(1928); cf. C. A. 22, 3553.—The use of Fery's refracto-dispersometer is described.

P. THOMASSET

Degree of sulfonation of soluble oils. W. HERBIG. *Melliand's Textilber.* 10, 47 (1929).—Calc'n. of the degree of sulfonation of sulfonated castor oil, etc., from the wt. of SO_3 obtained in the ordinary course of analysis is misleading. Completely sulfonated castor oil contains but 21.1% organically combined SO_3 , yet much higher values are commonly reported for com. preps. A 50% sulfonated castor oil of commerce ought to contain some 36-8% total fatty acids.

E. R. CLARK

Effect of high-frequency current on mineral and vegetable oils. VII. T. RABEK. Chem. Research Inst. (Poland). *Przemysl Chem.* 12, 240-9(1928); cf. C. A. 22, 2460.—Increased frequency of the elec. current to which a vegetable or animal oil is subjected decreases the time necessary to bring about a given change of viscosity of that oil. R. succeeded in reducing this time down to a few hrs. and in devising an app. for continuous operation by employing currents of radio frequency. Under these conditions polymerization takes place exclusively at the vapor-liquid boundary. Three designs of app. tried are described. The most successful of these effected a large surface of the liquid by producing a very thin film of it on rapidly revolving tilted shields to which it dripped from alternate shelves. A 2-kva. unit giving single-phase current of 100 v. and 7600 cycles/sec. was used. One hundred % increase in viscosity in a 10% vegetable oil has been obtained.

A. C. ZACHLIN

Fish oils. A. JULIÁ-SAURI. *Quim. ind.* 5, 257-61(1928).—Fish oils may be classified as drying oils. Paints with oils from fish of good quality resist sea air and heat. Squalene isolated from fish oils has flash pt. 195° , ignition pt. 245° , b_{10} 270° , n_{20} 1.4960, I no. 375, Engler viscosity at 25° 2.4, calorific value 10773 (petroleum = 10500-11000). Thus fish oils make good liquid fuels. The compn. of fish oils is related to ordinary oils since from the former, petroleum, gasoline and petroleum ether have been obtained. For cracking the catalyst is 50% Al_2O_3 or kaolin, or MgO (dehydrating) and 50% electrolytic Cu (dehydrogenating) at 550 - 650° . The cracked products are hydrogenated over Ni. In Diesel-Hind motors of 4 h. p. and 10 h. p., fish oil worked as well as fuel oil; rather less was consumed in relation to the power produced and the flexibility was better than with "gas-oil." Lubricating oils have a higher viscosity than fish oils. The viscosity of the latter can be increased by oxidation, volatilization or by high-tension elec. current. Fish oils are now hydrogenated, eliminating the strong odor. Their emulsifying power as soap is very great.

S. L. B. ETHERTON

Pumping, piping and heating. THOMAS ANDREWS. *Oil and Fat Ind.* 6, No. 1, 15 8, 41, 43(1929).—This is a discussion of equipment and process methods for the fatty oil plant.

E. SCHERUBEL

Virgin olive oil What does it mean? SIDNEY MUSER. *Oil and Fat Ind.* 6, No. 1, 25-6, 33(1929).—A virgin olive oil is one extd. by cold pressure from mature selected olives, without heat or treatment of any kind except filtration or settling. Flavor and color make the quality, as refined oils possess neither. The nutritional value of untreated olive oil is also enhanced by the presence of enzymes which are destroyed in heat or chemically treated oils. A virgin oil will also keep 4 times as long as a refined oil, and the presence of vitamins in the former gives it a distinct advantage.

E. SCHERUBEL

Use of the refractometric method in determination of oil in avocados. B. E. LESLEY AND A. W. CHRISTIE. *Ind. Eng. Chem., Anal. Ed.* 1, 24(1929).—Weigh 5 g. of avocado paste on a watch glass, transfer to a warm mortar with soft filter paper and pipet 5 ml. of Halowax oil into the mortar. Grind 5 min., sep. a drop of the oil mixt. and det. n , observing temp. Grind 1 min. more and repeat the n detn. Continue grinding and reading until a const. value is obtained. Correct the reading to 25° by adding 0.0004 for every degree above 25° or subtracting the same for every degree below 25° . The following formula is considered correct: $(a - 0.0032 - b)/d = c$, in which c = % oil in sample, a = n of Halowax oil at 25° , b = n of mixt. oil at 25° and d = change in n per % of oil in sample.

E. SCHERUBEL

Oil of Althea rosea Col. Its constants. J. PIERAERTS. *Mal. grasses* 20, 8363-6 (1928).—The analysis from the fresh fruits grown in Austria gives these results: Moisture 9%, ash 8.57%, dry matter 91%. Oil extd. by petroleum ether: cold 7.71%, hot 7.91%; ext. with dry ether after extn. with petroleum ether: cold 0.59%, hot 1.02%; ext. directly with ether: cold 8.25%, hot 8.41%. Consts. of oil extd. with ether: $d_{4.4}$ 0.9293, $n_D^{25.6}$ 1.4725, acid no. 69.76, expressed as oleic acid 34.88%, sapon. index 196.9, I no. 124.6, Crismer index (dissolves at ordinary temp.), Halphen reaction positive, Hehner index 94.61%; acids dried in vacuum, m. 27 - 31° ; neutralization index, 175;

sapon. index, 205.6. These consts. are very different from those obtained from fruits growing in India.

P. THOMASSET

Two new methods for determining the oil content of olives. SOCRATES A. KALOYERAS, W. V. CRUESS AND B. E. LESLY. Univ. of Cal. *J. Pharm. chim.* [viii] 8, 407-15(1928); *Fruit Products J. and Am. Vinegar Ind.* 8, No. 5, 20-2; No. 6, 27-30 (1929).—Besides describing the results of their investigations, the authors have reviewed the work of other investigators. "Two simple, rapid and reasonably accurate methods were developed." (1) The first method is based upon the n : when Halowax oil is mixed with olive oil the n of Halowax oil changes according to the amt. of olive oil dissolved. From the change in n the amt. of olive oil dissolved can be calcd. (2) The second method is based on the change in sp. gr. of Halowax oil in contact with undried olive flesh or on the change in sp. gr. of trichloroethylene in contact with a sample dried with anhyd. Na_2SO_4 . The sp. gr. method is not as accurate as the n method but is simpler and does not require such expensive app. and also no correction for the variation of sp. gr. of the different olive oils is necessary as in the n . Olive oil dissolved in Halowax oil changes in sp. gr. by an amt. which can be calcd. Complete details for these methods are given. Expts. were made to ascertain whether the oil in olives could be detd. by sapon. with strong NaOH with subsequent acidification, liberation and estn. of the fatty acids by elec. resistance.

J. A. KENNEDY

A few reactions of soy-bean oil. A. RICHARD. *Ann. fals.* 21, 579-82(1928).—Soy-bean oil is known to have been used for the adulteration of olive and peanut oils. It is best distinguished therefrom by means of its I no.; and if a given oil is known to be a peanut-soy-bean mixt. or an olive-soy-bean mixt., the approx. soy-bean oil content can be calcd. from the I no. The elaidin test (shake 10 cc. oil with 1 cc. HNO_3 and immerse in a boiling water bath) gives a yellow color with more or less complete solidification (practically complete after 24 hrs.) with olive and peanut oils, while soy bean oil turns a dark reddish brown and remains a viscous liquid without trace of solidification. Addn. of 10% soy-bean oil to olive or peanut oil is easily detected, especially by comparing with pure peanut or olive oil.

A. PAPINEAU COUTURE

Sclarea sage. GUIDO ROVESTI. *Riv. ital. essenze profumi* 10, 122-5(1928).—*Salvia sclarea* L. is a biennial. The oil from it contains linalyl acetate, salvene, pinene, sclareol, linalool, eucalyptol, borneol and resins. It has d_{20}^{20} 0.8658-0.813, $[\alpha]_D^{20}$ $-9^\circ 31'$ — $-34^\circ 43'$, n 1.4692-1.4818, acid no. 0.4-0.19, sapon. no. 98.93-163.10, sapon. no. after acetylation 169.86-218.8, free alcs. 4.34-23.48%, combined 27.20-43.12%, total 17.69-61.46%, soly. in alc. at 80° 0.8-1.1.

R. SANSONE

Composition of California walnut oil. GEORGE S. JAMIESON AND ROBERT S. MCKINNEY. *Oil and Fat Ind.* 6, No. 11, 21-3(1929).—The consts. found were d_{20}^{20} 0.9235, n_{20}^{20} 1.4751, acid value 5.11, I no. Hanus, 158.5, Wijs 161.7, sapon. no. 191.5, acetyl no. 6.09, R. M. no. 0.11, Polenske no. 0.19, % hexabromide 8.88, unsapon. 0.51%, satd. acids 5.34, unsatd. acids 89.74%, I no. of unsatd. acids 166.7. The compn. of the sample showed the following %: olein 17.6, linolein 72.8, linolein 3.2, myristin trace, palmitin 4.6, stearin 0.9, arachidin trace, unsapon. 0.5.

E. SCHERUBEL

Method for wool oil unsaponifiables. LESLIE HART. *Oil and Fat Ind.* 6, No. 11, 29(1929).—If the sample is a soap emulsion, weigh enough to give 10 cc. of unsaponified oils, ext. twice with 50 and 30 cc. of ether adding 1 to 2 cc. of 50% NaOH . Wash the ext. with 10% alc. and 2% NaOH soln. until free of soaps. Wash the combined alk. and alc. layers successively with 2 portions of ether of 50 cc. each. Combine the ether exts., evap. and weigh the residue and det. the sp. gr. If sample is a grease, weigh as above, saponify in the usual way with alc. KOH , evap. the alc., add 100 cc. H_2O and evap. to 50 cc. Cool the soln. and transfer to a separatory funnel. Rinse sapon. flask with 25 cc. ether and add to funnel. From this point proceed as in the directions for soap emulsions. A close approximation of the amt. of hydrocarbon oils is made by treating 10 cc. of the extd. oils with a mixt. of part amyl alc. and 2 parts EtOH using 40 cc. from a buret. Place the mixt. in a cylinder reading to 0.1 cc. and shake. The alcs. dissolve and the hydrocarbons sep. Note the amt. and det. sp. gr. and b. p. and calc. % by wt. based on original sample.

E. SCHERUBEL

Sesamin and sesamolin. W. ADRIANI. Dordrecht. *Z. Untersuch. Lebensm.* 56, 187-94(1928).—The constituents of sesame oil have been confused in the literature (C. A. 20, 786). Sesamin, $\text{C}_{20}\text{H}_{32}\text{O}_4$ (?) to the extent of approx. 1% was isolated from sesame oil, by crystn. from EtOH as long colorless needles, m. 122.5° , $[\alpha]_D^{20}$ $+68.23^\circ$ (CHCl_3), sparingly sol. in Et_2O or petroleum ether but readily sol. in acetone or CHCl_3 . Unlike phytosterol, it gives Bömer's reaction, a green color turning to red and finally to reddish blue when shaken with equal parts of concd. H_2SO_4 and acetic anhydride, and a cherry-red color turning to blue when a soln. in CHCl_3 is shaken with 1 drop of

concd. H_2SO_4 . It gives a negative Baudouin test. Sesamolin, $\text{C}_{20}\text{H}_{38}\text{O}_7$, m. 93.6° , $[\alpha]_D^{20} + 218.4^\circ$ (CHCl_3), and gives Baudouin's test because HCl converts it into *sesamol*, $\text{C}_7\text{H}_6\text{O}_3$, a phenolic substance, and *samin*, $\text{C}_{13}\text{H}_{14}\text{O}_5$. The sesamolin content of sesame oil is approx. 0.3%. Samin, occurred as long, colorless needles, m. 103° , $[\alpha]_D^{20} + 103^\circ$ (CHCl_3), and failed to give the Baudouin reaction with furfuraldehyde and HCl . Samin is isolated here for the first time.

C. R. F.

Some Mackey tests on cottonseed oil. HERMAN ASPEGREN. *Oil and Fat Ind.* 6, No. 1, 19–24 (1929).—A no. of detns. were made to show how the changes in cottonseed oil during hydrogenation would influence the Mackey test. It was shown that the heating curves gradually flatten out and the tendency to heat had nearly disappeared when the process had advanced so far as to reduce the linoleic acid content to 16%. With linoleic acid gone, but with 83% of isoleic and oleic acid, the fat did not show any tendency to spontaneous heating during the Mackey test. Other tests indicate that the same percent of glycerides of linoleic acid which have not been exposed to the hydrogenation process would have a tendency to develop a steeper heat curve than the same percent of these glycerides which have been exposed to the hydrogenation process. Crude cottonseed oil showed practically no tendency toward heating during the Mackey test. Possibly impurities may have a retarding catalytic influence. Heating curves of refined cottonseed, corn, sesame, olive, peanut and coconut oil indicate that with decreased percent of linoleic acid, the Mackey test heating curves flatten, and evidently are principally affected by the percent of linoleic acid and to a much less extent by the percent of oleic acid.

E. SCHERUBEL

Oil from the seeds of *Adenanthera pavonina*. A source of lignoceric acid. S. M. MUDHIDRI, P. RAMASWAMI AYYAR AND H. E. WATSON. *J. Indian Inst. Sci.* 11A, Pt. 14, 173–80 (1928).—*Adenanthera pavonina* is a moderate-sized deciduous tree belonging to the order Leguminosae and is found in the Eastern sub-Himalayan tract, the Western Ghats, Sylhet, the Andamans and Burma. The kernel and husks are nearly equal in wt and difficult to sep. The husk yields a trace of oil, while the whole seed yields 14% and the kernel 28%. The av. wt of the seed is 0.24 g. Consts. of the oil are $d_{15.6}^{20} 0.9168$, $n_D^{20} 1.4570$, acid value 0.56. I no. 87.9, sapon. no. 181.4, unsapon. 1.4%, viscosity (Redwood) 128 sec., acetyl no. 3.4, Reichert-Polenske no. 122, Polenske no. 0.24. Consts. of the mixed fatty acids: titer 58.4° , $n_D^{20} 1.4541$, mean mol. wt. 301, unsatd. acids 64%, mean mol. wt. of unsatd. acids 286, of satd. acids 36%, mean mol. wt. of satd. acids 328, I no. of unsatd. acids 111, Helmer no. 95.5. The compn. of the acids is: myristic 0.4, palmitic 9.0, stearic 1.1, lignoceric 25.5, oleic 49.3 and linoleic 14.7%. The amt. of lignoceric acid is greater than any recorded in an oil. E. S.

Oil seeds from British Guiana. ANON. *Bull. Imp. Inst.* 26, 411–6 (1928).—Crabwood (*Carapa guianensis*) oil prepd. in Brit. Guiana and extd. from the kernels with petr. ether at the Imp. Inst. had the following consts.: $d_{15}^{100} 0.8689$, 0.8572 ; $n_{40} 1.4590$, 1.4560 ; solidifying pt. of fatty acids, 37.8° , 35.8° ; acid value, 36.9, 75.8; sapon. value, 198.5, 197.4; I no. (Hübl, 17 hrs.), 57.3%, 64.5%; unsaponifiable matter, 1.1%, 0.7%, resp.; these are normal values. Oil extd. with petroleic ether from the pericarp and from the kernels of Awarra palm (*Astrocaryum jauari*, Mart.) fruit had the following consts.: $d_{15}^{100} 0.8573$, 0.8660 ; m. p., —, 30.8° ; $n_{40} 1.458$, 1.4505 ; acid value, 38.4, 0.4; sapon. value, 195.8, 241.9; I no. (Hübl, 17 hrs.), 68.0, 14.6%; unsaponifiable matter, 0.5, 0.5%; sol. volatile acids, 0.4, 2.4; insol. volatile acid, 0.2, 6.8; solidifying pt. of fatty acids, 36.7° , 27.0° . The consts. of the kernel oil agree with previously published values, except that the solidifying pt. of the fatty acids is higher (27.0° instead of 23.5°). The oil from the pericarp would be suitable for the same purposes as palm oil from the African oil palm.

A. PAPINEAU-COUTURE

A new oil seed from Brazil. ANON. *Bull. Imp. Inst.* 26, 416–8 (1928).—On extrn. with petr. ether the kernels of nuts of *Joannesia heveoides* from Brazil (known locally as "castanha de arara") yielded 57.3% (61.0% on dry basis) of oil having the following consts.: $d_{15}^{16} 0.9239$, $n_D^{20} 1.467$, acid value 2.1, sapon. value 188.5, I no. (Hübl, 17 hrs.) 129.8%, unsaponifiable matter 0.48%. The residual meal has a faintly bitter taste and an odor somewhat resembling that of castor oil. It contained: H_2O 8.0, crude proteins 47.4, fat 0.7, N-free ext. 25.1, crude fiber 6.5, ash 12.3%, nutrient ratio 1:0.56, food units 145; it contained a substance or substances of an alkaloidal nature. The oil is suitable for soap-making; it has semi-drying properties and might possibly be of use, after "boiling," for paint manuf. in admixt. with linseed oil. Physiol. tests would be necessary before pronouncing on the suitability of the oil and meal for edible purposes.

A. PAPINEAU-COUTURE

Jute seeds—Corchorus capsularis. II. Composition of oil Corchorus. NIRMAL-KUMAR SEN. *Dacca Univ. J. Indian Chem. Soc.* 5, 759-67(1928); cf. *C. A.* 21, 3647.—Refined jute-seed oil had the following characteristics: d_{20}^4 0.923, n_D^{20} 1.4615, solidifying point -20° , I value (Hübl's) 102.6, sapon. value 184.6, acid value 1.5, Ac value 27.3, Reichert-Meissl value 0.16, unsapon. matter 2.25%, sol. acids (% of $C_{18}H_{34}O_2$) 0.32, insol. acids 94.1%, glycerol 9.2%. The oil contains 39.18% glycerides of oleic acid, 44.63% glycerides of linolic acid, 0.169% of "crude arachidic acid," and small quantities of palmitic and stearic acids. From the unsapon. portion of the oil a very small quantity (0.6145%) of a phytosterol was obtained.

LOUISE KELLEY

Soaps from organic bases. R. B. TRUSLER. *Soap* 4, No. 6, 33-7(1929); cf. *C. A.* 23, 1004.—There are 3 ethanolamines, mono-, di- and tri-, from which soaps are made. They are synthesized from NH_3 and differ slightly in their phys. and chem. properties. They are miscible in all proportions with H_2O , alcs., acetone and its homologs, glycerol, glycol, ethylene and propylene chlorohydrin and many oxygenated org. compds. Exceptions are Et_2O and some of the aldehydes in which ethanolamines are scarcely sol. One mol. wt. of any of these is equiv. to 1 mol. wt. of $NaOH$ in combining with an acid. For technical purposes a mixt. consisting of 75 to 80% tri-, 20 to 25% of di- and 0 to 5% of monoethanolamine has a price advantage and is offered under the name of Enthanolamine. In order to prep. any of the soaps it is best to det. the basicity by titration in H_2O against a standard acid and then use weighed amts. of both ingredients. The liquid fatty acids such as oleic best serve the purpose. No external heat is required. To combine solid fatty acids with ethanolamines 2 procedures are available: The fatty acid may be heated to 60° and the correct amt. of ethanolamine stirred in; or the fatty acid may be dissolved in denatured alc. and the ethanolamine stirred in. The soap is recovered by evapg. the solvent.

E. SCHERUBEL

Manufacture of dry and powdered soaps. PEDRO BOSCH. *Quim. ind.* 5, 288-9 (1928).—Soap powders contain some 5 to 50% fatty acid, most powders being mixtures of soap and crystals of soda. Some may contain Na silicate, phosphate and decolorants. Domestic soap powders are never perfumed and but rarely colored, although a little ultramarine blue may be added so that the washed articles may appear whiter. Colophony is never used in these soaps. The color and compn. of the soaps should be const. All powders should be as fine as possible upon evaporation, so as to avoid agglomeration. The addn. of 0.25% $NaHCO_3$ helps in this respect. B. gives 7 methods for the manuf. of dry soaps and makes sundry observations as their application. He concludes with general considerations upon trituration and incorporating plant employed in these processes.

S. L. B. ETHERTON

The use of rosin in soap making. R. BREDON. *Bull. inst. pin* No. 56, 42-4(Jan., 1929).—A discussion of the precautions which must be taken to obtain a high grade product in making soaps contg. up to 15-20% rosin.

A. PAPINEAU-COUTURE

Rosin soaps. BIGORIE. *Bull. inst. pin* No. 56, 40-1(Jan. 1929).—Brief outline of the merits of properly prepd. rosin soaps and of their uses.

A. P. C.

The salt-rubin number of soaps. L. ZAKARIAS. *Z. phys. chem. Seifenforsch.* 2, 4(1929).—Beyrodt and Zakarias' salt-rubin method for soaps did not respond with a color change when fresh Congo rubin "Agfa" was employed; the published results had been obtained with a 10-yr.-old dye.

P. ESCHER

Determination of the detergent value of washing compounds. L. E. LEDERER. *Seifensieder-Ztg.* 56, 33(1929).—In Löffl's equation (*C. A.* 23, 1519) for the detergent value of soaps cond. (mho) cannot be added to surface tension (dyne/cm), etc., nor are cond., inner friction and lathering no. proportional or reciprocal to surface tension. In order to det. the cleansing value of a soap, something must be cleaned with the soap; the proposed method of the A. O. C. A. in the U. S. A. are more suitable from that viewpoint than Löffl's proposal.

P. ESCHER

Determination of the detergent value of washing compounds. K. LÖFFL. *Seifensieder-Ztg.* 56, 49(1929).—An answer to Lederer's criticism (preceding abstr.) The meaning of "washing compds." must be defined, and the components that make up the cleansing effect and the degree of fiber damage must be detd., and each given its proper factor for calcn.; an evaluation is then possible by comparing detergent value with price of soap.

P. ESCHER

Discoloration and rancidity. O. F. SREVER. *Am. Perfumer* 23, 771, 775(1929).—Milled soaps are exposed to all possible reactions and in consequence of the presence of foreign substances there may result ill-smelling reactions. These may be due to hydrolytically split off alkali or acid soaps; and this does not preclude the passing into acid combinations of the hydrolytically sepd. alkali with certain perfumes. The greater the amts. of alkali and fatty acid split off by hydrolysis, the more sensitive become the

toilet soaps in the presence of the various admixts. as well as contact with metals and air.

Some general considerations on oil soaps. S. J. MILLER. *Am. Perfumer* 23, 337-8, 453-4, 457, 631-3 (1928).

Evaluation of washing compounds by means of surface tension. BRUNO WALTHER. *Z. angew. Chem.* 41, 1083-9 (1928).—By means of the Traube stalagmometer, which passed through a water bath, the no. of drops were counted with soap solns. of different concns. and temps. delivered in a given time, and by means of Traube's stalagmometer formula these values were converted into ergs surface tension. Analytical data of the fats and soaps are given, together with the stalagmometer measurements. The soaps which contain only one kind of oil were made in the lab.

Surface tension in ergs of soap solns. contg. 0.3% fatty acids:									
Temp.	Lux	Sunlight	Na oleate	Thompson	Persil	Rosin soap	Palm kernel	Palm oil	Coco-nut

P. ESCHER

Bromometric examination of fats (ANDRISKA) 17. Use of enzymes for degreasing (DELROISSE) 25. Chemical treatment of trade waste. V. Waste from wool washing (SNELL) 14. Some special constituents in the soy bean (MURAMATSU) 11D. The anhydride of abietic acid (NAGEL) 10. Dispersing agents for use in dyeing cellulose esters and for other purposes [antiseptic soaps] (Brit. pat. 295,024) 25. Absorption tower suitable for treating oils (U. S. pat. 1,703,571) 1. Soaps containing sorbitol and its derivatives (Brit. pat. 294,130) 17.

Ubbelohde's *Handbuch der Chemie und Technologie der Öle und Fette*. Leipzig: S Hirzel. Edited by Dr Hans Heller. 791 pp. M. 75.

Fats and oils. KARL F. WILHELM. Fr. 33,425, May 3, 1927. Addn. to 577,037. Fatty acids, resins and bitter and mucilaginous substance are extd. from fats and oils by treating with equal parts of a solvent for the fatty acids and a solvent for the oils, which solvents do not mix, such as alc. and C_2H_5Cl , CH_2Cl_2 , benzine or the like. About 1% of Glauber salts may be added.

Oils and fats. I. G. FARBENIND. A.-G. Fr. 645,497, Dec. 9, 1927. C_2H_5Cl with or without another solvent is used for extg. oil and fats of vegetable or animal origin.

Sulfonated fatty acids. I. G. FARBENIND. A.-G. Fr. 645,819, Dec. 16, 1927. Fatty acids of suint are made sol. in water by mixing them with PhOH and treating with H_2SO_4 or $ClSO_3H$.

Sulfonating oils. ERBA A.-G. Brit. 294,621, July 28, 1927. Colorless products are obtained by the sulfonation of castor oil or a similar fatty oil in the presence of reducing bleaching agents (such as sulfites, hyposulfites or the compds. of CH_2O with CH_2O with alkali hyposulfite or alkali sulfoxylates) or of oxidizing bleaching agents (such as peroxides, per-acids or per-salts) in a quantity in excess of that required for catalyzing the sulfonation. Also, the oil used may be preliminarily bleached or the sulfonated product may be subjected to an after-bleaching. Cf. C. A. 23, 1520.

Mineral oil sulfonates. CHARLES FISCHER, JR., and WARREN T. REDDISH (to Twitchell Process Co.). U. S. 1,703,838, Feb. 26. "Mahogany soap" is mixed with an aq. alc. solvent of over 75% strength which is supersatd. with Na_2CO_3 , in order to sep. oil from sulfonated components.

Washing powdered material. EMILIO SILVANO and VINCENZO L. CERRI. Fr. 645,710, Dec. 8, 1927. See Brit. 282,446 (C. A. 22, 3795).

Soap-like products. I. G. FARBENIND. A.-G. Fr. 33,435, May 6, 1927. Addn. to 619,650. Products whose aq. solns. have wetting cleansing and emulsifying proper-

ties in acid baths or in hard water consist of a sulfonic acid or its salt and materials having soap-like properties in a colloidal state. An org. solvent may be added. Fatty acids, resins, paraffin wax, naphthenic acids, decompn. products of wool, etc., may be used with substituted aromatic sulfonic acids. In an example, olein in MeOH is mixed with isopropyl-naphthalenesulfonic acid or its Na salt, and a soln. in water may be used as a substitute for soap. Na butyl-naphthalenesulfonate is dissolved in water and a soln. of an oil formed by the hydrogenation of oxides of C is added and an artificial resin produced by heating cyclohexanone with an alkali metal methylate.

Toilet and detergent composition. BORIS N. SOKOLOFF. U. S. 1,703,602, Feb. 26. A solid, stable homogeneous detergent compn. suitable for use on the skin or textile fabrics comprises soap 12, borax 2, petroleum jelly 5 and water 20 parts.

Penetrometer suitable for use with soaps, cup greases, etc. WINFRED R. GODDARD and CHARLES K. HEWES. U. S. 1,703,270, Feb. 26. Structural features are specified of a device comprising a freely falling tapered and pointed body.

28—SUGAR, STARCH AND GUMS

F. W. ZERBAN

A study of the refining qualities of Philippine raw sugar. PEDRO SENGSON. *Sugar News* 9, 807-11(1928).—The study was made in 6 different Negros centrals and covers a period of 4 years beginning with the 1924-1925 crop. The samples used in the tests represent a total of 360,874 tons of sugar a yr. Data for each yr. and graphs are given from which S. makes the following conclusions: (1) the polarization remained practically the same; (2) the moisture content of sugar was reduced considerably, and its keeping qualities were improved; (3) the ash remained practically the same; (4) there was no appreciable change in filtration rate, although there was a marked increase in clarity; (5) the color of the original sugar was reduced, but the color within the crystals was increased; (6) the amt. of insol. matter was diminished; (7) the size of grain was increased considerably. S. recommends: (1) that no attempt should be made to raise polarization above 97° unless the refiners would be willing to pay for polarization above this; (2) that the % ash should be kept as low as possible; (3) that sugar colloids should be further eliminated by well controlled clarification and a system of sugar boiling that will minimize the circulation of the impurities within the boiling house; (4) that low-grade sugar should be used for "seed," and boiling should not be carried out at too high a temp.; (5) that insol. matter may further be reduced by straining the juices and sirups through fine-mesh Monel metal; (6) and that no effort should be made to make sugar of "large" grains as this kind will delay the entire factory operation.

V. G. LAVA

Technical method of using the mercury arc to obtain data at wave length 560 mμ in the spectrophotometric analysis of sugar products. H. H. PETERS and F. P. PHELPS. *Bur. Standards J. Research* 2, 335-42(1929).—Previous investigations (C. A. 21, 2813) showed that the detn. of the sp. absorptive index at wave length 560 mμ affords a measure of the quantity of coloring matter in sugar products. Ordinarily a spectrometer is required to produce monochromatic light of this wave length. But instead of this a Hg vapor lamp may be used, and measurements of transmittancy made at wave lengths 546 and 578 mμ, spectrally purified by means of special filters. Then the sp. absorptive index at 560 mμ may be calcd. within 1% of its actual value by deducting 48% of the difference between the sp. absorptive indices at 546 and 578 mμ from that at 546 mμ. This rule holds for all the numerous cane products and also for the few beet products examd., but only under the condition that asbestos-filtered solns. are used.

F. W. ZERBAN

The verification of the 100° point of the Ventzke sugar scale. Introduction. C. A. BROWNE. *Bur. of Chemistry and Soils. J. Assoc. Official Agr. Chem.* 12, 100-7 (1929).—A brief outline of the reasons leading to a study of the problem by the Bur. of Chemistry and Soils and the N. Y. Sugar Trade Lab., under the auspices of the Assoc. of Official Agr. Chem. I. R. T. BALCH and H. C. HILL. *Bur. of Chemistry and Soils. Ibid* 108-15.—The polarization of a soln. contg. 26 g. of sucrose per 100 cc. at 20° was found to be 99.907° Ventzke, which agrees well with the value detd. by Bates and Jackson of the U. S. Bur. of Standards (1916), and which disagrees with the values found by European investigators. The accuracy of this value was substantiated by detg. the polarization of a soln. contg. 26.026 g. per 100 cc. at 20°. The av. value for the new normal wt. was found to be 100.008° Ventzke. This soln. contained 23.724%

sucrose and had d. 1.09965. II. F. W. ZERBAN, C. A. GAMBLE AND G. H. HARDIN. N. Y. Sugar Trade Lab. *Ibid* 115-20.—The av. saccharimetric reading for the normal wt. (26 g. per 100 cc.) of sucrose (after correcting for H₂O, ash and reducing sugar) was found to be 99.912° Ventzke, old scale, which checks the results of Balch and Hill within 0.007% and those of Bates and Jackson within 0.017°. The true saccharimetric value of the normal wt. of soln. of sucrose should be very close to the av. value of 99.904%, which may be rounded off to 99.90° Ventzke, Herzfeld-Schonrock scale.

A. PAPINEAU-COUTURE

Studies of foaming during saturation. VI. STANĚK AND J. VONDRÁK. *Listy Cukrovar.* 47, 17-32(1928).—Eleven liquors from sugar mills and some which had not been treated with lime were observed. A vertical glass tube 80 × 5 cm. has a steel capillary tube in the lower end through which air satd. with CO₂ (28%) was blown at the rate of 47 l. per hr. The juices (250 cc.) were mixed at 85° with 25 cc. of a 2% CaO soln. After 5 mins. of clarifying the mixt. was poured into the tube. The foam reached a max. height in 1-3 mins.; the whole detn. required less than 5 mins. The max. is reached at the beginning of a run, agreeing with industrial observation; only one max. is reached during a run regardless of the length of run. A result of 20 runs shows a reproducibility of 23-26 cm. (94-106%) foam. The foaming increased with the concn. of the juices, a lowered temp. (85°) of clarifying, a decrease in the concn. of the CO₂ in the bubbled air, decreased rate of flow of the gas. The factors: satn. temp., amt. of CaO and time of clarification have an effect, but the various juices responded to them individually. A small quantity of fat had the most effect (0.05 mg. to 250 cc. of juice); an excess of fat increased the foaming above the min. The following order existed for various antifoaming agents: rape oil (column attained 49% of the height of the same untreated juice), mineral oil 53%, ricin 53%, lanolin 53%, olein 73% and hexalin 100% (no effect); the order was different for different juices. Rape oil was applied as a 0.1-5% emulsion in a 2% soap soln. and gives the same effect as the free oil. The advantage is in economizing the rape oil. Further industrial observations are promised.

FRANK MARESH

Illumination of evaporating bodies and the observation of the cloudiness of juices during their preparation. VIKTOR KORAN. *Listy Cukrovar.* 47, 240-1(1929).—K. passes a beam of light across a tank and observes the intensity of this beam through a window at right angles to the course of the beam. The intensity of the light beam gives some knowledge as to the opacity of the soln. being evapd. in a sugar mill. F. M.

Mechanical cane unloaders, system Schippers-Cordesius. W. W. SCHIPPERS. *Arch. Suikerind.* 36, II, 1097-1102(1928); cf. *C. A.* 22, 181. —In comparison with other mech. cane unloaders, the cane dumper should be preferred. This system gives more capacity, and is lower in initial cost and in upkeep than other systems. P. R. P.

Separate grinding of each variety of cane. TH. J. D. ERLER. *Arch. Suikerind.* 36, II, 815-35, 843-74, 888-904(1928). To get a better insight into the real results of the mill work it is recommended to grind the cane of different varieties separately. At Ketegan this was done during the crop of 1925 and 1926 with satisfactory results. The sources of error in the different detns. are discussed. The av. error for sucrose % cane is 0.056, and for fiber % cane 0.24. The results of the expts. are given in tables and graphs. It is pointed out that mill results calcd. on sucrose figures and on Brix figures are of the same order. The figure for sucrose extn. % cane is of no value for judging mill work. The relation between fiber % cane and lost juice % cane was the same as that calcd. by Bolk. The relation between yield and yield factor is due to the sucrose lost in bagasse % cane, influenced by the fiber % cane. P. R. P.

Comparisons of (cane variety) H-109 with Luzon White under different conditions in the Laguna-Cavite district. MANUEL L. ROXAS. *Sugar News* 9, 829-33(1928).—The Luzon White (native) is more resistant to drought than H-109. This is to be expected as the selection of H-109 was made in irrigated districts. If H-109 could be made to give as good a stand as Luzon White, its optimum no. of stools per hectare would be around 23,000. V. G. LAVA

Some remarks on the sampling of cane for the mill control, referring to the paper: "Determination of available sugar in cane," by C. Sylmans. TH. J. D. ERLER. *Arch. Suikerind.* 36, II, 1045-61(1928). —Discussing the paper of Sylmans (*C. A.* 22, 2677) E. calls attention to the fact that it is almost impossible to det. the unknown losses from the field to the mill and from the mill to the juice weighing tanks separately, while for detn. of the last-mentioned loss the taking of an av. sample of the cane at the moment of grinding is required. Therefore, it is suggested to det. the total loss from the field to the juice weighing tanks by taking a sample of the cane in the field. A method for cane sampling in the field is described. P. R. P.

The glucose content of cane molasses. H. S. WATERMAN AND J. A. V. D. LINDE. *Arch. Suikerind.* 36, II, 1151-5(1928).—A no. of final molasses from Java mills using different clarification systems were analyzed, and in comparison with them a no. of European molasses. The results show that the Java molasses contain from 7 to 8% glucose and European molasses 1%. The formation of glucose is favored by high temp. and high p_H . It will be investigated if the original cane juice in Java contains glucose.

P. R. P.

The control of yield, based on purification, and on the purity of the molasses. RENÉ GILLET. *Sucr. Belge* 48, 1-8(1928).—The interpretation of purity figures in the control of clarification of juice and of exhaustion of molasses is thoroughly reviewed.

E. A. FIEGHR

The results of the Djombang method at Ketegan. TH. J. D. ERLEE. *Arch. Suikerind.* 36, II, 1155-64(1928).—A survey is given of the results with the Djombang method at Ketegan during 3 yrs. It is pointed out that this is the only method which gives accurate results for the yield of every field separately, without the use of the yield factor and the wt. of the cane. The relative value of different varieties can also be detd. by the method and several practical questions may be resolved. The method showed that the fiber of lodged cane is not necessarily lower than the fiber of standing cane.

P. R. P.

Determining the value of beet seed. K. DOMBROWSKI. *Bull. Assoc. Polish Beet Sugar Manufacturers* No. 1521, 897-904(1927); *Facts About Sugar* 23, 400-2(1928); cf. *C. A.* 21, 3478.—A formula has been derived for estg. the cost of sugar manuf. in relation to the sugar content of beets. With the extn. ratio and the tonnage const. an increase of 0.10% in the sugar content of the beets would decrease the cost of sugar by 6 cents a quintal at the Wlostow factory in Poland. The same decrease in cost of sugar would be obtained by increasing the yield of beets by 3.72% equiv. to 186.7 quintals a hectare or 600 lbs. an acre, keeping the sugar content of the beets and the extn. ratio const. Applying this computation to the results obtained in the competitive trials of varieties of beets in 1926 by the Assocn. of Polish Beet Sugar Mfrs. indicates that a factory using the variety giving the highest yield of beets would lose 27 cents a bag (of 100 lbs.) compared with what it would have made by using the variety with the highest sugar content. It is concluded that the quality of beet seed should be detd. on the basis of the cost of producing sugar from it; and that variety trial plots should be planted at every factory and the results made public for the guidance of seed producer, grower, manufacturer and all others concerned.

M. J. PROFFITT

The commercial value of sugar beet seed. E. ZALESKI AND J. NEYMAN. *Facts About Sugar* 23, 1144-6(1928); cf. *C. A.* 21, 3478.—Dombrowski's formula (cf. preceding abstr.) is considered faulty and a formula (still not perfect) is worked out for similar use. It takes into account those considerations not taken care of by D.'s formula.

M. J. PROFFITT

The Komers-Cuker process at Tavikovice and at Krumsin, its value for small agricultural establishments and for large factories. ARNOLD KUHNER. *Oesterr. Chem.-Ztg.* 32, 14-5(1929); cf. *C. A.* 22, 2075, 4269.—This process can be worked on a small scale and, with its saving in freight charges and other items, makes the beet farmer independent of the central factory. It makes it possible to produce one grade of sugar and a high-grade stock feed, without making molasses; no lime kiln is needed. The diffusion battery consists of 5 open vessels with agitators, and with transport helixes between them. They are arranged so that the cosettes come in contact with air as much as possible. The sirups are returned to the 2nd diffuser. The diffusion juice is limed with 0.25% Ca(OH)_2 , and a little acid phosphate is added. The ppt. is removed in Sharples centrifuges. The juice is then carbonated down to 0.01% CaO , with CO_2 produced from coke, and sent through presses. The thin juice is evapd., generally in vacuum effects, or in large factories perhaps by pressure evapn. The thick juice is filtered and then boiled to grain, the run-offs being drawn into the pan, occasionally a low-grade boiling may be necessary in large factories. The beet wash waters may be returned when water is scarce. It is claimed that the total sugar losses are smaller than in the usual process; part of the sugar gained goes into the raw sugar and part into the dried chips. The cost of labor, materials and operation is greatly reduced, and technical supervision is reduced to a min. There are no waste waters to pollute streams.

F. W. ZERBAN

Factory control of sugar entering in beets compared to sugar in diffusion juice plus diffusion losses. J. ZAMARON. *Bull. assoc. chim. suc. dist.* 45, 580-2(1928). The vol. of juice as measured on leaving the diffusion battery is slightly too great because of suspended gas bubbles and high temp. A table is given to convert the observed

vols. to true vols. at lower temps. Vol. corrections based on the water table give the amt. of sugar in diffusion juice plus sugar in losses to be greater than sugar in beets entering the factory. The table was worked out experimentally. Calcns. by this table gave the amt. of sugar in diffusion juice plus the sugar in diffusion losses to be slightly less than the amt. of sugar in beets entering the factory. This is in accord with the view that there is a slight destruction of sugar in the battery. E. A. F.

The saturation of sugar-lime solutions. III. A. H. W. ATEN, P. J. H. VAN GINNEKEN AND E. VERWEY. *Rec. trav. chim.* 48, 93-115(1929); cf. C. A. 22, 2867.—Solns. which are about 0.35 *M* in sucrose and *N* in CaO absorb CO₂ rapidly. With a ratio (*R*) between CO₂ and CaO of 0.5 to 0.6, the ppt. contains CaCO₃·Ca(OH)₂ and sucrose. The ratio between lime and sucrose in these solns. is approx. const., around 1.5; the ratio between CaCO₃ and CaO increases with *R*, and at const. *R* with increasing sucrose concn. When *R* is smaller than 0.5, no ppt. appears. If the sucrose concn. is 0.35 *M*, but that of CaO is smaller than *N*, the value of *R* which produces a ppt. becomes smaller, and the ppt. is less basic. As the CaO concn. is further diminished, the solns. behave more and more like sucrose-free solns. If the sucrose concn. is increased at const. CaO concn. a smaller quantity of CO₂ is required to produce a ppt. At 90° those solns. which do not give a ppt. at room temp. produce a basic ppt. which redissolves on cooling. Solns. 0.7 *M* in sucrose and 1.7 *N* in CaO give besides the ppt. already mentioned another ppt. at *R* = 0.1 to 0.3 which dissolves upon the further addn. of CO₂. In the latter ppt. the ratio between total lime and sucrose is 2; the ratio between total lime and CaO varies from 6:1 to 6:2. At 90° this ppt. dissolves. With solns. molar in sucrose and 2.3 *N* in CaO, a ppt. is obtained only if *R* is very high; with *R* around 0.77, the soln. gels; with *R* = 0.67 the soln. remains liquid at room temp. but gels at higher temps. The viscosity-temp. curve shows a decided min. The basic ppt. mentioned at the beginning changes upon shaking to CaCO₃·6H₂O, while the free lime and a part of the CaCO₃ go into soln; upon standing this CaCO₃ ppts. again slowly until the soln. is satd. in CaCO₃·6H₂O. The soln. still contains a considerable quantity of CaCO₃ which is the greater, the greater the concn. of CaO and the smaller the sucrose concn. The conversion of the basic ppt. into CaCO₃·6H₂O is reversed by increasing the temp. The elec. cond. of the solns. diminishes sharply when CO₂ is absorbed by them, no matter whether a ppt. is formed or not. This fall in the cond. is much greater than could be caused by the formation of undissocd. CaCO₃. It follows that free lime disappears. The same conclusion is reached by *p_H* detns. When the CaCO₃ crystallizes out the lime is liberated again, and the cond. rises. The cond. permits an approx. calcn. of the compn. of the complexes present in the soln. This varies from 2CaCO₃·Ca(OH)₂ to CaCO₃·2Ca(OH)₂, and perhaps within even wider limits. A part of the OH is substituted by sucrose. When CaCO₃·6H₂O crystallizes out, 1CaO is liberated for every 3CaCO₃. The presence of the complexes was confirmed by ultrafiltration expts. and by ultramicroscopic observations. F. W. ZERBAN

The question of what manner of liming is to be preferred. H. CLAASSEN. *Z. Ver. deut. Zuckerind.* 78, 543-8(1928).—In the liming of beet juices, whether the use of dry lime or of milk of lime is to be preferred is still an open question. Claims for both methods are equally pointed. Lab. expts. cannot be carried out to reproduce factory conditions, as bulk plays an important role. Therefore, C. examd. the molasses. The properties of molasses depend on the nature of the juice, on the mode of extn., and on the precautions in treating the juice. By examg. a large no. of molasses samples from factories not too far apart, useful comparative figures can be obtained. Results calcd. on the basis of 100 parts of non-sugars show (1) that as regards ash and org. non-sugars, no essential difference exists between molasses obtained from factories using the dry lime process or the milk of lime process for liming the beet juice; (2) that a very noticeable difference exists in the lime salts, total N, and color, and for these 3 figures, to the disadvantage of the milk of lime process. The color figures are especially striking. The conclusion is that in the dry liming process, neither is more sugar destroyed, nor are the juices more highly colored than in the milk of lime process. On the contrary the dry liming method seems to favor the production of light-colored juices, if reasonable contrivances are provided. E. A. FIEGER

Inversion of sucrose in beet-house sirups. R. J. BROWN AND H. W. DAHLBERG. *Ind. Eng. Chem.* 21, 282-5(1929).—The purpose of this study was to det. the approx. rate of sucrose destruction under factory conditions. Because of the location of the lab. at high altitude, invert sugar was detd. by the method of Quisumbing and Thomas (C. A. 16, 37), in which a temp. of 80° is used. The sirup soln. was clarified with neutral Pb(AcO)₂ soln., and then decalc'd with a mixt. of Na oxalate and Na₂HPO₄ (Cook and McAllep, *Facts about Sugar* 23, 280(1928)). Summary of conclusions: "The in-

vert sugar content of low-purity beet products cannot be taken as a measure of previous inversion of sucrose, because of the destruction of invert sugar in such products. In the range of 6 to 9 p_H the rate of destruction of invert sugar depends on the concn. of impurities, the p_H showing no measurable effect. Decreasing the p_H of the sirup from 8 to 6 increased the rate of loss of sucrose about 10 times. Decreasing the purity from 100 to 60% decreased the rate of loss of sucrose about 40%. A 10° temp. rise increased the rate from 2 to 3 times. Variation in concn. of solns., in the range of 10 to 80% dry substance, produced no marked effect on the rate. The rate of loss of sucrose in beet sirups from different sources was found to be const. under const. conditions. The rate of loss of sucrose in sirups of 90% purity at 6 p_H and 80% dry substance heated at 80° was almost double that calcd. by Spengler and Toedt on the basis of the inversion const. of sucrose in HCl found by Jackson and Gillis." F. W. ZERBAN

Analysis of maple products. X. Study and modification of the Canadian lead method. D. E. FOWLER AND J. F. SNELL. McDonald Coll., McGill Univ. Toronto. *Ind. Eng. Chem., Anal. Ed.* 1, 8-12(1929); cf. C. A. 21, 1204.—Using the Assoc. Official Agr. Chem. method as a basis for the detn. of Pb value, numerous modifications were studied with the object of detg. the cause of the inconsistent results often obtained by the use of this technic. Large exptl errors resulted from the formation of fissures in the ppt. on the filter and consequent irregularities in the solvent action of hot wash H_2O . If the washing is done by centrifuge and decantation, this error is eliminated. The quantity of ppt. increased with the temp. at which pptn occurred. The Pb ppt. is sol. in an excess of the basic acetate soln. and in sucrose soln. as well. Modifications of the existing method including the use of cold wash H_2O are proposed. XI. *Ibid* 12-3.—Analysis of 3 maple sirup samples showed that the total Pb content varies inversely as the Canadian Pb value. The increase varied from 72.64 to 67.58%. The malic acid as detd. polarimetrically in a composite ppt. from 20 sirups constitutes 97% of the acids liberated by H_2S . The ppts. contained from 11.1 to 12.2% C and 1.46 to 1.15% H, i. e., substances much more carbonaceous than Pb malate are present. The flavoring and coloring matters appear to be pptd. by basic acetate. C. R. F.

The installation of electrical machinery in sugar mills from the safety standpoint. G. JOBSIS. *Arch. Suikerind.* 36, II, 963-75, 989-1008, 1063-75, 1085-97, 1105-16, 1131-9(1928). P. R. P.

Studies on filter cloths in sugar mills. K. ŠANDERA. Exptl. Inst. Czechoslovakian Sugar Ind. Prague. *Listy Cukrovar.* 47, 227-33(1929).—A statistical study of filter cloth based on reports from 64 sugar mills. The lasting quality of filter cloths is not affected by high temp. or continuous usage. Most solns. are used at 70-95° and rarely below 60°. Satd. solns. have no definite effect upon the economy of satn. The filtering area which is at the disposal of filtering juices after first satn. is not a governing factor for economical filtration and ranges from 25 to 35 sq. m. per 1,000 kg. of beets. The amt. of CaO added showed no connection with economic filtration. The time for changing filter cloths varied from 3 to 39 days. Thirty-six % of the mills changed the cloths before 8 days of use; 39% changed them after 8-19 days, and 25% used them for more than 19 days. Fourteen % of the mills used the cloths for over a month (30-39 days). The reasons for frequent changing of cloths were given as: decreased flow, cloudy filtrate, tears and disintegration. The clogging of filter cloth was most frequently due to the previous treatments and processes as: oversatn., low satn. and low temp. A maintenance of correct diffusion temp. and heating the liquor before the addn. of lime is considered necessary for good filtration; a low temp. disintegrates the cloths because of lime deposits. Most mills consider frequent washing injurious to the cloth. The most frequent range for length of duration showed 20-40 days for cotton, 14-20 (sometimes 35) for jute. Cotton-linen cloths endure 2-5 washings and last 12-35 days, linen is similar. Post-war conditions introduced 40 grades of cloths; 54% are cotton, and 31% are a cotton-jute combination; 15% are linen, cotton and jute combinations. Before the war, 80% of the mills used one brand of cloth. FRANK MARESH

Studies on filter cloths in sugar mills. K. ŠANDERA. Exptl. Inst. Czechoslovakian Sugar Industry. Prague. *Listy Cukrovar.* 47, 235-40(1929).—Samples of filter cloths were obtained from the makers as strips cut along wool and warp and observed for tensile strength. The humidity of the room showed an av. of 58.5% (relative), and the room temp. remained at 19-20°. A microscopic analysis of raw fibers showed uniform fibers and yielded no information as to their analysis; a microscopic picture of the woven fabric yielded a significant classification. Ash, by igniting 1-g. samples, showed cotton to contain 1.1-2, linen 1.2, and jute 1.1-2.5%. Extractable minerals, since they influence the polarity of adsorption, were extd. by boiling water for 2 hrs. Cotton contains more sol. salts than jute (200% more), but the abs. quantities are insignificant.

The rate of removing adsorbed electrolytes (0.002 *N* HCl and 0.01 *N* Na₂CO₃) showed that cotton retains the acid much longer than the alkali. This difference of selective adsorption is not observed for linen-cotton and jute fibers. Tables of the hygroscopicity, mesh, and phys. properties of all brands tested are given. FRANK MARESH

The volume of the bagasse in the mill and its influence on mill settings. G. L. VAN WELIE. *Arch. Suikerind.* 36, II, 926-37, 939-53 (1928).—Instead of using the wts. of cane, juice, and bagasse for mill control, a method is worked out and applied at several mills to control the work with the figures for vol. of bagasse and juice expressed per unit of time. The vol. of the bagasse at the smallest opening in the mill can be considered to be air free, as the air will be dissolved in the juice. Therefore the vol. of bagasse is the total of the vol. of juice in bagasse and the vol. of the fiber in bagasse. The vol. of the juice can be calcd. from the Brix, and the vol. of the fiber is calcd. from the sp. gr. of the fiber, which averages 1.6. The vol. of bagasse passed per unit of time has not the same value as the vol. of the opening of the mill passed at the same time. This difference is due to the slipping of the rollers and reabsorption of juice, and from the proportion of these 2 vols. it follows that at the inlet no slipping and reabsorption occurs; but at the outlet slipping and reabsorption are considerable, the latter being the largest and amounting to 30%. It is pointed out that the place where the maceration water is applied is immaterial, because the mixing of water and bagasse does not take place until they enter the mill. The expansion of bagasse on the turnplate, because of included air, follows a line parallel to the circumference of the top roller and this line might be calcd. from the fiber % bagasse and the vol. of the fiber per revolution. The construction of the turnplates used at the mills where the expts. were made corresponded very closely to the theoretical curve calcd. by V. It is pointed out that just as the success of the mill work depends for a large part on the first unit of the train, so the work of 1 sep. mill depends largely on the extn. at the entrance. van W. has calcd. the proportion of the extn. of the inlet and the outlet from the Brix of the juice from the cane roller, the Brix of the juice of the bagasse roller and the Brix of both juices mixed. By increasing this proportion practical results are obtained at different factories. The best mill work will be obtained when the power used is equally divided over the entrance and the outlet. van W. has calcd. from the vols. of bagasse and juice theoretical openings for the mills, and the results proved to be identical with practical mill settings if, for the outlet, 30% reabsorption was taken into consideration. P. R. P.

Bagasse analysis and mill work. II. HETER. *Arch. Suikerind.* 36, II, 691-729 (1928).—The difference in the results of Khainovsky's warm and cold methods for analyzing bagasse was used by H. to study the mill work exclusive of the effect of maceration. The results of the cold method are lower than those of the warm method, the difference being due to the undild. juice present in unopened cells. Detn. of the no. of unopened cells in the bagasse of each mill was made possible by this method. The app. of Khainovsky was also used for detn. of the vol. of the bagasse. It is pointed out that the purities of the last mill juice and the juice in bagasse are not equal. In order to calc. the purity of juice in bagasse the detn. of the Brix of the extd. liquid was necessary, after it was proved that no material not belonging to the juice was dissolved. The vol. of bagasse extd. by each mill was calcd. from the circumference of the rollers and the revolutions of the engine. The results of the tests at 4 factories, all working with 4 mills each, are given in tables and graphs. It is pointed out that only $\frac{2}{3}$ of the undild. juice in bagasse is available for diln. The amt. of juice remaining in bagasse depends largely on the difference in velocity of the fiber and the expressed juice. Increasing the pressure in the mills does not necessarily result in drier bagasse, this being limited by the phys. condition of the bagasse and the undild. juice in unopened cells. Detns. of the sp. gr. of bagasse should be made frequently in order to know the relation between vol. of fiber and vol. of expressed bagasse; thus the setting and regulating of the mill work can be made more efficient. An app. for detn. of the vol. of bagasse was designed by H. Deep grooves in the cane roller alone are not sufficient to insure high extn.; the bagasse roller must also be provided with deep grooves. The purity of the juice in opened cells in bagasse is always a little lower than that of the mill juice, and that of the juice in unopened cells is considerably lower. At the 4th mill the purity of the juice in bagasse was 15 points lower than that of the mill juice. P. R. P.

The efficiency of a fifth mill. L. W. HOFLAND. *Arch. Suikerind.* 36, II, 911-25 (1928).—Contrary to Emmen (following abstr.) H. concludes that a 5th mill will be profitable at most factories. In a new installation a 5th mill will always pay and for an existing installation the profit will depend on local conditions. P. R. P.

The utility of the 5th mill. Q. A. D. EMMEN. *Arch. Suikerind.* 36, II, 1075-9 (1928).—An answer to the article of Hofland (preceding abstr.). E. still adheres to

his conclusions not to be too optimistic about the financial results of a 5th mill. P. R. P.

The coagulation of active chars. O. SPENGLER AND E. LANDT. *Z. Ver. deut. Zuckerind.* 78, 549-65(1928).—An exptl. study was made of the relation between adsorption and coagulation. Qual. tests were made of coagulating power by the addn. of increasing vols. of salt soln. to a definite wt. of char in H_2O , so that the total vol. was the same in all cases. The cc. of salt soln. which just gave a clear filtrate was a measure of the coagulating power of the salt. The ratio of the molar quantity of these salts required to produce a clear filtrate is $ZnSO_4 : CaCl_2 : NH_4Cl : NaCl$ as 1:2:20:30. Where the char was peptized with $NaOH$, larger quantities of the salts were necessary. That salts at low concns. peptize chars, as does $NaOH$, has not yet been detd., but high concns. of salts bring about coagulation. The polarization photometer was used in making quant. expts., H_2O being used in one chamber and the char suspension in the other. By noting the change of angular rotation per min. required to give fields of equal brightness a measure is obtained of the rate of sedimentation of the char. The results show that the order of coagulating power is (1) methylene blue $> H > K > NH_4 > Li$; (2) $Cu > Pb > Zn$; $Ba > Sr$; $Ca > Mg > H$; (3) $(C_2H_5)_3NH- > (C_2H_5)_2NH_2- > (C_2H_5)NH_2- > NH_4$; also that $NaOH$ has a smaller effect than KCl . The expts. show that chars suspended in water act as negatively charged lyophobic colloids. The work of Freundlich is confirmed, that strongly adsorbed ions have a high flocculating power. E. A. FIEGER

The axial thrust in centrifugal pumps. E. CORDI. *Sucr. Belge* 48, 21-35(1928).—Theoretical aspects are reviewed. The various types of centrifugal pumps and their places in beet-sugar factories are discussed. The importance of giving proper attention to the devices used to overcome axial thrust is well emphasized. E. A. F.

Statistical methods in agronomic experiments. V. G. LAVA. *Sugar News* 9, 812-6, 884-92(1928).—L. mentions 3 general sources of error which affect agronomic expts.: the weather effect, the genetic factor and the soil factor. To minimize the weather effect, expts. must be of long period duration. The use of pure strains and the discarding of yields on the border of each plot will partially eliminate the genetic factor. The soil effect may be minimized by the use of large plots repeated many times, but for small institutions, the use of the Latin Square method or the Beaven's method of laying out plots should be preferred. In the calcn. of the significance of the difference between paired expts., the Besel formula applied to the difference between the yields, or Student's formula should be used; in case there are only a few pairs of observation, Student's formula should be preferred. The calcns. used for illustration are made on data published in *Sugar News* and *The Philippine Agriculturist*. V. G. L.

Value of p_H control in gur refining. K. C. BANERJI. *Intern. Sugar J.* 30, 211(1928).—By using bromothymol blue for continuous p_H tests throughout different stages of refining gur, together with temp. control, it was possible to reduce the unknown loss from about 9 to about 1.6%. Further, the quality of the sugar improved, and although the molasses was twice treated in the pans, no difficulty was experienced in boiling. B. C. A.

Quantitative separation of dextrans from gum arabic. ANDRÉ HAMY. *Station Agronomique de Châteauroux. Ann. fals* 22, 24-6(1929).—In aq. soln. Pb subacetate ppts. gum arabic; the ppt. is redissolved in the presence of sufficient glucose or sucrose, but the solvent action of these sugars can be inhibited or reduced by addn. of alc. In the absence of sugars but in the presence of dextrin, addn. of alc. causes considerable pptn. of the latter, which can be prevented by adding sufficient sugar. The following method has been devised, based on the above observations: to 20 cc. of susp. (contg. about 40 g. dextrin per l.) add 23 cc. of 95% alc. and dil. to 55 cc., let stand a few hrs., filter through a fairly close paper; to 50 cc. of filtrate add 90 cc. of a soln. contg. 5 g. glucose and 8 g. sucrose, then 42 cc. of 95% alc. and 15 cc. of Pb subacetate, shake, let stand overnight, divide into 2 tubes, centrifuge, wash with 50 cc. of 5% Pb subacetate to remove the excess of dextrans and alc., triturate the residue in each tube with 4.3 cc. of 75% sugar soln., add 35 cc. of a mixt. of alc.-Pb subacetate- H_2O (120:27:160), centrifuge, dissolve the ppt. in 4% $AcOH$, ppt. the gum arabic with 10 vols. of alc., let stand overnight, filter through a Gooch crucible, dry at 110° , weigh, ignite, and obtain the wt. of gum by difference. A. PAPINEAU-COUTURE

The principal agrogeological properties of Java cane soils (BOONERO) 15. Sugar, the master preserver (JORDAN) 12. Purification of beet-sugar wastes by stream flow aeration (LEVINE, NELSON) 14. Purification of (sugar house) waste waters (ROSS,

Extracting sugar from beets. R. G. W. FARNELL. Brit. 294,520, Feb. 23, 1927. Beet in the form of cossetts or other divided state is dried before extrn. at a temp. of 100° or lower and at atm. pressure, and while the material is heated the pressure is suddenly reduced to facilitate subsequent diffusion. Cf. C. A. 23, 1523.

Extracting sugar from sirups and molasses. RAFFINERIE TIRLEMONTTOISE. Belg. 348,898; March 31, 1928. The sirup or molasses is mixed with crystals of pure sugar or is spread in a thin layer on crystals of pure sugar.

Refining sugar. B. H. VARNAU and T. B. WAYNE. Brit. 294,800, Sept. 29, 1927. See Fr. 642,854 (C. A. 23, 1522).

Sugar juice. FRITZ BLANKE. Fr. 644,974, Dec. 1, 1927. See Brit. 283,202 (C. A. 22, 4001).

Apparatus for clarifying and thickening "sugar lime" mixtures in the Steffens process or other materials. HENRY G. SCHWARZ. U. S. 1,704,993, March 12.

Dextrose. CHARLES EBERT, WILLIAM B. NEWKIRK and MEYER MOSKOWITZ (to International Patents Development Co.). U. S. 1,704,037, March 5. In order to increase the dextrose content of hydrol, the soln. is subjected to a hydrolyzing operation in the presence of sufficient acid to give the liquor an acidity corresponding to a pH of 2.0 or lower.

Modified starch. C. BERGQUIST (to International Patents Development Co.). Brit. 294,979, Aug. 3, 1927. Various products ranging from boiling starch of low water solv. to dextrin of high soly. are made by heating starch in the presence of Cl. The starch is preliminarily dried so as to contain not more than about 2% moisture and the treatment with Cl may be for 2 hrs. at a temp. of 115–135° and by use of 0.03% to 0.12% Cl depending on the character of product desired. An app. is described.

Calcium halide-starch preparations. HENKEL ET CIE GES. Brit. 294,235, July 21, 1927. The process described in Brit. 244,708 (C. A. 21, 339) is modified by adding, instead of borax, Ca borates or H₂BO₃ compds. adapted to form in the Ca halide starch masses difficultly sol. Ca borates. Examples are given.

29—LEATHER AND GLUE

ALLEN ROGERS

Leather preparation. H. VAN DER WAERDEN. *Chem. Weekblad* 26, 82–91(1929).—An address dealing mostly with Cr and aldehyde tanning. The phys. and the chem. explanations of tanning are developed.

Synthetic tanning materials. A. BLOEMEN. *Chem. Weekblad* 26, 34–42(1929).—A critical survey of the patent literature up to July, 1928. The importance of leather and exts. analysis is emphasized.

The Tacaout gallnuts of Tripolis. G. A. BRAVO. R. Istituto Nazionale Industrie CROIO TORINO. *Boll. ufficiale staz. sper. ind. pelli mat. concianti* 6, 195–9(1928); cf. C. A. 22, 4867.—The Tacaout gallnuts produced by *Eriophyes laiae* Trab on *Tamarix articulata* Vahl. were examd. in respect to their tannin content. The gallnuts possess an approx. spherical shape and a wrinkled surface. They measure 30–80 mm. in diameter, and are of gray, greenish or red-brown color. The quant. analysis yields 36.77–43.91% of tannins and 9.68–16.76% of sol. non-tannins. The aq. ext. gives the following reactions: A soln. of Fe alum produces a dark violet color, and concd. H₂SO₄ first a yellow, then a brown color. With limewater, a brown ppt., and with NH₄CuSO₄ soln., a yellow ppt. is obtained. Expts. conducted on a small scale to exam. the tanning properties of the ext. yielded leather of high quality.

Modern manufacture of leather colors and finishes. J. PERRETT. *Quim. ind.* 5, 234(1928).—The basis of modern leather colors is a powdered pigment suspended in solns. of soap, rubber, casein, albumin, etc. A good pigment should have large covering power, should resist light, be free from Pb, resist H₂S, be inert, smooth, insol. in water and free from vegetable org. matter. Fe oxides and sienna earths are used, English oxide being the best because of its uniformity; however, it is more expensive. Ti and Zn oxides are the white pigments. To produce finishes, lac gums may be used; the method is given for handling the gums. Casein adds brilliancy to leather, the best casein coming from milk. Blood or egg albumin gives five finishes. Waxes increase the covering

power and brilliancy but also fill up the pores. Waxes are often adulterated with the materials indicated; an examination for these is mentioned. Agar and gelatin impart smoothness to leather; different gelatins are available for different leathers. Irish-moss mucilage also is useful.

S. L. B. ETHERTON

Photometric and electrometric measurements of gelatin behavior (BRIEFER) 2. Consistency of animal glue (BROUSE) 2. Wetting agents for animal and vegetable materials [for chrome tanning] (Brit. pat. 294,890) 18. Treating polluted waste water (U. S. pat. 1,703,373) 14. Waterproofing and preserving composition for leather (Austrian pat. 112,121) 25. Dye for leather (Fr. pat. 644,637) 25.

Unhairing skins. SOCIÉTÉ INDUSTRIELLE DES APPLICATIONS CHIMIQUES. Belg. 348,488, Feb. 29, 1928. The skin is soaked, freed of its coarse impurities while exposing it to a temp. which can affect the phys. condition of the pores, and is allowed to stand in unhairing baths consisting of refined Na_2S or refined Na_3AsS_3 . In this way the hair or wool is uninjured.

Dressing fur skins. E. AUTISSIER and R. STASSART. Belg. 350,564, May 31, 1928. The skins are treated in a fulling engine, or other closed agitating machine, with a soln. contg. Cr, *e. g.*, a 4–6° Bé. soln. contg. Cr hydroxide, HCl and KOH.

Tanning hides. J. G. KÄSTNER and C. H. TRÖGER. Brit. 294,996, Aug. 3, 1927. Penetration of hides by tanning liquors is facilitated by the use of various substances such as bates, bacterial cultures, gases such as CO_2 and N, electronic radiations from radioactive substances or tubes, filtered spectrum radiations, alternate applications of a vacuum and elec. current or of vacuum and pressure. Colloids such as a carob bean ext. also may be used; the addns. and treatments mentioned may be used also to facilitate oiling or greasing of chrome leather. Cf. C. A. 22, 4869.

Tanning hides. C. H. TRÖGER and J. G. KÄSTNER. Brit. 294,997, Aug. 3, 1927. A colloid consisting of an ext. of carob beans or similar material is added to tanning liquors; their penetration is improved by the use of bates, fermenting substances such as yeasts, cultures of bacteria, gases or radiations from radioactive substances or electronic tubes. An elec. current and alternations of pressure and vacuum may also be used to facilitate penetration of the tanning liquor.

Chromium compounds for tanning or dyeing. E. BAUMGARTNER. Brit. 294,965, Aug. 2, 1927. Chromic compds. suitable for use in tanning and dyeing or rust-proof paints are formed by the reaction of a soln. of Cr sulfate of a basicity corresponding to the formula $\text{Cr}_2\text{O}_3 \cdot \text{SO}_3$ and a concn. of about 20% Cr_2O_3 , with an alkali, neutral salt, or salt of a "feeble acid," *e. g.*, with NaOH, Na_2CO_3 , NaHCO_3 , Na_2SO_4 , Na formate, NaOAc, Na monochromate or NH_3 .

Rotatable wooden tanning and washing drum. MARCEL BRETON and PIERRE JACOUT. Ger. 470,658, Feb. 23, 1927.

Treating leather. AMBROSE H. ROSENTHAL. U. S. 1,705,311, March 12. In order to give a metallic appearance, leather is treated with a coating of Bi oxychloride in soln., a coating of nitrocellulose soln., a coloring medium such as an alc.-sol. color, a second Bi oxychloride soln., and a flexible varnish.

Moistening, oiling and embossing leather. ALFRED O. T. BEARDMORE. U. S. 1,704,718, March 12. A tanned hide is caused to absorb 20–25% of its wt. of water, kept in a closed room at ordinary atm. temp. until the moisture has become distributed throughout the material of the hide, air currents being avoided, sprayed with a mixt. of vegetable and mineral oils heated to about 60°, rough rolled and then embossed.

Decorating unfinished leather. WINTHROP S. LAWRENCE (to Kaumagraph Co.). U. S. 1,703,675, Feb. 26. Leather is connected to a mount such as cardboard by the use of an adhesive contg. a drying oil such as a lithographic varnish and cobalt drier, the adhesive is caused to set without permitting it to enter the pores of the leather sufficiently to stiffen it; the exposed surface of the leather is then printed on before the leather is sepd. from the mount.

30—RUBBER AND ALLIED SUBSTANCES

C. C. DAVIS

Rubber patents in relation to the patents and designs acts. H. DOUGLAS ELKINGTON. *Trans. Inst. Rubber Industry* 4, 336–42(1928).—The discussion refers to English law.

C. C. DAVIS

Practical method for obtaining dry air for humidity control in a rubber laboratory.

F. S. CONOVER. N. J. Zinc Co., Palmerton, Pa. *Ind. Eng. Chem.* 21, 162-4(1929).—Air previously dried by passage through silica gel is blown through the storage chambers. With 2 silica dehydrators, continuous drying is possible, the air being forced through one dehydrator while the other is being reactivated by treatment with air at 155-70°. Cooling and heating systems complete the equipment.

Researches on the structure of rubber. PAUL BARY AND ERNST A. HAUSER. *Rubber Chemistry & Technology* 1, 401-9(1928).—See *C. A.* 22, 4005.

The preparation of pure rubber from latex by means of alkali and its separation into sol-rubber and gel-rubber. RUDOLF PUMMERER AND HANS PAHL. Univs. of Erlangen und Greifswald. *Rubber Chemistry & Technology* 1, 167-76(1928).—See *C. A.* 22, 885.

Preliminary report on the coagulation phenomena and hydrogen-ion concentration in the latex of *Hevea brasiliensis*. N. H. VAN HARPEN. Algemeen Proefstation der A. V. R. O. S., Medan (Nederlandsch-Indië). *Arch. Rubbercultuur* 13, 44-60(1929); (In English 61-77).—The lack of general agreement among theories explaining the nature of coagulation in *Hevea* latex led to a study by a different method in which the part played by the p_H value was particularly investigated. The H-ion concns. at the different stages of coagulation were measured by phys.-chem. methods by aid of the quinhydrone electrode. With this method, the irregular transition points of the coagulation process could be detd. with great precision. The transition point from the 2nd liquid zone to the 2nd coagulation zone appeared to occur at a p_H value of 0.80, and the transition point from the 2nd liquid zone to the 1st coagulation zone at a p_H value of 3.49. The transition from the 1st liquid zone to the 1st coagulation zone could not be fixed at a definite p_H value, for it varied between p_H 5.05 and p_H 4.77, depending upon the diln. of the latex. By the use of buffer solns. at the transition between the 1st liquid zone and the 1st coagulation zone, the existence of a flocculation zone with dild. latex was proved. This zone began at a p_H value of 5.05 and terminated at a p_H value of 4.77, beyond which point the flocculates coalesced to form a coagulum. When prepd. from fresh latex contg. no preservative, B liquid behaved abnormally in the 1st coagulation zone, in that no coagulation took place between p_H values of 4.77 and 3.49. On the other hand, with fresh latex, with latex preserved with NH_3 and with B liquid from ammoniated latex, coagulation took place in the normal manner between p_H values of 4.77 and 3.49. The occurrence of flocculation between the limits of p_H 4.77 and 3.49 with this B liquid prepd. from fresh latex cannot be explained by the absence of an enzyme (the coalse) but more probably can be explained by the inactivation of some unorganized chem. substance which normally causes flocculation at a p_H value of 4.77 and acts as a coalescing agent. It appears that a resinous substance in NH_4OH soln. not only causes flocculation at a p_H value of 4.78, but also begins its coalescing action at the same p_H value, and that very small quantities of this substance are sufficient to coagulate large quantities of latex. The supposition that the resinous substances which are present in latex, either as resins or otherwise, are responsible for coalescence is very probable and further investigations on coagulation phenomena should be directed into new fields on the basis of this hypothesis. When used a coagulant Na_2SiF_6 behaved in an unusual way, the p_H values being almost the same (3.25) at different concns., and the solns. acting like buffer solns. On titration Na_2SiF_6 behaved as if it had 4 available H ions, and therefore it can be considered as a combination of $2NaF + SiF_4$, the latter hydrolyzing to $Si(OH)_4$ and $4HF$. If so, a buffer soln. would form from the combination $2NaF.4HF$. To prove this, the dissocn. of HF at various concns. at 26° was detd. The solns. were buffered with NaF . It was found that the concn. relationship in the buffer soln., i. e., the ratios of the HF and NaF components, was 1. A test soln. contg. equal mol. concns. of HF and NaF was found to be a buffer soln. with a p_H value of 3.25. Na_2SiF_6 is dissocd. in water like a buffer soln. contg. 1 mol. of NaF and 1 mol. of HF . The strongly acid reaction resulting from the hydrolysis of Na_2SiF_6 can perhaps be best explained by the reaction: $Na_2SiF_6 + nH_2O \rightleftharpoons 2(NaF.HF) + SiOF_2(n-1)H_2O$.

Making rubber goods of latex by electrodeposition. PAUL KLEIN. *Trans. Inst. Rubber Industry* 4, 343-51(1928); cf. *C. A.* 23, 1305.—App. and graphs are given showing the rate of deposition, deposition as a function of the c. d., the cond. and concn. of latex and stress-strain curves of the deposited product.

The effect of sunlight on the color of cured and of uncured accelerated mixes. R. DEFRIES AND W. J. S. NAUNTON. *Trans. Inst. Rubber Industry* 4, 298-300(1928).—Rubber mixts. contg. crepe 100, ZnO 10, BaSO₄ 100 and S and accelerator (diphenylguanidine, di-*o*-tolylguanidine, triphenylguanidine, mercaptobenzothiazole, thiocarbanilide, aldehyde-ammonia, tetraethylthiuramdisulfide and Zn diethyldithiocarbamate) were exposed to ultra-violet light (1) before curing but not afterwards, (2) only after curing, and (3) both before and after curing. These series of exposures were made independently in N and in O. With all accelerators, exposure before curing gave no visible effect, but after curing the samples so exposed were much darker than the unexposed samples. Furthermore exposure of the cured samples lightened those which had not been exposed before curing, but failed to lighten those which had been exposed before curing. The discoloration was proportional to the time of exposure and varied with the accelerators. When the samples were irradiated in O before curing, the discoloration was only slightly more in O than on those irradiated in N before curing, while subsequent bleaching in O was far greater than in N. Ultra-violet light induces oxidation of the vulcanizates, which was supported by the fact that bleaching was also effected by H₂O₂. When the samples were undercured, the 2nd exposure to light intensified the darkening. The results indicate that (1) exposure of uncured samples causes a surface vulcanization; (2) the discoloration is an effect of a surface overcure produced by normal vulcanization superimposed on an already slightly vulcanized surface and (3) bleaching of vulcanizates by light results from oxidation, since it can be minimized by exposure in an inert gas and can be produced by oxidizing agents. When, however, there is an excess of vulcanizing agents to permit after-vulcanization, the subsequent exposure induces further darkening instead of bleaching. These effects also take place in sunlight, and it was their prevalence in technical mixts which led to the more systematic expts. with ultra-violet light. C. C. DAVIS

The mechanism of the reinforcement of rubber by pigments. HARLAN A. DEFEW. N. J. Zinc Co., Palmerton, Pa. *Rubber Age* (N. Y.) 24, 378-81(1929).—In a recent paper on pigment reinforcement as a function of resistance to tearing and resistance to cutting (cf. C. A. 22, 3064), it was reserved for the present paper to explain the mechanism of this reinforcement. Pigments may exist in rubber as: (1) soft pellets of undisintegrated pigment; (2) agglomerates of adherent massed particles; (3) dispersed particles and (4) flocculated particles. (1) and (2) have no reinforcing effect; in fact they are in effect the same as porosity. If a fine pigment is not easily wet by rubber, there is a tendency to flocculate. The contrast between flocculation and dispersion (complete wetting) is illustrated by the familiar expt. of liquefying a stiff paste of ZnO and kerosene with a suitable agent (cf. Breyer, *Rubber Division, Am. Chem. Soc.*, Pittsburgh, 1922; Bierer and Davis, C. A. 22, 883). During the early stage of hot vulcanization rubber is semi-fluid and the ultimate distribution of the pigment is influenced greatly by this condition, both dispersion and flocculation proceeding during this stage of vulcanization. Flocculated pigment increases the hardness of rubber and therefore the resistance to cutting, while dispersed pigment increases the resistance to tear. Resistance to tear is increased by dispersed pigments because they act as obstacles in the path of the tear, so that the component of the force in the direction of tear is diminished. Accordingly with a fine pigment it is possible to increase the resistance to tear even when the bond between rubber and pigment is much weaker than the rubber itself. Hardness caused by flocculation is explained on the theory that the pigment assumes a rigid structure. When rubber is elongated, flocculated pigment and large particles cause uneven stresses which lower the reinforcing

effect below that otherwise obtainable. ZnO is so easily wet by rubber that there is little tendency to flocculate regardless of the particle size. It does not, therefore, increase hardness, but tests show that the resistance to abrasion and to tear of mixts. contg. ZnO increases with decrease in the particle size of the ZnO. C. C. DAVIS

Specifications for rubber goods and the value of performance tests. J. M. BIERER AND C. C. DAVIS. *Rubber Chemistry & Technology* 1, 146-62(1928).—See C. A. 22, 883. C. C. DAVIS

New points of view in the analysis and classification of reclaimed rubbers. EUGENIO LINDMAYER. *Kautschuk* 4, 278-80(1928).—In conjunction with the rubber content of a reclaim, its CHCl_3 ext. (after extn. with acetone) is a measure of the degree of "devulcanization" of the rubber. According to the theory of vulcanization already enunciated by L. (cf. C. A. 20, 3837), the chief reactions of devulcanization are: $(\text{C}_6\text{H}_5)_3\text{S}(\text{C}_6\text{H}_5)_3 \rightarrow (\text{C}_6\text{H}_5)_3\text{S}(\text{C}_6\text{H}_5)_2 + 2(\text{C}_6\text{H}_5)_2\text{S}$ and $2(\text{C}_6\text{H}_5)_2\text{S} \rightarrow (\text{C}_6\text{H}_5)_4\text{S}_2$. From this, 51.65% of the originally sulfurated rubber would remain insol. in CHCl_3 , while 48.35% would become sol. in CHCl_3 . Though side reactions take place, this reaction is predominant enough so that the degree of devulcanization can be judged by the approach to this theoretical value of 48.35%. Examn. of 40 samples of reclaimed rubber of various types and from various sources showed a wide variation in this value. In no case did it exceed the theoretical 48.35% (which is termed "100% degree of devulcanization") while the nearest approach was a sample with a rubber content of 64.21%, which had a 94.59% degree of devulcanization. Detns. of the degree of devulcanization, i. e., the relation between the CHCl_3 ext. and the rubber content, are useful in controlling reclaiming processes and in adapting a process to a particular type of raw material. In connection with the detn. of the rubber content, the C black content must also be detd., and no general method has been available. A procedure for detg. C black is described which is claimed to give excellent results. Finely divide the sample, ext. successively with acetone, concd. KOH and concd. HCl, wash with water, dry and incinerate in a combustion tube 80 cm. long (contg. PbCrO_4) in a Bunsen-Erlenmeyer furnace, as in regular org. analysis. From the quantities of CO_2 and H_2O , the C black may be estd. The C corresponding to C_6H_5 is considered to be the C in the rubber component, and therefore the C in excess of that corresponding to C_6H_5 is regarded as C black, and is calcd. merely by subtracting from the total C that contained in the C_6H_5 value. An idea of the proportion of bituminous substances may be had by a colorimetric examn. of the CHCl_3 ext. C. C. DAVIS

The history of "mineral rubber." WERNER ESCH. *Kautschuk* 4, 252(1928); *Caoutchouc & gutta-percha* 25, 14233(1928).—Further comments on the origin of the term "mineral rubber" (cf. Luttringer, C. A. 22, 4870). C. C. DAVIS

The history of "mineral rubber." A. D. LUTTRINGER. *Kautschuk* 4, 277(1928).—Comments on an article by Esch (cf. preceding abstr.). There is uncontrovertible evidence that the term "mineral rubber" was in common use in England a century ago to designate the natural product of Derbyshire. C. C. DAVIS

The gelatination of Vultex (appendix to the communication entitled "Dispersoidological investigations of latex"). P. P. VON VEIMARN. Imp. Tech. Res. Inst. Osaka (Japan). *Kolloid-Z.* 46, 223-5(1928).—As was to be expected from the fact that the particles of vulcanized latex are less plastic than those of raw latex, the jelly obtained from vulcanized latex by a dispersator like Lili soln. is less adhesive and coherent than the corresponding jelly from raw latex. Expts. show, however, that under sufficiently great pressure the jelly from vulcanized latex acquires great elasticity and strength. When a film is obtained by evapn., capillary forces residing in the non-rubber components have the same effect as artificial pressure, the rubber contents of the particles combine, and the film shows a high elasticity. The view that the coherency depends upon the adhesion of the surface layers of non-rubber components is considered erroneous (cf. Hauser, *Latex*, 130). The plastic, strong films which surround latex particles

consist of a mixt. of protein, resin and rubber and have no more influence on the phys. properties of the rubber obtained by gelatination or coagulation than "active" fillers. The less the fibril structure of a coagulum is destroyed, the greater the elasticity of the coagulum. The plastic shells of latex particles become gelatinous and soft with dispersators of proteins and disintegrate on application of slight pressure. Therefore in ordinary coagula which have undergone mech. treatment, the particles do not retain their individuality but disrupt, the rubber contents flowing together, and a fibril structure being acquired when the coagulum is stretched under suitable conditions. These fibrils in films or jellies from latex show a characteristic behavior, such as a tendency to form spiral masses when ruptured, and such great elasticity that they can be elongated to a point where they become invisible in the ultra-microscope. Six photomicrographs are included.

Problems of vulcanization. J. DUGUÉ. *Rev. gén. caoutchouc* 5, No. 47, 9-12 (1928); cf. C. A. 22, 2682, 3316.—Comments on articles by Bacon (cf. C. A. 22, 3804) and by Bary (cf. C. A. 23, 546). The point of view is taken that below its m. p., S can only be disseminated or dispersed in rubber and that none dissolves. Furthermore it is considered that S is not the vulcanizing agent, for it occurs in the same proportion in the phase of a vulcanizate which is sol. in C_6H_6 and in the phase which is insol. Vulcanized rubber is a mixt. of hard rubber ($C_{10}H_{16}S_2$) and raw rubber. Other features are discussed briefly.

C. C. DAVIS

A comparison of the rate of combination of sulfur with rubber and the rate of vulcanization. E. R. BRIDGWATER. Du Pont de Nemours & Co. *Rubber Age* (N. Y.) 24, 439-41 (1929).—The object of the expts. was to ascertain why rubber cured with an org. accelerator to the optimum phys. state has a lower coeff. of vulcanization than rubber cured without such an accelerator, and why at the optimum phys. state the coeff. also varies with the org. accelerator. The problem was studied by curing to different extents rubber-ZnO-stearic acid mixts. with different proportions of S and of accelerators and detg. the combined S, the stress-strain curves and the power to absorb C_6H_6 . The results admit of several conclusions. The low combined S at optimum cure which is characteristic of mixts. with a high rate of vulcanization is ascribed to the combined effects of a stiffening or polymerizing action of the accelerator and the relatively small heat degradation in the short cures. With "Vulcanol" the rate of combination of rubber and S is slower and the rate of stiffening of the rubber mixt., i. e., the progress of phys. vulcanization, is more rapid than with mercapto-benzothiazole. This difference can be explained only by the fact that some accelerators have a greater phys. stiffening or polymerizing effect than do others. Under the same conditions otherwise, accelerators differ in the influence which they have on the tendency of a rubber mixt. to absorb C_6H_6 . Neither the stress-strain curve nor the combined S gives any information about this tendency to absorb C_6H_6 . At any particular state of cure, the power to absorb C_6H_6 depends more upon the rate of vulcanization than upon the accelerator, and the higher the proportion of the latter the smaller is the absorption of C_6H_6 . The small tendency of mixts. cured with a high proportion of S to swell in C_6H_6 is probably related to the high rate of vulcanization, for such mixts. with little tendency to absorb C_6H_6 have a low combined S content. In no case in the expts. did curing beyond the point of max. stiffness (judged by the stress-strain curve)

diminish the power of absorbing C_6H_6 . This absorptive power depends nearly as much upon the rate of vulcanization as upon the state of cure, a fact which is of importance in the formulation of *rubber mixts. to resist oil*. Such oil resisting mixts. should be highly accelerated but not overcured.

C. C. DAVIS

Some features of sulfur in rubber manufacture. DOUGLAS F. TWISS. *Rubber Chemistry & Technology* 1, 346-55(1928).—See *C. A.* 22, 2491.

Treating rubber latex. I. G. FARBENIND. A.-G. Brit. 294,804, Oct. 10, 1927. A viscous paste which can be readily redispersed by use of aq. NH_3 is prepd. by quickly mixing with latex sufficient acid to give a p_H less than 2 and then (suitably after about 24 hrs.) filtering off the serum. Fillers, protective colloids, S, etc., also may be added.

Treating latex. I. G. FARBENIND. A.-G. Brit. 294,412, Nov. 12, 1927. Latex is preserved by the addn. of small quantities (suitably 2-5%) of sol. salts of sulfonic acids possessing soap-like properties. The addn. improves the penetration when the latex is used for impregnating paper or other materials and the materials in such processes may also be treated with salts such as are admixed with the latex. Several examples are given.

Variegated rubber. C. MACINTOSH & CO., LTD. and S. A. BRAZIER. Brit. 295,080, May 21, 1927. Pieces of rubber of the same or different colors are coated with a rubber soln. of a contrasting color, dried and agglomerated into a mass which has a variegated surface.

Synthetic rubber. I. G. FARBENIND. A.-G. Brit. 294,661, July 28, 1927. Polymerization of hydrocarbons such as butadiene, isoprene, dimethylbutadiene or their analogs by means of O or a substance yielding O, or both, in an aq. medium as described in Brit. 283,840 (*C. A.* 22, 4274), is effected in the presence of a metal salt of an inorg. or org. acid such as salts of Co, Pb, Mn, Cr, Ni or Ag. Several examples are given. Cf. *C. A.* 23, 310.

Synthetic rubber. I. G. FARBENIND. A.-G. Brit. 294,963, Aug. 2, 1927. Polymerization of butadiene, isoprene or similar hydrocarbons is effected in the presence of water by a substance which exerts a hydrotropic action, such as a salt of an org. sulfonic or carboxylic acid or a substitution product of such an acid or an acid obtained from the degradation of albumin or an acid amide. The substance can either be added as such or can be produced *in situ* by adding an alkali, metal oxide or metal carbonate or acid of suitable character. O or O carriers may be present during the process. Examples are given of the treatment of isoprene and butadiene with water at a temp. of about 60° in the presence of casein and K cinnamate, blood albumin and Na tetrahydronaphthalene sulfonate, Mg isobutyl-naphthalene sulfonate and O, and egg albumin and Na stearate.

Rubber-like substance from mineral oils. EDGAR W. HULTMAN (one-fourth each to Francis P. Duncklee, Joseph Monteleone and Walter R. Simons). U. S. 1,704,194, March 5. A mineral oil material such as "Dubbs pressure distillate," topped Calif. crude oil or other similar oil or fraction, substantially free from constituents b. below 200°, is partially polymerized (suitably by use of oxides of Ce or Sn at a temp. of about 95°), then cooled and treated with an activated reducing gas such as CO or CH_4 in

the presence of Ni, Pd or other catalyst at a temp. below that used in the polymerizing reaction (suitably at a temp. of about 32°), treated with a halogenating reagent such as Cl, Br or B fluoride, to produce a soft rubbery product in the resulting oily material, and sepn. is then effected.

Preserving rubber articles. A. FORNER. Brit. 294,632, July 29, 1927. The surface of articles such as tires is treated with a mixt. of French chalk and a gum solu with or without a soln. of "cellulose." The mixt. may be thinned with "benzole or benzene."

Molding hollow rubber balls. K. KUROKAWA. Brit. 295,175, Dec. 19, 1927. An app. is described.

Core for single-tube tires. SCHUYLER C. HATFIELD. U. S. 1,704,538, March 5. Cores are formed with a filling of comminuted material such as sand surrounded by a thin casing of sol. material such as glue, shellac or rosin which can readily be removed from the tube by washing.

Traveling band filter suitable for filtration of aqueous rubber dispersions. A. SZEGVARI and C. M. SPENCER (to Anode Rubber Co., Ltd.). Brit. 294,215, July 20, 1927. Metal parts of the app. are preferably made of stainless steel and various structural features are described.

Rubber solution for coating wood, metal or other materials. CHARLES E. BRADLEY and WILLIS A. GIBBONS (to Naugatuck Chemical Co.). U. S. 1,703,920, March 5. Halogenated rubber treated with S chloride is dissolved in benzene and solvent naphtha. Boiled linseed oil, etc., may be added.

Apparatus for coating, impregnating or electrophoretic deposition of rubber. A. SZEGVARI (to Anode Rubber Co., Ltd.). Brit. 294,153, July 18, 1927. An app. is described in which the homogeneity of an aq. dispersion such as rubber is maintained by circulating the dispersion through a tank or chamber in a continuous stream and filtering it during circulation to remove particles above a certain desired size.

Deposition of rubber. THE ANODE RUBBER CO., LTD. Fr. 645,779, Dec. 15, 1927. Org. material, particularly rubber, is deposited electrophoretically on supports which are cooled below the temp. of the bath so as to remove the heat caused by the current, or sep. cooling means may be employed.

Composite rubber flooring manufacture. JOHN B. LOSEY and WALTER R. STONE. U. S. 1,703,312, Feb. 26. Mech. features.

Adhesive. MARY A. F. ALLEN. Australian 10,707, Dec. 3, 1927. An adhesive consists of 2 co-acting fluids, the first rubber latex or rubber emulsion and the second a soln. of raw or unvulcanized rubber in CCl_4 or C_6H_6 . Na_2SiO_3 may be added to the latex to reduce its viscosity.

Polymerized vinyl compounds of rubber-like character. I. G. FARBENIND. A. G. Brit. 294,474, July 23, 1927. Polymerization of substances such as vinyl esters or ethers is effected in the presence of substances imparting improved elasticity to the product such as proteids or their degradation products such as peptones, peptides, diketopiperazines and amino acids and other N compds. preferably of high mol wt. Examples are given of the use of casein with vinyl acetate, albumin with vinyl acetate, glyccoll with vinyl acetate and naphthalene with vinyl acetate. The products may be vulcanized, with or without accelerators, fillers and plastifiers.

Vulcanizing rubber. WINFIELD SCOTT (to Rubber Service Laboratories Co.) U. S. 1,703,902, March 5. Vulcanization with S is accelerated by use of a reaction product of diphenylguanidine with 1-keto-2-methyl-4-thio-3,5-benzenedithiol. Cf. C. A. 23, 732.

Apparatus for vulcanizing small objects such as dental plates. MAXIME PAULMIR. Fr. 644,748, Nov. 30, 1927.

CHEMICAL ABSTRACTS

Vol. 23.

MAY 10, 1929

No. 9

1—APPARATUS AND PLANT EQUIPMENT

W. L. BADGER

The importance of the German machinery industry for manufacturing chemical apparatus for use at home and abroad. ERNST BLAU. *Chem.-Ztg.* 53, 6-8(1929).—A classification of app. used in the chem. industry and available from German manufacturers. W. C. EBAUGH

Methods and apparatus used in the cryogenic laboratory. XX. High-vacuum pump of large capacity. W. GAEDE AND W. H. KEESOM. *Proc. Acad. Sci. Amsterdam* 31, 985-8(1928).—See *C. A.* 23, 1311. E. C. M.

Conserving hydrogen sulfide gas in the laboratory. G. N. QUAM. *Chemist-Analyst* 18, No. 2, 14-6(1929).—A scheme is recommended for restricting the flow of H_2S from individual taps by placing capillary tubing in front of each tap. W. T. H.

Inexpensive filter for milk of lime. M. G. BUICKOVSKI. *Bull. Sakharotresta (Bull. of the Sugar Trust)* 1928, No. 9, 37-8.—Description and drawing of a rotatory filter for preventing the passage of sand with the milk of lime into the carbonation tank. V. E. BAIKOW

Experiments on filtering crucibles with porous bottom plates. S. GERICKER. *Chem.-Ztg.* 53, 119(1929).—Comparative tests made by using crucibles "HB" and "O" made of porcelain and glazed only on the outer walls for detg. 6-8 constituents gravimetrically and others qualitatively, showed them to be suitable only for the filtration and ignition of Fe_2O_3 . It is suggested that if the inner wall, as well as the outer, were glazed, the results would probably be better. W. C. EBAUGH

Method for filtering colloidal substances. YVES A. FISSIAULT. *Chemist-Analyst* 18, No. 2, 17(1929).—A suction filter composed of a glass funnel contg. a Ni cone, a layer of cotton and a layer of sand is recommended. W. T. H.

Apparatus to prevent creeping of solvents in evaporation vessels. ARTHUR B. KNOBEL. *Chemist-Analyst* 18, No. 2, 17-8(1929).—Suspend an inverted funnel over the dish and apply suction. The funnel should be smaller in diam than the dish. The evapn. is more rapid and practically all of the residue is left at the bottom of the dish instead of on the side walls. W. T. H.

The pycnometer. LEO G. DAKE. *Chemist-Analyst* 18, No. 2, 14(1929).—The making of a suitable tare is described. W. T. H.

Modification of the Hempel gas pipet. GEO. H. W. LUCAS. *Toronto Univ. Ind. Eng. Chem., Anal. Ed.* 1, 79(1929).—A 0.5-cc. bulb in the capillary of the pipet prevents droplets of the absorbent from being forced back into the tubing and the gas buret. A. S. CARTER

The "thermoplanktometer." R. KOLKWITZ. *Ber. deut. botan. Ges.* 47, 64-7 (1929).—This is an apparatus designed to det. the sp. gr. of sea water with an accuracy of 1 part in 10,000. With the aid of a thermometer graduated to $1/10$ of a degree the temp. at which a suitable float will remain suspended is detd. and the sp. gr. calcd. LAWRENCE P. MILLER

Drayton M. S. differential humidity regulator. THE DRAYTON REGULATOR AND INSTRUMENT CO., LTD. *Textile Recorder* 47, No. 550, 44(1929).—This instrument, which is operated from the wet-bulb temp., is provided with a device for varying the setting of the regulator in proportion to the rise in the dry-bulb temp., thus maintaining a fixed relative humidity at varying temperature. The app. is described and illustrated. RURY K. WORTNER

An air separator for determining the grain size of dust. H. W. GONELL. *Tonind.-Ztg.* 53, 247(1929).—A detailed description is given of an app. for the quant. segregation of dust particles according to grain size. Sepn. is made with an air blast through a hollow cylinder. Sizing smaller than that possible with sieves can be made. This method is preferable to elutriation for materials affected by water. The process is not influenced

by the usual variations in room temp. Calcns. are based on Stoke's law, which is applicable only to particles approximating a spherical or cubical form, and is not valid for particles in the form of thin plates or small threads.

R. F. F.

Complete sludge-washing plant in a single unit. A. ANABLE. The Dorr Co. *Ind. Eng. Chem.* 21, 223-6(1929).—A tray-type thickener is used as a washing thickener, but the trays operate in series, not in parallel. Its application to recausticizing and sepn. of Fe cyanide soln. from a ppt. is described.

L. A. PRIDGEON

The construction of various new steam-regulating devices for pipe-lines. H. WINKELMANN. *Apparatebau* 41, 40 2(1929).—Descriptions, with 6 cuts, of Borsig valves.

J. H. MOORE

Construction and standardization of an interferometer pressure gage. J. J. MANLEY. *Proc. Phys. Soc. London* 40, 57-61(1928); *Science Abstracts* 31A, 418. This paper deals with the application of a Michelson interferometer to the detn. of gas pressures ranging from 0.0001 to 20 mm. of Hg. The construction of the instrument is fully described, as are also the methods used for standardizing the registering micrometer screw and its graduated head. The gage can be instantaneously set and the pressure which obtained at the moment of setting measured at leisure.

H. L. D.

A simple way for removing condensate. HANS RICHTER. *Chem.-Ztg.* 53, 32 (1929).—The new Gestra app. (Gustav Gerdts, Bremen), a labyrinth canal or passage way without moving parts, is praised for its economy and efficiency in removing condensate.

W. C. EBAUGH

Technical and economic aspects of machinery for the production of the colloidal state. FELIX HEBLER. *Farben-Ztg.* 34, 834-6(1929); cf. *C. A.* 23, 4. —Compared with a ball mill, a colloid mill (Plauson's) was more rapid qualitatively but required more power. The ball mill reduced 50% of a charge of 200 kg. solids to colloidal dimensions in 200 hrs. with an expenditure of 140 kw hrs. Operating on charges of 5 kg., the colloid mill was able to reduce but 26-31% to colloidal dimensions. For a total of 200 kg., the time required was equiv. to 10 8-30 hrs. with an expenditure of 150-550 kw hrs.

G. G. SWARD

Crushing, pulverizing and grinding machinery. W. BULLOCK. Fraser and Chalmers' Eng. Works, Sir John Cass Tech. Inst. *Chem. Age* (London) 19, 477-81(1928). —Methods of crushing, pulverizing and grinding both wet and dry with available machinery are described.

L. A. PRIDGEON

Furnace arches. D. J. DELMOTTE. *Chaleur Ind.* 9, 232-4(1929).—Chem. corrosion of the arch by fuel or ash may be diminished by judicious choice of the refractory. Mech. erosion by the flame can be avoided by modifying the position of the arch with regard to the gaseous circuit. Once a cavity starts, destruction of the arch is accelerated. It is not advisable to increase arch thickness to avoid collapse. The only practical solution is to reduce the temp. of the intrados by increasing the degree of heat transmission. A "suspended arch" construction is preferable, avoiding joints parallel to the direction of the flame; the thickness of the arch should not exceed 250 mm.

S. L. B. ETHERTON

The heat capacities of organic compounds at low temperatures. II. A low-temperature thermostat. Thousandth degree copper-constantan thermocouple reference tables from 85° to 310° K. JOHN C. SOUTHARD AND DONALD H. ANDREWS. Bartol Research Foundation. *J. Franklin Inst.* 207, 323-39(1929).—A low-temp thermostat, const. to 0.001°, is constructed of a cylindrical Cu vessel, which contains pentane and which is wound on the outside with a heating coil; this is placed inside a vacuum flask which in turn is placed inside another vacuum flask that contains liquid air. A photoelec. cell, sensitive to the light reflected from a galvanometer mirror, regulates the relay in the thermostat heater circuit. Formation of an explosive mixt. of air and pentane through fracture of the smaller vacuum flask is prevented by the use of the Cu container. A change of the thermostat temp. can be made in 1 hr. or less, and the consumption of liquid air is about 2 l. per day. Four Cu-constantan thermocouples were calibrated against standard Pt-resistance thermometers at intervals of 10° between 90° and 180° K inclusive. The equation, $E = E_0 - 0.447 T^{1.009}$, with a deviation curve, was used to calc. the values in the standard reference tables, which give the abs. temp. at intervals of 20 microvolts between 273° and 310° K. and of 10 microvolts between 85° and 273° K.

F. D. ROSSINI

Thermostat for polarimetry. L. RAMBERG AND J. F. HEUBERGER. *Svensk Kem. Tid.* 40, 227-9(1928). (In German).—An electrically heated thermostat is provided with a support for holding a polariscope tube between 2 glass windows. The temp. is controlled by a Ramberg regulator (cf. *C. A.* 18, 3297).

A. R. ROSS

Measuring thermal expansion of pottery body [dilatometer] (YOSHIOKA) 19.
Applications of centrifugal machines to various problems in gas transport (FARAGGI) 21.

HAUSBRAND, E.: *Evaporating, Condensing and Cooling Apparatus*. London: Ernest Benn, Ltd. 4th ed., revised and enlarged. 32s. 6d., net.

MÜLLER-LÜBECK, KURT E.: *Der Quecksilberdampf-Gleichrichter*. Band I. *Theoretische Grundlagen*. 217 pp. Bound, M. 15. Band II. *Konstruktive Grundlagen*. 350 pp. Bound, M. 42. Berlin: Hirschwaldsche Buchhandlung.

Laboratory mill suitable for comminuting drugs, fertilizers, feedstuffs, etc. SAMUEL W. WILEY. U. S. 1,706,643, March 26. Structural features.

Apparatus for grinding ores, coal, etc., and separating the finer particles by the action of a fan. P. L. CROWE. Brit. 295,430, May 11, 1927.

Sorting machine for ore and similar material. N. N. ZHUKOVSKII. Russ. 5268, Sept. 15, 1924.

Electrical thermometer. G. P. KULBUSCH and A. M. KALININ. Russ. 5253, Apr. 30, 1928. Two plates of mica, inserted cross-wise in a metallic holder, have grooves on their edges, which hold the resistance wire in the desired position.

Illuminated thermometer with colored segments to indicate different temperature ranges. R. S. WHIPPLE and CAMBRIDGE INSTRUMENT CO., LTD. Brit. 295,893, Jan. 9, 1928. Structural features.

Apparatus for measuring temperatures with an electric-resistance thermometer. G. P. KULBUSCH and A. M. KALININ. Russ. 5254, Apr. 30, 1928. A modified Wheatstone bridge is specified.

Temperature-control system for condensers. CHARLES L. WARE. U. S. 1,706,719, March 26.

Thermopile. WILLIAM H. THORPE. U. S. 1,706,419, March 26. A portion of the wire forming a plurality of turns of Cu wire is protected by cement and the exposed portion of the wire is then subjected to a reagent such as S vapor, which will form a product of altered elec. conductivity.

Filters. ERNST DIEPSCHLAG. Fr. 645,895, Dec. 19, 1927. Filters of metallic gauze with fine pores are made by applying mechanically or electrolytically to the gauze a metallic ppt. in the form of extended crystals.

Testing filters. AC SPARK PLUG CO. Fr. 646,067, Dec. 22, 1927. A pipe offering a greater resistance to the flow of liquid than the filter when properly working leads to a measuring instrument whereby the pressure applied to the liquid entering the pipe is compared with the resistance offered by the filter to the flow of liquid.

Rotating drum filter. JEAN B. VERNAY. Fr. 646,913, Jan. 10, 1928.

Gravity oil filter. WILLIAM S. HARDEN and ROY D. DULEY. U. S. 1,706,228, March 19. Structural features.

Filter for beverages, etc. JOHN PALMER. U. S. 1,706,250, March 19. Structural details of a fabric filter of the siphoning type are described.

Air-filtering device suitable for use on tanks holding gasoline, etc. EARTHEN H. CAMFIELD. U. S. 1,706,772, March 26. Structural features.

Device for separating moisture from air. JENS A. PAASCHE. U. S. 1,706,676, March 26. Structural features. The air is passed through a mass of small stones or pebbles.

Apparatus (with tubular filter elements) for filtering solutions from ore slimes or other liquids. RANDOLPH W. DIAMOND (to Genter Thickener Co.). U. S. 1,706,400, March 26. Structural features.

Apparatus for separating oil and water or other liquids by gravity. BERNARD D. COMYN. U. S. 1,707,077, March 26. Structural features.

Apparatus for effecting separation of oil, gas and water by gravity and centrifugal action. JULIUS E. KOBERNIK (to Newton Process Mfg. Co.). U. S. 1,705,669, March 19. Structural features.

Magnetic separator. A. DAVIES. Brit. 295,417, May 5, 1927. Structural details.

Filter plates, rings, etc. "HANSA" FILTERWERKE M. B. H. Ger. 471,305, Apr. 10, 1926. In prepg. thin filter plates, rings, etc., from materials such as kieselguhr, a series of superposed plates or rings is molded from the damp material, each being sepd. from that above or below by a sheet of combustible material, e. g., paper or fabric, and the bottom one resting on a refractory base, e. g., chamotte. The structure is then calcined.

Cathode discharge tubes. NAAMLÖÖZE VENNOOTSCHAP PHILIPS' GLOEILAMPEN-FABRIEKEN. Fr. 646,662 and 646,663, Dec. 31, 1927.

Covering the cathode in cathode tubes with a layer of active material. ELECTRO-TECHNICAL TRUST OF WEAK CURRENTS. Russ. 4666, Feb. 29, 1928. The metallic base of the cathode is covered electrolytically with a layer of a porous metal like that of the cathode without using a binder. Then the electrode is impregnated with active material.

Electric vacuum-tube discharge-device. A. W. HULL (to British Thomson-Houston Co., Ltd.). Brit. 295,702, Aug. 19, 1927. Flow of electrons between a cathode and an anode is controlled by subjecting to a varying degree of illumination an insulated control electrode carrying a layer of light-sensitive material, which may comprise a helix of quartz or optical glass coated with Cs. The filament cathode is of W coated with Cs. At least part of the inner surface of the container is coated with alkali metal, or, instead of alkali metal, there may be used substances such as Mg or Ca sensitive only to ultra-violet light, or substances such as BaO or compds. of S sensitive to infra-red light. Various structural details are described. Cf. C. A. 22, 3810.

Thermionic valves or vacuum tubes. LOEWE-AUDION GES. and B. WIENECKE. Brit. 296,005, Aug. 22, 1927. Electrode supports and other glass parts which are exposed to high temps. are made of glass such as Jena-instrument glass, which is a good insulator at such temps. Various structural details are described.

High-emission lamps. SIEGMUND LOEWE. Fr. 646,813, Jan. 7, 1928. Deposition of Mg on the elements is prevented by an arrangement of screens.

Selenium light-sensitive cell. S. M. MOSHKOVICH. Russ. 5295, May 31, 1928. One or more mol. layers of Se with alternate layers of another metal are pptd. by sublimation between two ring-shaped electrodes on the inner walls of an evacuated glass container covered previously with a semitransparent layer of a metal.

Air cooler for drying chambers. N. I. KOSTROMIN. Russ. 5466, May 31, 1928.

Apparatus for drying granular materials such as coal. LUDWIG HONIGMANN and FRIEDRICH BARTLING. U. S. 1,705,617, March 19. The material is dried by a current of heated gas.

Apparatus for drying paints, "chemicals" or other materials in currents of heated air. DAVID S. BAKER. U. S. 1,706,993, March 26.

Air-circulating system for drying paints, varnishes, etc., in a tunnel kiln. KARL A. WEBER (to Weber Showcase & Fixture Co.). U. S. 1,706,554, March 26.

Apparatus for spray desiccation of milk, etc., or for mixing substances by circulation and spraying in a mixing tank. ERNEST E. LINDSEY. U. S. 1,705,822, March 19.

Apparatus for mixing different liquids in desired proportions. HERMANN KAUFERTZ. U. S. 1,707,058, March 26.

Apparatus for mixing various liquid and solid materials. PAUL LENART. U. S. 1,706,176, March 19.

Gas generator. GUSTAV SCHÖNBAUM. Fr. 646,307, Dec. 3, 1927. The necessary steam is taken from a water jacket surrounding the generator, and the mixt. of air and steam is heated in the space between the generator and the lower part of the jacket.

Apparatus for gas analysis. SOCIÉTÉ L'AIR LIQUIDE (SOC. ANON. POUR L'ÉTUDE ET L'EXPLOITATION DES PROCÉDÉS G. CLAUDE). Fr. 646,236, May 11, 1927. An app. is described in which gas to be analyzed is passed from a buret to an absorption vessel and back again by automatic cam devices operated by a motor; the amt. of gas absorbed is recorded by a float on the liquid in a vessel connected to the absorption vessel, an indicator making a trace on a rotating cylinder.

Apparatus (with fixed and rotary annular perforated disks and radial liquid jet nozzles) for cooling and purifying gases. FRANCIS G. INGLIS. U. S. 1,707,163, March 26. Structural features.

Valves and valve-control devices for gas purifiers. H. H. HOLLIS. Brit. 295,269, April 8, 1927. Structural features.

Gas washer of the spray wheel type. E. M. BASSLER. Brit. 296,159, June 28, 1927.

Apparatus for atomizing liquids for washing gases, etc. WILHELM A. BODAMER and OSCAR E. RAMUZ. Fr. 645,983 and 645,984, Dec. 21, 1927.

Propeller-blade device for atomizing liquids with gases in reaction chambers. H. PETERSEN. Brit. 295,856, Oct. 10, 1927.

Apparatus for subjecting gases, liquids, etc., to dark electric discharges. C. EPNER. Brit. 296,019, Aug. 23, 1927. The electrodes consist of liquids boiling above 100° and the liquids may be circulated and used for maintaining the substance under treatment at desired temp. The vessels contg. the electrode liquids are preferably made

from or coated with a material, the dielectric, properties of which are not affected by temp. changes, *e. g.*, quartz.

Gaseous conduction device of the point-to-plate discharge type. WILLIAM B. GERO (to Westinghouse Lamp Co.). U. S. 1,707,002, March 26. The anode is formed at least in part of porous misch metal.

Apparatus for mixing gases in regulated proportions. I. G. FARBERIND. A.-G. Brit. 296,063, Aug. 24, 1927.

Electromagnetic gas-pressure regulator. ALLGEMEINE VERGASUNGS G. M. B. H. Fr. 646,931, Jan. 10, 1928.

Adsorption apparatus for separating gases and vapors. A. GODEL. Brit. 295,504, July 25, 1927. An app. is described suitable for sepg. gases and vapors by selective absorption and for treatment of the absorbent. This app. is a modification of that described in Brit. 267,369 (C. A. 22, 1221).

Apparatus for treating solids with gases. AKTIESELSKAPET NORSK STAAL (ELEKTRISK-GAS-REDUKTION) and E. EDWIN. Brit. 295,999, Aug. 22, 1927. An app. is described suitable for use in roasting operations, for reduction by means of gases and for the treatment of gas mixts. by solid catalysts. It comprises a shaft-like chamber formed with superposed compartments through which the gas is passed from top to bottom of the app. The app. is mounted so that it can be raised and lowered in such a manner as to allow replacement of one of the compartments (which are detachable from each other) with another freshly charged compartment as desired for continuation of the process.

Continuous annealing furnace. AKTIEN GESELLSCHAFT BROWN, BOVERI ET CIE. Fr. 646,352, Dec. 26, 1927.

Induction furnace for fusing or annealing. EMILE F. RUSS. Fr. 646,828, Jan. 7, 1928.

Crucible furnace. WILHELM RITTERSHAUSEN. Ger. 471,280, Feb. 13, 1926. Improvements are described in a furnace of the kind in which the crucible is tiltable and remains heated while discharging its contents.

Bakery furnace. HENRI VEAUGEOIS. Fr. 645,944, Dec. 20, 1927.

Regulator for air and gas in gas furnaces. SOC. DES GRILLES ET GAZOGÈNES SAUVAGEOT. Fr. 646,072, Dec. 22, 1927.

Coal-dust burner. STEIN- UND THON-IND.-GES. "BROHLTHAL." Ger. 471,330, Apr. 20, 1927. The burner is of the kind in which the fuel forms a whirling conical cloud in the combustion chamber.

Burner for powdered fuel. CHRISTA RUHE GEB. FRANKE, GERTRUD FRANKE GEB. MOHNICKE and WOLFGANG FRANKE. Ger. 471,404, Apr. 15, 1925. The fuel and air are drawn together through tubes into the combustion space.

Gas burner. CARL E. METHUDY (to Methudy Automatic Lighter Co.). U. S. 1,706,070, March 19. Structural details.

Gas burner. C. OLIVIER. Brit. 295,738, May 18, 1927. Structural features.

Gas-burner regulating device. STOVES, LTD., and W. J. CHARLES. Brit. 296,142, June 7, 1927.

Automatic cut-off for gas-burner valves operating when the flame becomes extinguished. R. LANGER. Brit. 295,207, March 29, 1928.

Oil burner. PHILIPP SCHEFFEL. Ger. 471,326, Apr. 7, 1927. The fuel trickles down rods, which pass loosely through the bottom of a superposed fuel container and so are easily cleaned. The air for combustion passes round the rods.

Oil burner with automatic cut-off operative on failure of the air supply. G. KINSMAN (to Caloril Burner Corp.). Brit. 295,707, Aug. 18, 1927. Brit. 295,708 also relates to oil-burner construction.

Mechanical oil burner. A. D. SEKRETOV. Russ. 5523, May 31, 1928. A modified Gordeyev-type oil burner.

Mechanical oil burner. M. A. TREIER. Russ. 5289, Sept. 15, 1924. Mechanical features.

Apparatus for burning crude oil under steam boilers. T. B. LETTER. Russ. 5403, May 31, 1928.

Oil-burner control. WILLIAMS OIL-O-MATIC HEATING CORP. Ger. 471,097, June 10, 1926. The pump supplying the fuel is automatically adjusted in accordance with the pressure or the temp. in a boiler heated by the burner. Corresponds to Brit. 273,458.

Safety controls for oil burners. WILLIAMS OIL-O-MATIC HEATING CORP. Ger. 471,098, June 6, 1926, 471,099, Aug. 14, 1926 and 471,100 Mar. 11, 1927. The motor supplying the fuel is automatically controlled by temp.-sensitive devices. Corresponds to Brit. 276,095, 277,785 and 280,771 (C. A. 22, 3071), resp.

Safety control for oil-heated boiler. WILLIAMS OIL-O-MATIC HEATING CORP. Ger. 471,198, Oct. 17, 1926. A float arranged in a chamber communicating with the water space actuates a switch controlling the elec. circuit to the burner when the water falls below a predetd. level. Corresponds to Brit. 268,670.

Safety system for burning fuel oil under pressure. ROSS M. G. PHILLIPS (to Harry V. Whipple). U. S. 1,706,704, March 26. Numerous mech. details are specified.

Safety device for mazout burner. SOC. ANON. DES CHANTIERS ET ATELIERS DE SAINT-NAZAIRE (PENHOËT). Fr. 646,361, Dec. 26, 1927.

Air distributor for mazout burner. SOC. ANON. DES CHANTIERS ET ATELIERS DE SAINT-NAZAIRE (PENHOËT). Fr. 646,151, Dec. 24, 1927.

Attachment for a "Primus" kerosene-vapor burner to widen and direct the flame. V. A. TRAVNIKOV. Russ. 5376, May 31, 1928.

Heat exchanger, especially for preheating air for combustion. AKTIEBOLAGET LJUNGSTRÖMS AANGTURBIN (Fredrik Ljungstrom, inventor). Ger. 471,199, Nov. 25, 1925.

Concentric tube heat-exchange apparatus. ROYLES, LTD., and A. G. ROYLE. Brit. 295,245, May 6, 1927.

Multiple chamber continuous kiln. A. L. GELDENS. Brit. 295,867, Nov. 2, 1927.

Heaters for oil refining. A. O. SMITH CORP. Fr. 646,642 and 646,643, Dec. 31, 1927.

Plate-surface air heater. MAURICE LEVRON. Ger. 471,426, Jan. 3, 1926.

Furnace-roof construction. GUSTAV KARREBERG. Fr. 646,125, Dec. 23, 1927.

Means for feeding liquid fuel to burners. FRIEDRICH DECKEL, PRAZISIONS MECHANIK UND MASCHINENBAU. Ger. 471,423, Mar. 26, 1925.

Inclined grate with alternate stationary and moving parts. L. & C. STEINMÜLLER. Ger. 471,424, Feb. 16, 1926. Addn. to 456,005.

Inclined grate with alternate stationary and reciprocating parts. OTTO SCHENK. Ger. 471,402, Apr. 4, 1924. Addn. to 353,154.

Reversing means for regenerative ovens. MORGAN CONSTRUCTION CO. Ger. 471,327, Dec. 15, 1926.

Stone packing material to produce spiral movement in gas-stream passing tubes. BERTHOLD GRÖNHAGEN. Ger. 471,403, Sept. 12, 1925.

Fillers for towers. FRITZ GRAUPNER and REINHOLD KRÜGER. Ger. 471,232, Aug. 25, 1927. Absorption or reaction towers are filled haphazardly with spherical, cube-shaped, cylindrical, etc., fillers, each of which is bored through several times so that each boring intersects other borings at different points within the filler.

Apparatus for the vaporization and concentration of liquids. KARL FRIED. Fr. 646,894, Jan. 9, 1928.

Apparatus for measuring liquid flowing through pipes. V. M. VOLOKHVYANSKI. Russ. 5429, May 31, 1928.

Arrangement for directing the flow of cooling media in reaction coils, transformers and similar apparatus. I. A. KRAVTZOV. Russ. 5386, May 31, 1928.

Scales for automatic weighing of liquids. N. E. BEREZOVSKII. Russ. 5425, May 31, 1928.

Apparatus for extracting oil from solids used in its purification. PHILIP L. FAUTH. Fr. 646,750, Jan. 6, 1928.

Apparatus for centrifugal treatment of hydrocarbon oils or other liquids. HANS O. LINDGREN (to DeLaval Separator Co.). U. S. 1,705,934, March 19. An app. is described in which materials such as petroleum oils are discharged from a centrifugal app. in finely divided form into a collecting vessel where they may be subjected to a vacuum to sep. any entrained gas.

Apparatus for preparing extracts by steeping. W. BUSS. Brit. 295,869, Nov. 9, 1927.

Apparatus (with a screw conveyor) for feeding and measuring granular or pulverulent materials. ARTHUR W. HEYMAN. U. S. 1,706,292, March 19.

Gas-tight bearing suitable for use in motor-driven gas compressors, etc. CHARLES P. EISENHAEUER (to The Duro Co.). U. S. 1,706,776, March 26. Structural features.

Catalytic apparatus. COMPAGNIE NATIONALE DE MATIÈRES COLORANTES ET MANUF. DE PRODUITS CHIM. DU NORD RÉUNIES ÉTABLISSEMENTS KUHLMANN. Fr. 646,264, May 13, 1927. An app. is described for the catalytic oxidation of org. compds., particularly aromatic hydrocarbons, in which the catalyst is spread in a thin layer on a good conductor of heat, e. g., Al, with which the gases come in contact before entering the catalyst chamber.

Alcohol-recovery apparatus for baking ovens. OTTO HELLER. Ger. 471,086, Feb. 26, 1926.

"Steam storer" or "heat accumulator" comprising a pipe coil embedded in concrete. GOTTLIEB HOLTHAUS (to Siemens-Schuckertwerke A.-G.). U. S. 1,705,975, March 19. A device is specified suitable for utilizing waste heat of blast-furnace gas for generating steam at a pressure above 225 atm.

Apparatus for applying lead sheathings to cables. SIEMENS BROS. & CO., LTD., and E. R. HUBBARD. Brit. 295,416, April 13, 1927.

Acid-proof container. JOSEF GLATZ. Swiss 127,776, July 13, 1927. An acid-proof reinforced-concrete container has a protecting covering; it also has plates with freedom for expansion due to hot liquids.

Alarm device for indicating heating of oil-insulated electric transformers, etc. GEORGE D. CLARK (to Westinghouse Elec. & Mfg. Co.). U. S. 1,705,715, March 19.

Thermal cut-out device to prevent overheating of electrically heated apparatus. W. EDWARDS. Brit. 295,796, June 24, 1927.

Thermostat. S. P. SHOROKHOV. Russ. 5520, May 31, 1928.

Thermostatic valve. K. AIRD and R. & A. MAIN, LTD. Brit. 296,129, May 27, 1927. Structural features.

Thermostatic control device for electric circuits. ABRAHAM J. KUSEL and GEORGE W. GAIL (to Kulair Corp.). U. S. 1,706,890, March 26. Structural features.

Thermostatic device for controlling electric circuits. ALFRED W. BURKE (to Burke Controller Corp.). U. S. 1,707,185, March 26.

Thermostatic device for control of electric circuits. EDWARD M. CLAYTOR (to Westinghouse Elec. & Mfg. Co.). U. S. 1,705,716, March 19.

Thermostatic device for control of electric circuits. VIRGIL E. DUEMLER and GEORGE R. KOELN (to Electrol, Inc.). U. S. 1,706,057, March 19. Structural features.

Thermostatic regulator for electric ovens, etc. HAROLD E. WHITE (to Westinghouse Elec. & Mfg. Co.). U. S. 1,705,694, March 19.

Thermostatic gas regulator for water heaters. FRANK W. SHUELL, ELMER E. LEDBETTER and THOMAS J. TOBEY (to Everhot Heater Co.). U. S. 1,705,787, March 19.

Thermostatic control device for valves of gas burners. RADIATION, LTD., and H. J. YATES. Brit. 295,823, Aug. 2, 1927.

Thermostatic combustion-control apparatus. LOUIS HOEDT. U. S. 1,707,012, March 26.

Thermostatic alarm device suitable for use as a fire alarm. G. ROWAN. U. S. 1,705,837, March 19. Structural features.

Thermostatic valve for controlling flow of liquid in engine cooling systems. NELSON J. QUINN. U. S. 1,705,498, March 19. Structural features.

Thermostatic device for control of air conditioning systems. JOHN M. LARSON (to National Regulator Co.). U. S. 1,705,527, March 19. Structural features.

Thermostatically controlled apparatus for mixing liquids such as water at different temperatures to attain a mixture of desired temperature. ROBERT S. BLAIR. U. S. 1,707,109, March 26.

2—GENERAL AND PHYSICAL CHEMISTRY

FREDERICK L. BROWNE

Christian Friedrich Schönbein. I. Life and character. RALPH E. OESPER. Univ. of Cincinnati. *J. Chem. Education* 6, 432-40(1929). E. H.

High-school chemistry and the student's record in college chemistry. IRA D. GARARD and THALIA B. GATES. *J. Chem. Education* 6, 514-7(1929). E. H.

The one college chemistry course for freshmen. C. A. BUEHLER. Univ. Tenn. *J. Chem. Education* 6, 510-3(1929).—A study of the grades made by all students taking one general chemistry course at the University of Tennessee shows that: (1) Students with high-school chemistry make a better record during the first part of the work and they always stand a better chance of getting an A or B. (2) Students with no high-school chemistry have the better record during the latter portion of the work. Several suggestions are given to account for this superiority on the part of the untrained students. E. H.

The story of copper. J. W. HOWARD. *J. Chem. Education* 6, 413-31(1929).—A review especially of the metallurgy of Cu, with a brief account of its history, occurrence, properties and uses. E. H.

Some illogical ideas that persist in elementary chemistry. CECIL V. KING. Washington Square College, N. Y. *J. Chem. Education* 6, 65-71(1929).—Exception is taken to the treatment often accorded to the terms (a) burn, combustion, support combustion; (b) oxidation and reduction; (c) classification of chem. reactions; (d) nascent gases.

W. C. EBAUGH

Multiplicative properties. M. TRAUTZ. Univ. Heidelberg. *Z. angew. Chem.* 42, 89-94(1929).—A lecture discussing additive and multiplicative properties of homogeneous systems of 2 or more components. A *multiplicative property* is a property whose magnitude is a product of corresponding magnitudes for the separate components of the system or for the separate reactants in a chemical reaction. The laws of mass action are based on multiplicative properties.

W. C. EBAUGH

The physical chemist in search of purity in an impure world. ERNST COHEN. Messel Memorial Contribution. *Proc. Roy. Inst. Gr. Britain* 25, Pt. III, 417(1928); *J. Soc. Chem. Ind.* 48, 162-8(1929).—A discussion of metastable forms in terms of white and gray Sn, "explosive Sb," Majorana's effect, thallous picrate, AgI, CdI₂, and sugar. Physical as well as chem. purity is essential for the detn. of physical consts. The powder röntgenograph detn. of d. is probably the most reliable method of insuring physical purity. Const. d. is suggested as another indication.

FOSTER DEE SNELL

Effect of ozone on the temperature of the upper atmosphere. E. H. GOWAN. *Proc. Roy. Soc. (London)* A120, 655-69(1928).—From the abnormally high values obtained for the d. of the atm. calcd. from observations of meteors, Lindemann and Dobson (*Ibid* A102, 411(1922)) concluded that the temp. above 60 km. is of the order of 300° abs. Whipple (*Nature*, 111, 187(1923)), from observations of the zones of audibility occurring at some distance round big explosions, found that near 60 km. a temp. of about 280° abs. was to be expected. A theoretical consideration of the radiative equil. of the upper atm., taking into account the effects with selective absorption, of water vapor and ozone, leads to a region of high temp. in the neighborhood of, and above, 60 km. The equation of equil., considering only vertical radiation, for any layer of air in a non-convective region is $\int R_{\lambda T} d\lambda = \int (X_{\lambda}' + I_{\lambda}' + E_{\lambda}' + S_{\lambda}') d\lambda$, where $R_{\lambda T}$ is the radiation from any layer at temp. T , X_{λ}' and I_{λ}' are the absorbed portions of the atm. radiations from above and below the layer, and E_{λ}' and S_{λ}' are the portions of the terrestrial and solar radiations absorbed in the layer. An analytical soln. of this equation can be found when the coeff. of absorption does not vary with the wave length. When selective absorption is used a graphical soln. is possible, and has been obtained by successive approximation. The results, as regards both temp. and height of the warm region, agree well with those of indirect observations.

B. C. A.

Colorimetric measurements. HANS EGNÉR. *Svensk Kem. Tids.* 40, 197-205(1928).—A survey of appliances for colorimetry with 12 references.

A. R. ROSE

Simplification of laboratory procedure for low-pressure distillation. W. JEZIESKI. *Przemysl Chem.* 11, 528(1927).—When bumping is avoided by slow inlet of air into a liquid being distd. under low pressure the usual screw clamp regulation of the rate of inflow of air may be dispensed with by putting into the rubber tube at the wide end of the capillary another glass tube drawn to a capillary in such a manner that the rubber tube is connected to the wide ends of both capillaries.

A. C. ZACHLIN

Thirty-fifth annual report of the committee on atomic weights. Determinations published during 1928. GREGORY P. BAXTER. *J. Am. Chem. Soc.* 51, 647-54(1929). The work done during 1928 on K, Ti, Cu, Ca, Ba, Ag, Ce, Er, Re, Pb and U is reviewed. The table of at. wts. for 1929 is given in which changes from the 1928 table are made for H, P, S, Ba, Ce, Er, K, Ra, Th and U.

E. SCHOTTE

The specific heat of tungsten between 90° and 2600° abs. C. ZWIKKER AND G. SCHMIDT. *Natuurk. Lab. N. V. Philips Gloeilampenfabrieken, Eindhoven.* *Physica* 8, 329-46; *Z. Physik* 52, 668-77(1928).—The principle of the method used at low temp. is Eucken's (*C. A.* 3, 2898). A Pt wire (60 μ , 0.112 g.) is coiled around a W block (17.457 g.), insulated from it by paraffin paper. Around the Pt another layer of paper is held together by W wire closely wound so as to enclose all Pt in W (paper wt. 0.062 g., W total 18.802 g.). The Pt serves both as resistance thermometer and as heating element. The whole unit was inserted in a vacuum bulb cooled outside by liquid O. After the temp. of the W has decreased slowly to that of the cooling medium the bulb is pumped out. The temp. of the metal then rises slowly from conduction of heat through the lead-in wires. This rise is observed for some time; then a heating current is sent through the Pt and the slow rise again followed. From the rise in temp. and the energy used the desired sp. heat is calcd. The values found were 3.6 cal. per g. atom (C_p) at 92° abs. to 4.6 at 140° abs., 5.9 at 290° abs.; they can fairly well be represented by a Debye curve with $\theta = 310$ (the exptl. values near 300° are too high). For C_p at

higher temp. two methods were used. The first one consists in raising at a time t_0 the current through an incandescent W wire at const. temp. Temp. and voltage of the wire increase and the time t_1 is observed when a certain predetd. voltage is reached.

From $I^2R = W + C(dT/dt)$ (W is radiation) it follows that $t_1 - t_0 = c \int_T^{T+\Delta T} \frac{dT}{(I^2R - W)}$.

I^2R and W are known from previous work as functions of T (T itself is found from the voltage), so that C may be evaluated by graphical integration. The time was registered automatically by a relay system and band recorder. For the measurements wires of 863μ (1460° to 2200°) and 300μ (600° to 1400°) were used. The exptl. values are averages between measurements with increased and decreased currents. The results for C_p were 6.57 at 600° abs., slowly rising to 6.9 at 1225° , 7.5 at 2055° , and 7.9 at 2220° abs. The second high temp. method is the one of variation in electron emission. The amplitude of the variation in temp. of an incandescent filament fed by a. c. $\theta = \frac{2V\eta}{C_p d \nu}$ (V is at. vol., η radiation per sq. cm., d diam. of wire, ν frequency of current). As well as other temp. functions the electron emission shows a similar variation which can be easily measured. For the purpose between 1600° and 1800° abs. the W was coated with Th, between 1200° and 1400° abs. with Ba and between 2220° and 2600° abs. the W was left bare. A special generator for pure sinusoid low-frequency a. c. was constructed. Several corrections in the calcns. due to time lag are discussed and were applied; also for asymmetry of the amplitude and for temp. difference in and outside the wire. Below a 100μ diam. the latter effect is negligible. The results were (40μ wire, frequency 50) C_p from 8.0 to 8.35 between 2210° and 2521° abs., from (119μ wire, 7.3 to 12.8 frequency) 7.4 to 7.6 between 1610° and 1873° abs., from (51.7μ wire, 975 to 13.9 frequency) 7.0 to 7.2 between 1150° and 1333° abs. The final table gives for C_p in cal. per g. atom at abs. temps. of 100, 200, 300, 600, 900, 1200, 1500, 1800, 2100, 2400, 2700 and 3000: 3.77, 5.32, 5.90, 6.23, 6.57, 6.90, 7.23, 7.56, 7.89, 8.22, 8.56, 8.89, for C_v (the χ , compressibility, used is Bridgman's at low temps, Geiss' elasticity-temp. relation at high temp.) 3.77, 5.30, 5.87, 6.15, 6.44, 6.71, 6.96, 7.18, 7.36, 7.50, 7.62, 7.70. At high temps. C_v seems to approach a value of 8 and does not run up at increasing rate as was expected.

B. J. C. VAN DER HOEVEN

Absorption of ultra-violet light by liquid carbon dioxide. G. HARIG. Leipzig Univ. *Physik. Z.* 30, 8-20(1929).—H. develops a method to det. quantitatively the absorption by thin layers of gases in the liquid state under high temp. and pressure. The light source is a Cd arc, which is especially suited to ultra-violet work. A large quartz spectrograph by Hilger, London, is used. The method for measuring pressures is described in detail. H. found oil to dissolve in liquid CO_2 and describes his method of obtaining very pure CO_2 by distn. Liquid CO_2 in ultra-violet light absorbs 1000 times more strongly than gas at the same pressure. This strong absorption also remains in the supercritical state but disappears quickly with rise in temp. in the region of the inflection points of supercritical isotherms and isobars. The absorption coeff. is calcd. at $\lambda = 2552 - 2195$ A. U. The absorption may be considered as due to a broad band at $\lambda = 2265$ A. U. and to a second band, more compact, whose max. is about $\lambda = 2435$ A. U.

S. L. B. ETHERTON

Dielectric constants and absorption indices of several alcohols for short electric waves. SAN-ICHIRO MIZUSHIMA. Tokyo Imp. Univ. *Proc. Imp. Acad.* 5, 15-6 (1929); cf. *C. A.* 22, 4348.—Dielec. consts. and absorption indices of the following alcs. are reported for the λ indicated, at 20° intervals of temp. from 60 to -60° , MeOH, $\lambda 58.0$ cm.; PrOH, iso-BuOH, AmOH, $\text{C}_2\text{H}_5(\text{OH})_2$, $\lambda 57.8$ cm. The region of anomalous dispersion is shifted toward longer wave lengths when the temp. is lowered, as well as when a mol. becomes more complicated for a homologous series; this agrees with Debye's dipole theory of anomalous dispersion. The results for $\text{C}_2\text{H}_5(\text{OH})_2$ are not in accord with the dipole theory.

C. J. WEST

Electric dipole moments of organic molecules. II. J. ESTERMANN. *Phys. Chem. Inst., Hamburg Univ. Z. physik. Chem., Abt B*, 1, 422-6(1928); cf. *C. A.* 23, 317-8.—Measurements of μ (dipole moment) of certain org. comds. seem to indicate that *o* or *p* substitution does not necessarily affect the dipole moment to a marked degree; likewise the length of the side-chain does not radically affect this quantity. For methyl benzoate $\mu \times 10^{18} = 1.8$; dimethyl phthalate, 2.3; dimethyl terephthalate, 2.2; ethyl benzoate, 1.8; diethyl phthalate, 2.4; diethyl terephthalate, 2.3. $\mu = 0.5 \times 10^{-18}$ for diphenyl ethylene while $\mu = 2.5 \times 10^{-18}$ for benzophenone. W. E. V.

Pyro- and piezo-electricity. A. MEISSNER. *Naturwissenschaften* 17, 25-31 (1929); cf. C. A. 22, 3573.—A review of recent work on this subject, especially on quartz and theories of the structure of the latter. X-ray work has shown the quartz unit cell to consist of 3 SiO_2 mols., the distance a between Si and Si in one plane being 4.89 A. U.; in different planes $c = 5.37$ A. U. From the acoustic vibrations in a disk of quartz cut perpendicular to an elementary axis set up by a high-frequency current applied by 2 electrodes on opposite faces it was found that the proper frequency of the quartz lay at $\lambda = 1160$ and 1665 m. (15 mm. thick). The vibrations are specially strong in 2 directions (causing air currents by rectification effects (C. A. 21, 3825)) at a 46° angle with the optical axis. The wave lengths correspond to max. sound velocities of 7700 and 5400 m. per sec. It is assumed that the 2 planes perpendicular to the disk face at $\alpha = 46^\circ$ are those of largest atom density (Si planes). The same effect is found for all 3 elementary axes. It gives a structure of almost cubical shape for the Si planes with the optical axis along the cube diagonal, the cube being slightly compressed along this axis. This agrees with the 2 dielec. consts. of 4.46 and 4.38 along and perpendicular to the optical axis. From $d = 2.65$ and Avogadro's no. the distance between 2 Si atoms is 3.336 A. U. The distances a and c calcd. for this structure, assuming a 46° angle between optical axis and Si planes, are 4.9 and 5.44 A. U. Between each 2 Si atoms is the center of gravity of two O atoms. The unit cell has 3 SiO_2 . By assuming the same elementary qualities for the unit cell as for the macro-crystal it is shown that the 3 elementary axes are along the diagonals of hexagons of alternate Si and two O (one a little above, the other one below the plane). These hexagon cells of Si_2O_4 are the source of the pyro- and piezo-effects. In disks perpendicular to an elementary axis, i. e. also to the hexagon plane, pressure will push one Si and one O toward the inside, induction of charges on the electrodes will result by the approach of the other two Si and O groups to the opposite electrodes (+ on the side where Si is pushed in, - on the other side). No effect occurs when the electrodes are orientated parallel to an elementary axis. Stress gives the opposite elementary effects. The pyro-effect is explained by outward displacement of the atoms; the electrode on the heated side will become negative if it had a positive piezo-effect (one Si next to it); on cooling it will be positive. An additional assumption made here is that the displacement of Si under the influence of heat is larger than that of two O but smaller than double the two O displacement. The locations of Si and O are const. for each temp. Any no. of times + and - charges can be taken from the electrodes; the moment remains unchanged. About 10 mins. after cooling the pyro-moment will go to reverse values, reaching a max. and coming back to zero after several hrs. It indicates a slow recovery of a distorted state. Heating over 160° causes the pyro-moment to decrease with time to zero, the cond. of the quartz is then high enough to cause the moment to be compensated by electrons from the electrodes, cooling will give a considerable reverse moment, which may last for days in the cold. Of individual quartz pieces the pyro-moment varied in ratio 1:6, of the piezo-moment 1:1.5. Other expts. were made with various materials to obtain non-crystalline piezo-elec. material (C. A. 23, 1546).

New superconductors. W. J. DE HAAS. Kryogen. Inst., Leiden. *Naturwissenschaften* 17, 85-6 (1929).—The suggestion has been made previously that superconductivity (*J. physique* 9, 9 (1928)) is due not only to the electron configuration of the atoms but also to their at. wt. and zero points of energy. Several more metals and their compds. were recently examd. Cu, Ag and Sb, which are not superconductive, with the superconductive Sn, also Bi with Tl. Sb + Sn alloys and Bi + Tl alloys are superconductive. The resistance of Ag_3Sn decreases from 3.4° to 1.3° abs. without super effect. The eutectic alloy of Au and Bi (Bi being below and Au above the 3 superconductive metals Hg, Tl and Pb in at. wt.) was examd. It is superconductive although neither component is superconductive. The alloy has at 2.2° abs. a resistance 0.7 times that at room temp.; at a temp. $1/20$ degree lower the resistance has completely disappeared. The level from which the resistance drops to zero in the Au-Bi alloy is 350 times higher than the corresponding level for Hg, 1000 times higher than that of Pb. At 1.5° abs. neither Au nor Bi shows any sign of superconductivity.

The transfer of matter in the iron arc. H. SCHMICK AND R. SEELIGER. *Physik. Z.* 29, No. 23, 864 (1928).—The decrease in wt. of an Fe cathode is not proportional to the current alone. It depends also on the cooling of the cathode. The whole surface adjacent to the bright spot contributes to the loss which is caused not only by evaporation but also by ejection of droplets.

The behavior of solutions of chromium trioxide upon electrolysis. D. T. EWING, J. O. HARDESTY AND TE HSIA KAO. *Mich. State Col. Mich. Eng. Expt. Sta. Bull.* No. 19, 3-13 (1928).—Solns. contg. 250 g. per l. of Cr_2O_3 were electrolyzed to det. the

effects of temp. and c. d. on the amts. of current used in the deposition of Cr and in the generation of H_2 . The percentage of current expended in the deposition of Cr increased with increased temp. and c. d. while the percentage of current used in generating H_2 decreased.

C. L. READ

Examination of the microcrystals of calcium carbonate in molluscan shells by means of x-rays. I. J. TSUTSUMI. *Mem. Coll. Sci. Kyoto Imp. Univ.* 11, 217-21 (1928).—The shell of *Atrina japonica* consists of 3 layers, the middle or prismatic one having a columnar structure. This layer is shown by x-ray analysis to consist of calcite crystals the principal axes of which coincide with those of the columns. B. C. A.

Fibrous structure in metals deposited by the difference of electrolytic solution pressures. S. TSUBOI. *Mem. Coll. Sci. Kyoto Imp. Univ.* 11, 271-7 (1928).—Ag deposited on Cu from $AgNO_3$ solns. forms flat, acicular crystals which have a fibrous structure. The fiber axis lies in the [110] direction, and makes an angle of 30° with the acicular axis, the direction of growth being nearly parallel to the [112] direction. The [111] plane is nearly parallel to the flat surface of the crystal in most of the fibers.

B. C. A.

Remarks concerning the work of W. Dilthey and E. Hölderhoff: Silicic acids. H. STAUDINGER. *Ber.* 62B, No. 2, 442 (1929).—S. claims priority for certain theories of structure of fibrous substances, attributed by D. and H. (*C. A.* 23, 1585) to K. H. Meyer.

T. P. KELLER

The crystal structure of potassium chloroplatinate. F. J. EWING AND LINUS PAULING. *Calif. Inst. of Tech. Z. Krist.* 68, 223-30 (1928). (In English.)—Spectral and Laue photographs show K_2PtCl_6 to have the K_2SnCl_6 type of structure with $a = 9.73$ A. U. and $u = 0.240 \pm 0.005$. The value of $u = 0.16$ reported by Scherrer and Stoll (*C. A.* 16, 3239) is incorrect.

L. S. RAMSDELL

The crystal structure of ethylammonium chlorostannate. R. W. G. WYCKOFF. *Z. Krist.* 68, 231-8 (1928). (In English.)—Laue and spectral photographs of crystals of $(NH_4C_2H_5)_2SnCl_6$ and $(NH_4C_2H_5)_2PtCl_6$ show that each has a hexagonal unit cell contg. 1 mol. For the first, $a = 7.24$ and $c = 8.41$ A. U.; less accurate values for the second are $a = 7.13$ and $c = 8.53$ A. U. The at. arrangement is from space group $3D_2-3$, with Sn (Pt) at 000; Cl at $u\bar{u}v$, $2\bar{u}\bar{u}v$, $u2u$, $u\bar{u}v$, $2u\bar{u}v$, $\bar{u}2\bar{u}v$; N at $2/3, 1/3, \bar{v}$; and C at $1/3, 2/3, \bar{v}$, $2/3, 1/3, v$, $1/3, 2/3, v$, $2/3, 1/3, \bar{v}$. For the chlorostannate u and v have the values 0.16 and 0.17.

Atomic distances in mixed crystals of gold and copper. A. E. VAN ARKEL AND J. BASART. *Z. Krist.* 68, 475-6 (1928).—Interat. distances are detd. for a series of mixed crystals of Au and Cu, and compared with theoretical values.

L. S. RAMSDELL

The crystal structure of *cis*-ethylene oxide-dicarboxylic acid. A. REIS AND W. SCHNEIDER. *Z. Krist.* 68, 586-94 (1928).—This compd. is monoclinic prismatic, with the axial ratio 3.118:1:0.998; $\beta = 91^\circ 10'$. The symmetry is that of space group C_{2h}^6 , and there are 8 mols. of $C_4H_4O_6$ in the unit cell, which has the dimensions $a = 21.50$, $b = 6.90$ and $c = 6.89$ A. U.

L. S. RAMSDELL

The crystal structures of indigo and fumaric acid. A. REIS AND W. SCHNEIDER. *Tech. Hochschule Karlsruhe. Z. Krist.* 68, 543-66 (1928).—Indigo is monoclinic prismatic and crystallizes in needles elongated parallel to the b axis. The axial ratio is 1.897:1:1.741, $\beta = 107^\circ 30'$. The space group is C_{2h}^5 and there are 2 mols. of $C_{16}H_{10}O_2N_2$ in the unit cell with the dimensions $a = 11.00$, $b = 5.8$ and $c = 10.09$ A. U. Fumaric acid is monoclinic prismatic, with axial ratio 0.503:1:0.438; $\beta = 111^\circ 5'$. The space group is also C_{2h}^5 , and there are 6 mols. of $C_4H_4O_4$ in the unit cell in which $a = 7.60$, $b = 15.11$ and $c = 6.61$ A. U.

L. S. RAMSDELL

The crystal structure of pentaerythritol tetraacetate. H. MÖLLER AND A. REIS. *Z. Krist.* 68, 385-6 (1928).—A new interpretation of the results (cf. *C. A.* 22, 2089) leads to a revised structure in agreement with that of Knaggs (cf. *C. A.* 22, 3073).

L. S. RAMSDELL

The crystal structure of the butyl-, amyl-, hexyl- and heptyl-ammonium halides. STERLING B. HENDRICKS. *Z. Krist.* 68, 189-203 (1928). (In English.)—The crystal structures of the chlorides, bromides and iodides of the above compds. were detd. The space group is $4D-2$, $4d-3$, $4Di-7$, $4c-1$, $4e-1$ or $4C-1$. The structures are all similar to that of NH_4MeI (cf. *C. A.* 22, 2861). At. positions and parameters are given. The C atoms

of the hydrocarbon groups have a colinear configuration, which suggests modification of the present accepted interpretation for long-chain aliphatic compds. L. S. RAMSDALL

An investigation into the structure of cesium and ammonium sulfates. WM. TAYLOR AND T. BOYER. *Mem. Proc. Manchester Lit. Phil. Soc.* 72, 125-37(1927-8).—The space group of the isomorphous sulfates of Cs and NH_4 was detd. by x-ray investigation to be V_h^{16} . The dimensions of the unit cell are for Cs_2SO_4 — $a = 6.24$ A. U., $b = 10.92$ A. U., $c = 8.22$ A. U. and for $(\text{NH}_4)_2\text{SO}_4$ — $a = 5.98$ A. U., $b = 10.62$ A. U., $c = 7.78$ A. U. Four mols. are contained in the unit cell. From a study of the intensities of x-rays reflected from the crystals, positions are assigned to the constituent atoms which appear to give the best general agreement between observed and calcd. values of the sum of the scattered amplitudes. Crystals of the 2 compds. have very similar structures.

H. STORRTZ

The form of the central carbon atom in pentaerythritol tetraacetate as shown by x-ray crystal analysis. I. ELLIE KNAGGS. *Proc. Roy. Soc. (London)* A122, 69-76 (1929); cf. C. A. 22, 3073.—Pentaerythritol tetraacetate crystallizes in the tetragonal bipyramidal class; the crystals are built on the Bravais lattice Γ , and the space group C_{4h}^4 ; there are 2 mols. per unit cell, which has the dimensions 11.98×5.47 A. U. The mols. possess a 4-fold alternating axis of symmetry. A probable structure is suggested from which it follows that the symmetry of the central C atom may be tetrahedral although some slight departure from tetrahedral symmetry is possible.

J. B. AUSTIN

Melting curve of hydrogen to 245 kg./sq. cm. W. GULIK AND W. H. KEESOM. *Proc. Acad. Sci. Amsterdam* 31, 1059-60(1928).—See C. A. 23, 1537. In the abstract referred to g. is incorrectly used instead of kg.

F. C. M

The production and uses of tantalum. G. MALCOLM DYSON. *Chem. Age (London)* (Monthly Met. Section), 20, 18-9(1929).

E. H

X-ray studies of the binary systems of iron with phosphorus, arsenic, antimony and bismuth. GUNNAR HÄGG. Univ. Stockholm. *Z. Krist.* 68, 470-2(1928).— Fe_3P has a body-centered tetragonal lattice, with $a = 9.090$ and $c = 4.446$ A. U. The space group is probably S_4^2 . There are 8 mols. in the unit cell. Fe_3P is hexagonal, with symmetry D_{3h} as shown by Laue photographs. The unit cell contains 3 mols. and has the dimensions $a = 5.852$ and $c = 3.453$ A. U. Additional P introduces new lines, probably corresponding to FeP , but no structure was detd. for this compd. Displacement of the Fe lines indicates that about 5% of As is sol. in α -Fe at room temp. The results with Fe_3As may indicate a tetragonal cell, containing 4 mols., with $a = 5.129$ and $c = 5.973$ A. U., but this is questionable. FeAs is orthorhombic, and 4 mols. are in a cell with $a = 3.366$, $b = 6.016$, and $c = 5.428$ A. U. FeAs has a modified NiAs structure. Repeated trials gave no evidence of a compd. Fe_3As_2 . The x-ray pattern indicates that about 7% of Sb is sol. in α -Fe at room temp. Compns. from Sb 63.5 to 65.5% are homogeneous, with a NiAs type of structure, but FeSb corresponds to 59.25% Sb. FeSb is orthorhombic. The unit cell contains 2 mols. and has $a = 3.189$, $b = 5.819$ and $c = 6.520$ A. U. The space group is V_h^{12} and the structure is analogous to that of marcasite, FeS_2 , with Fe atoms at 000 and $\frac{1}{2}, \frac{1}{2}, \frac{1}{2}$, and Sb at $ou\bar{v}$; $ou\bar{v}$; $\frac{1}{2}, u + \frac{1}{2}, v + \frac{1}{2}$; $\frac{1}{2}, \frac{1}{2} - u, \frac{1}{2} - v$, where $u = 0.177$ and $v = 0.354$. In the system Fe-Bi no solid soln and no compds. were found.

L. S. RAMSDALL

The vapor density of steam. C. S. MARTIN, J. E. DAY AND W. L. EVANS. *J. Chem. Education* 6, 107-8(1929); cf. C. A. 18, 3137.—Improvements in manipulative details, better insulation with asbestos to prevent condensation, etc., are suggested in order to enable a student to det. the mol. wt. of H_2O with greater accuracy. W. C. E

Measurement of the time of adherence by entrainment experiments. P. CLAUSSING. *Natuurk. Lab. N. V. Philips Gloeilampenfabrieken, Eindhoven. Physica* 8, 289-304 (1928); cf. *Dissertation, Leiden*, 1928.—Previous expts. were improved (Holst and C. A. 20, 1737) and a new method was devised to measure the time during which a mol. adheres to a wall after impact. The same method allowed measurement of the coeff. of accommodation of metal vapors on walls. The adherence period τ is the reverse of the probability w of evapn. of the adsorbed mol.; at a time t , reasonably long, the no. of molecules adsorbed per sq. cm. is $a = \nu\tau$ for ν the d. of incidence. For small ν (i. e. low pressure) this equation represents an adsorption isotherm. From Frenkel's theory (C. A. 18, 3302) is derived an estimate of τ as dependent on temp. $\tau = 2.84 \times 10^{-13} \cdot 10^{10}/RT$ for Cd mols. on a layer of picein. For Cd on Ag the expts. of Estermann give (C. A. 19, 3211) at $T = 200$, $\tau = 3.7 \times 10^{-11}$ whereas a value of 2.9×10^{-11} is derived from comparison with the previous results on picein. The very poor agreement is evidence of the imperfection of the present theory. A beam of metal vapor from a furnace orifice

(0.2 cm.) enters a tube drilled in one side of a large metal body and terminating after a path of 3.2 cm. in a narrow opening (0.030 cm.). The beam impinges on the surface of a revolving plate which moves rapidly over the opening. Mols. evapg. from the plate condense again on the face of the metal body (plate and face are parallel; the metal body, brass, is well cooled). The entire app. is *in vacuo*. For a shift δ of the ppt. on the brass away from the narrow exit opening due to momentum of the molecules the relation is derived $\tau = (\Delta - \delta)/Z.2\pi q$ in which Δ is the measured distance between center of gravity of the ppt. and the center of the orifice, Z the no. of revolutions of the plate per sec., q the distance (1.90 cm.) of the orifice to the center of rotation of the plate. Under the exptl. conditions the accuracy in τ was 0.4×10^{-6} sec. For the revolution of the plate a magnetic field of 500 cycles was used, the metal was cooled by liquid oxygen, T detd. by thermocouples. The temp. of the plate could be varied by irradiation from a heating element in back of it; the surface was coated with various exptl. materials. The tracks of the mols. on the metal were rather diffuse round spots, never stretched in one direction, as at first expected. From the exptl. data with densities of incidence of $\nu = 0.52 \times 10^{17}$ ($T_{\text{furnace}} = 570^\circ$) and 1.13×10^{17} ($T_f = 589$) was found for Cd on picein, on mica and on copper at temps. of more than 193° , 186° and 176° , resp. (actually about 200° abs.), τ smaller than 10^{-6} sec. The fact that Δ and δ agree well if for calcn. of δ the plate temp. T_p is used (not the furnace temp. T_f) makes it obvious that there must be a measurable time of adherence larger than the proper vibration period of the mols.; therefore 10^{-12} sec. $< \tau < 10^{-6}$ sec. Also the accommodation coeff. (fraction of mols. assuming speed and energy of wall) is near unity. The results are not in agreement with those of Chariton and Semenov (*C. A.* 18, 3299), τ being considerably shorter. An objection to the method used is the imperfect gas removal (10^{-5} mm. Hg vacuum), which might have left gas adsorbed on the plate, although its surroundings were all at a 100° lower temp. The same objection, however, can be made to the work of C. and S.

Mixture of ethyl and amyl alcohols and water. B. LAMPE AND W. KILP. *Z. Spiritusind.* 51, 250 (1928).—The expansion in vol. and cooling resulting when amyl alc. is mixed with aq. EtOH are due to the affinity of the former for the EtOH . Density detns. of mixts. of Et and Am alcs. by an alcoholometer give the correct proportion of water because amyl alc. has the same effect on the d as EtOH .

A. SCHULTZ

The anisotropic liquids: facts and theories. C. W. OSEEN. *Univ. Upsala. Fortschr. Chem., Physik physik. Chem.* 20B, 87 pp. (1929).—This monograph gives a brief historical résumé, and a description of the phenomena of anisotropic liquids. Born's theory (cf. *Sitzungsber. k. preuss. Akad. Wissenschaften* 1916, p. 614) is based on the assumption that the mols. of a dielectric under the influence of the elec. field of the neighboring mols. are polarized so as to become elec. dipoles. Oseen's theory (for complete mathematical treatment cf. *K. Svenska Vetenskapsakademiens Handlingar* 61, 1921) considers the mols. as rigid bodies exerting forces on each other which are in part attractive, acting on the center of gravity, and partly torsional, tending to orient the mols. At sufficiently low temps. these forces cause the mols. to unite to form aggregates that explain adequately the properties of cryst. liquids (cf. Bose, *C. A.* 1, 2662).

First stages in the development of our views concerning the equilibrium system iron-carbon-oxygen. RUDOLPH SCHENCK. *Z. Elektrochem.* 34, 399-403(1928).—A reply to Falcke's criticisms (cf. preceding abstr.). J. H. REEDY

The resistance to bending of easily deformable materials, especially of vulcanized rubber. R. ARIANO. *India Rubber J.* 77, 136(1929).—A correction of equation 15 in the paper abstracted in C. A. 23, 747. C. C. DAVIS

Current conduction in extremely high resistance and solid insulators. FRITZ REGLER. *Physik. Z.* 29, 869-73(1928).—A theory of the mechanism of conduction in substances of high resistance and solid insulating materials is presented and compared with existing data. A great part of the resistance is assumed to exist in the transition regions between microcrystals. Change of resistance as a function of potential is due to changes in the size of unit cells. On the basis of these assumptions Ohm's law is no longer valid. FRANK URBAN

A method of simultaneous determination of plasticity and elasticity. E. C. BINGHAM AND J. W. ROBERTSON. Lafayette Coll., Easton, Pa. *Kolloid-Z.* 47, 1-5(1929)

Elastic deformation is independent of the time the force acts, while permanent deformation (plastic) is proportional to this time. The method measures the deformation during small unequal time intervals, and the results allow calcs. of the instantaneous deformation. Pressure is applied alternately to each end of a capillary contg. the material (43% ammonium oleate soln.); the period of application is governed by the speed of the compressing piston. An embedded particle is used to follow the deformation. The elastic and plastic components of the total deformation are calcd. G. CALINGAERT

The ditartrates of the alkali metals potassium, rubidium and cesium and of ammonium and thallium. MARY W. PORTER. *Z. Krist.* 68, 531-42(1928). (In English); cf. C. A. 22, 2089.—A crystallographic and optical study was made of this series of isomorphous orthorhombic compds. Densities, mol. vols., axial ratios, refractive indices, optical character, optical angles and dispersions are given. L. S. RAMSDELL

The solubility of Reinsch antimony films in water. S. G. CLARKE. *Analyst* 54, 99-101(1929).—The results of 6 tests of the soly. of Sb deposited on Cu show that it is not necessary to use "boiled out" water for washing the Reinsch coils but the washing should be done promptly and rapidly. W. T. H.

Surface oxidation of aluminum, tungsten and molybdenum. LEONARD C. BANISTER. Univ. of Liverpool. *J. Chem. Soc.* 1928, 3163-6.—Films of varying thickness were formed on the surfaces of Al, W and Mo strips by anodic oxidation. In all cases the results indicated that the films were oxides which cause interference of light in the visible region of the spectrum and so produce color. The color varies with the voltage and the no. of coulombs used in depositing the film. H. F. JOHNSTONE

Oxide films responsible for the tints on heated copper. ULICK R. EVANS. Univ. of Cambridge. *Nature* 123, 16(1929); cf. C. A. 22, 523.—Films of CuO formed on Cu are isolated by dissolving the Cu electrolytically in concd. K_2SO_4 soln. The oxide films peel off in curling flakes, which retain the grooves and ridges left by the abrasive treatment used to clean the Cu before oxidation. Thick films can also be removed mechanically. The tints of heated Cu are due to Cu_2O . In a too severe treatment, CuO is also formed, but it obscures the colors of the film. A flame of pure alcohol is suitable for obtaining a film of Cu_2O . ALBERT L. HENNE

Studies of salt coloration caused by pressure. K. PRZIBRAM. *Sitzb. Akad. Wiss. Wien, Abt. IIa*, 137, 409-421(1928); cf. C. A. 23, 331.—Previous observations of the influence of pressure on the discoloration of rock salt were confirmed. Crystals obtained from a melt do not show increased discoloration under moderate pressure. Under strong pressure the blue pressure coloration appears. The repression of the blue coloration by very high pressure is a function of the duration of the pressure. Ultramicroscopic observations show that the blue compressed salt is nearly optically void. It may be regarded as an intermediate stage between the yellow state and one colored blue by ultramicroscopy. The measurements of W. Ottmer on alkali halogens compds. (C. A. 22, 1277) confirm the author's "rule of the diagonal" as well as the relation between stability of coloration and electron linkage. FRANK URBAN

Absorption of carbonic acid by iron hydroxide. J. TILLMANS, P. HIRSCH AND K. SCHILLING. *Kolloid-Z.* 47, 98-101(1929); cf. C. A. 23, 1973.—Corrosion expts. led to the belief that dissolved H_2CO_3 was adsorbed by the $Fe(OH)_3$. Subsequent

work showed this to be true. The relation between free and bound H_2CO_3 was found and the probable mechanism described.

L. F. MAREK

Adsorption of arsenious anhydride by ferric hydroxide. A. BOUTARIC AND M. LLE. G. PERREAU. *J. pharm. chim.* **8**, 211-21(1928); cf. *C. A.* **22**, 2502.—A quant. study of the adsorption of As_2O_3 in soln. by $\text{Fe}(\text{OH})_3$ shows that this adsorption is practically instantaneous. Other conditions being equal, the quantity of As_2O_3 adsorbed increases (1) with the concn. of the As_2O_3 solns. in equal vols. taken; (2) with the vol. of the solns. of As_2O_3 having equal concn.; (3) with the quantity of $\text{Fe}(\text{OH})_3$ employed. Aging of the $\text{Fe}(\text{OH})_3$ and temp. have no appreciable influence. Expts. made with hydroxides of other metals (Al, Cr, Cd, Zn, Mn) show that $\text{Fe}(\text{OH})_3$ is far from being the best adsorbent for As_2O_3 ; the most active hydroxides are those of Zn and Mn.

S. WALDBOTT

Adsorption of gases by solid sodium chloride and in its water solution. FELIX DURAU. *Ann. Physik* **87**, 307-84(1928).—Adsorption by salt with and without heat treatment was measured. Adsorption isotherms at 480° were made with N_2 , H_2 , CO_2 , NO_2 , CH_4 , C_2H_6 , C_3H_8 , N_2O and SO_2 . Adsorption of N_2 by 2 samples of NaCl agreed. Equal results only were obtained for water vapor, since an aq. soln. forms about each single crystal of the salt, preventing accurate measurements. Adsorption of O_2 in the soln. takes place irreversibly because of the low vapor pressure of H_2O above such a soln. Of all gases studied besides H_2O vapor, SO_2 is the only one giving a complete monomol. layer on the surface, H_2 giving only about 1% of such a layer. This signifies pure adsorption. The gases appear to diffuse into the NaCl. Below 0.4 mm. pressure only SO_2 shows detectable adsorption. Adsorption increases with the b. p. of the material adsorbed. The dipole character of CO causes "super-adsorption." Adsorption is due to internal pressure and is influenced by any factor affecting the crystal lattice. This is evidenced by heat treatment. Pretreatment of NaCl with gases does not show noticeable effects on the adsorption isotherms.

RAYMOND H. LAMBERT

Method of determining the absolute magnitude of surfaces. O. HAHN AND F. BOBEK. *Ann.* **462**, 174-85(1928).—An extension of previous work (*C. A.* **19**, 1090). The methods already described have been applied to the detn. of the specific surfaces of two Th salts, with U X as the radioactive indicator. Th oxalate, pptd. from a hot soln. of Th nitrate by means of oxalic acid and then kept under the supernatant liquid for 2 $\frac{1}{2}$ hrs. at 100° , had a sp. surface (defined as g. of substance in surface per 1 g. of substance) of 0.0205%, while for Th oxalate pptd. in the cold the corresponding figure was 0.136%. Th hypophosphate, obtained by pptn. of a boiling soln. of the nitrate with hypophosphate, gave the figure 9.35%. The abs. surfaces of the 3 specimens are, therefore, 0.12, 0.78 and 52 sq. cm., resp., since the abs. surface = $p\sqrt{N/Ms^2}$, where M = mol. wt., N is Loschmidt's number, p is the specific surface, and s is the density of the substance under examn.

B. C. A.

An optical method of determination of particle size in suspensions. G. I. POKROVSKII. *Kolloid-Z.* **47**, 55-8(1929).—Description of an "opaloscope" or spectrophotometer for giving the av. size of colloidal particles from the Mie effect of the scattering of transmitted light. It is suggested for use in the examn. of flames and sprays.

G. CALINGAERT

Magnetic field and Brownian movement. A. TURPAIN AND BONY DE LAVERGNE. *Compt. rend.* **187**, 1280-2(1928).—Dispersions of Prussian blue, gamboge, $\text{Fe}(\text{OH})_3$, chrome yellow, Venetian red and vermilion are not affected by a magnetic field. Particles of Fe, Ni, Co or Cr, placed in the dispersions under the influence of the field, do not affect gamboge or vermilion, but coagulation takes place in the other dispersions by an agglomeration about the added particles of metal.

F. G. VANDEN BOSCHE

The discharge of colloid membranes in alkaloid solutions. N. K. HARKEVICH. *Kolloid-Z.* **47**, 101-4(1929).—An app. is described for the detn. of the charge on colloid membranes and the results of expts. using HCl solns. and solns. of various alkaloid salts with membranes of cellulose, collodion, pyroxylin and agar-agar are given.

L. F. MAREK

The reciprocal action of ions in diffusion. VL. S. BUTKEVICH AND V. V. BUTKEVICH. *Landwirtschaftliche Akad., Moscow. Biochem. Z.* **204**, 303-21(1929).—From the equation of Donnan's membrane equil. it follows that the diffusion velocity of a dissolved electrolyte depends not only on the nature and concn. of the electrolyte but on other electrolytes in the soln. as well. Furthermore, the velocity with increasing concn. of the electrolyte does not change in proportion to the total concn. but more nearly as the relative no. of undissocd. mols. These deductions were approx. verified by diffusion expts. using colloidion membranes. Expts. with variable concns. of KNO_3 showed that the equiv. diffusion is not const., but increases with rising concn., the increase being in direct proportion to the increase in relative no. of undissocd. mols. With limited concns.

the ratio $\Delta D/\Delta(1-a)$ is almost const. HNO_3 and its alkali salts within the concn. of 0.01 to 0.001 *N* give the same $\Delta D/\Delta(1-a)$ as KNO_3 . In the case of $\text{Ca}(\text{NO}_3)_2$ this ratio is $2/3$ to $1/2$ that for KNO_3 . The differences in diffusion rate of various electrolytes are also ascribed to difference in ion mobility, which is especially noted in case of acids with the very mobile H ion. From an NH_4NO_3 soln. the 2 components diffuse through a collodion membrane in equiv. amts. only at p_H 3; at lower p_H the velocity of diffusion of NH_4 ion increases while that of NO_3 ion decreases; at the neutral point the diffusion of NH_4 ion by far exceeds that of NO_3 ion. Diffusion of the Na salts of H_3PO_4 also depends upon the acidity, that for free H_3PO_4 being 3 times as great as for Na_3PO_4 . Any electrolyte when added to the soln. of another electrolyte must promote its diffusion.

S. MORGULIS

Theory of emulsions. WO. OSTWALD. *Kolloid-Z.* 47, 131-2(1929).—"Phase-volume-theories" of emulsions as reported in the literature refer explicitly to pure, 2-phase, unprotected, and therefore mono-disperse systems. The expansion of these considerations into a theory for the existence and stability of practical, polydisperse, protected emulsions is based on a misunderstanding which has been introduced into the literature by W. Clayton ("Theorie der Emulsionen," Berlin, 1924) and Bancroft (*C. A.* 6, 2026).

L. F. MAREK

Preparation of negatively charged sols by means of tartaric acid. II. The colloidal nature of Fehling solution. A. DUMANSKII AND A. A. CHALISEV. *Kolloid-Z.* 47, 121-31(1928); cf. *C. A.* 22, 4308.—Observations reported in the literature on the colloidal nature of Cu tartrate solns. generally postulate reactions in stoichiometric proportions. Expts. tend to show that this is not true. The $\text{Cu}(\text{OH})_2$ sol in the alk. Fehling soln. is a strong oxidizing and catalytic agent because of its highly dispersed nature. This colloidal nature accounts for: aging of the soln., oxidation of sugars, production of Cu_2O sols., evidence of catalytic reactions, some of the difficulties entering into quant. sugar detns., etc.

L. F. MAREK

The preparation of pure silicic acid solutions by means of electrodialysis. I. Electrodialysis. SHUMPEI OKA. Tokyo Imperial Univ. *Chem. News* 138, 67(1929)

Pure $\text{Na}_2\text{SiO}_3 \cdot 9\text{H}_2\text{O}$ crystals were used to prepare the solns. Electrodialysis was performed in a 2-compartment cell, with a parchment-paper diaphragm; purification was completed in a 3-compartment cell. The voltage (10 to 100 v.) was regulated to maintain a uniform c. d. (usually 4 amps.). When the total resistance became too large, a constant voltage (150 v.) was applied. The NaOH soln. in the cathodic compartment was siphoned every 30 minutes, titrated, and replaced by distd. H_2O . From the titration the apparent current efficiency was calcd. After about 1000 mins., pure H_2SiO_3 solns. were obtained, whose concns. ranged between 1.39 and 4.46%. The current efficiency decreased with the Na concn. in the silicate soln. The total loss of H_2SiO_3 ranged from 5 to 60% of the original silicate: it was due to coagulation on the anode surface, and also to slight diffusion through the diaphragm. The loss by coagulation was lessened by suitable control of c. d., agitation and large diln. of the soln. A. L. H.

Stabilization of colloids. V. KULIKOV. *Compt. rend. soc. biol.* 97, 1337-9 (1927).—A series of substances has been prepared which permit the formation of a colloidal soln. from two mutually insol. substances. B. C. A.

Colloidal solutions of carbon. H. LACHS AND KAROLINA GESTEL. *Z. physik. Chem.* 137, 193-200(1928).—Colloidal solns. of C were prepd. according to the method of Sabbatani (*C. A.* 8, 1690) except that dialysis was continued for 8-10 days. The solns. are reproducible, may be concd. by evapn. and will keep for weeks. With the paraboloid and immersion ultramicroscopes small, isolated sparkling particles and barely visible submicrons are seen in this sol. The sol does not change appreciably with time even at 90° and after coag. Since double refraction is absent the sol is considered entirely amorphous. Coagulation values for various electrolytes are given. Among those studied only Th salts coagulated the sol completely, leaving a colorless soln. The particles probably are not uniform in size. Ultrafiltration indicated that 75% of the C is dispersed in particles less than 140.8μ in diameter. Depolarization of the Tyndall light increases with concn. when the dispersion medium is very pure distd. water but it decreases when the medium is ordinary distd. water. RAYMOND H. LAMBERT

The stability of "submicrons." Decomposition and formation of crystals. Formation of emulsions. J. TRAUBE. Tech. Hochschule, Berlin. *Kolloid-Z.* 47, 45-7 (1929).—Ultramicroscopic observation of crystals of moderately sol. compds. of complicated structure indicates that the crystal walls resolve into large numbers of submicroscopic particles, which may have a "life" of one or more mins. In the formation of certain crystals the linking up of chains of such particles was observed. Observations on a $\text{CHCl}_3\text{-H}_2\text{O}$ emulsion are included. G. CALINGAERT

The state of solution of copper and iron in alkaline media in the presence of organic substances containing hydroxyl groups. WILHELM BACHMANN, PAUL GOLDSCHMIDT AND ERICH WEINGART. *Kolloid-Z.* 47, 49-55(1929).—Preliminary report of a comprehensive investigation, by dialysis, ultramicroscopy, ultrafiltration, and electrolysis, of the colloidal state of solns. of CuSO_4 and FeCl_3 with NaOH and addns. of glycol, glycerol, mannitol, dextrose, sucrose, inulin, dextrin and starch. The soln. character ranges from crystalloid (mol. complex) through colloid to suspension, depending on the proportions of alkali, org. addn. and added water.

G. CALINGAERT

Plasticity. H. A. J. PIETERS. *Chem. Weekblad* 26, 18-24(1929).—A review of plasticity, its detn. (direct and indirect) and of theories of the causes of plasticity with particular reference to clay. At least part of the confusion in matters of plasticity is due to the frequent use of clay as a test object where a homogeneous substance would allow more sharply defined conclusions. The plasticity of "clay" is that of a mixt. of a non-plastic substance and water; it depends on the clay species, the amt. of water, on electrolytes or org. substances present, etc. A very elaborate bibliography is given in footnotes.

B. J. C. VAN DER HOEVEN

The absorption of light in colloidal systems as a function of the thickness of strata. EDUARDO GALVEZ. *Kolloidchem. Beihefte* 28, 148-54(1929).—Consideration of the distribution of micelles in colloids and of the mechanism of light absorption, suggests a wave-like character for the curve for light absorption as a function of the strata. Application of this function to detg. the size of the micelle is considered. L. F. MAREK

Effect of temperature on the viscosity and ease of precipitation of sols of cellulose acetate and rubber. G. S. WHITBY AND W. GALLAY. McGill Univ., Montreal. *Trans. Roy. Soc. Can.* (preprint), [3], 23, 1(1929); cf. C. A. 22, 2079.—A rubber sol in C_6H_6 showed only a small temp. coeff. of change in relative viscosity. Small temp. coeffs. were also found for sols of cellulose acetate in phenylethyl alc., benzyl alc., acetone and cyclohexanone. The temp. coeff. of the relative viscosity was not found higher in the case of gelatinizing than in non-gelatinizing sols but if anything the reverse. The addn. of a non-solvent pptg. agent showed that a larger quantity of the pptg. agent was required as the temp. rose and the ease of pptn. was affected by temp. change much more than was the relative viscosity. The authors conclude that pptn. by a non-swelling agent is not a reliable method for comparing the degree of solvation at different temps.

J. W. SHIPLEY

Figures produced on drying colloidal solutions. PAUL BARY. *Rev. gén. colloïdes* 6, 209-21(1928).—On slow drying of colloidal Fe_2O_3 formed from FeCl_3 , parallel lines are shown, one region of which is much more basic than the other. Pectograms of colloidal Sb_2S_3 , Au, tannin, S, MoS_3 , Congo red, fuchsin, rubber in benzene, Cu oleate as well as Fe_2O_3 are shown and the method of prep. them is explained. Such pectograms give a new method for studying the structure of colloidal solns. of various kinds.

RAYMOND H. LAMBERT

The effect of electrolytes on organic iso-colloidal systems. LÁSZLÓ AUER. *Kolloid-Z.* 47, 38-43(1929).—When salts are dissolved in fatty oils (linseed, castor, sunflower) by heating, the oils increase in viscosity without the further prolonged heating which is usually necessary. There are distinct differences in viscosity produced by different anions and cations. The explanation is offered that oils are two-phase (iso-colloid) systems, the effect of the salt being to change the proportions of the phases.

G. CALINGAERT

The condition of the micelles in starch. M. SAMEC. *Kolloid-Z.* 47, 81-2(1929); cf. C. A. 22, 4309.—S. finds his views not in opposition to the complex theory of Malottiano.

G. CALINGAERT

The precipitation of gelatin by inorganic colloids. R. WINTGEN AND H. ENGELMANN. *Kolloid-Z.* 47, 104-21(1929).—Corresponding to the detn. of the equiv. wt. of colloidal Cr_2O_3 with stannic acid sols, the equiv. wt. of colloidal Al_2O_3 was detd. by coagulation and neutralization with colloidal stannic acid at the max. pptn. point. By pptn. with colloidal Cr_2O_3 and Fe_2O_3 sols the equiv. aggregate wt. of gelatin was detd. as 32,000, which agrees with the value obtained by osmotic pressure methods. By using colloidal Al_2O_3 the equiv. wt. was detd. as 19,700, presumably because all the charges on the oxide particle had not been neutralized. In acid soln. and with aging the gelatin showed an equiv. wt. very much greater passing through a max. when plotted against time of standing.

L. F. MAREK

Structure of clear sodium oleate gels and the particle count in these gels. R. ZSIGMONDY. *Kolloid-Z.* 47, 97-8(1929).—Contrary to the findings of McBain and Laing, Thiessen has shown a fine thread-like structure in clear, highly viscous sodium oleate

gels. For the same concn. the gel may be made either clear or contg. nuclei by changing the degree of undercooling.

L. F. MAREK

Transition temperatures of gel-forming systems. SAKAE TSUDA. *Kolloid-Z.* 47, 28-36(1929).—Gelatin sols at high temps. show neither viscosity of structure nor aging. Both properties appear simultaneously below a definite temp., which is 33-35° for solns. of 2 to 8% gelatin, and corresponds to the crit. temp. of gelatinization. Hg sulfosalicylate up to 100° shows no such transition temp. Salts or EtOH affects this temp. only slightly in the case of gelatin. Sols of agar behave differently from gelatin. The fact that the temp. of liquefaction is much higher than the temp. of solidification shows that, when it is heated, the previously cooled sol tends to retain its viscosity of structure.

G. CALINGAERT

Syneresis and hydration. The theory of syneresis. S. LIPATOV. *Kolloid-Z.* 47, 21-8(1929); cf. *C. A.* 22, 4314.—Further report of expts. with geranin, on velocity of syneresis and gelation in relation to concn. of geranin and degree of hydration. I. concludes that these are reversible processes governed by temp. and pressure, in contrast to irreversible, corresponding phenomena in SiO₂ gelation, for which some results are given.

G. CALINGAERT

Studies of surface tensions of solutions. I. The effect of salts upon the surface tension of aqueous urethan solutions: the measurements. SVEN PALITZSCH. *Tech. Hochschule, Copenhagen. Z. physik. Chem., Abt. A*, 138, 379-98(1928).—A critical review of the literature on surface tension and allied phenomena in salt-contg. solns. of "capillary-active" substances is given. P. has observed with considerable accuracy and care the influence of dissolved salts on the surface tension of aq. urethan solns. by use of the drop-weight method in air at 25°. He has measured the surface tension of pure urethan solns. of varying concn. and the effect of varied concns. of salts (NaCl, KCl, LiCl, CaCl₂·6H₂O, BaCl₂, HgCl₂, AlCl₃·6H₂O, KBr, KI, KNO₃, Na₂SO₄, (NH₄)₂SO₄, MgSO₄·5H₂O, MnSO₄, ZnSO₄·7H₂O, CuSO₄·5H₂O, K₂CrO₄, Na₂S₂O₃·5H₂O, KH₂PO₄, Na₂HPO₄·2H₂O, KClO₃, KBrO₃, K₃Fe(CN)₆ and K₄Fe(CN)₆·3H₂O) upon different aq. solns. of this material. The work is considered to be accurate to 0.2%. **II. The determination of surface tension by drop-weights.** *Ibid* 399-410.—P. gives a discussion of the use of the drop method, beginning with the simple equation of Tate. He explains Moran's manner of using the drop method and dwells on Harkins' treatment of the problem by the latter's introduction of the empirical correction factor, $f(r)/(V^{1/3})$; thus, $\gamma = (wG)/(2\pi f)(r/V^{1/3})$. P. agrees fully with Harkins and has developed a slightly modified treatment of the subject in direct accord with H.'s views. P. further shows that Iredale's (cf. *C. A.* 17, 2664) method and equation are mathematically derivable from H.'s formulas, the two considerations being of like principle. P. disagrees with Goard and Rudal (cf. *C. A.* 19, 3405) in their criticism of H.'s equation. **III. The effect of salts upon the surface tension of aqueous urethan solutions: discussion of results.** *Ibid* 411-31.—The results of P.'s measurements are treated in two ways, (1) variation of surface tension with urethan concn. at const. salt concn., and (2) change of surface tension with salt concn. at const. urethan concn. Consequently many plots are presented. For low concns. of urethan, the surface tension falls off less rapidly (even increasing in some cases) with rising salt concn. than for the higher concns. of urethan. Little theoretical treatment can be given.

WILLIAM E. VAUGHAN

The rotatory power of tartrates of organic bases. Study of strong electrolytes. E. DARMOIS. *Compt. rend.* 188, 388-90(1929).—Detn. of $[\alpha]_D$ as function of mol. concn. of tartrate ion (T²⁻) in solns. of tartrates of certain org. bases stronger than NH₃, gives decreasing $[\alpha]$ in following order: NH₄, NH₃Et, NH₂Et₂, NHEt₃, NEt₄, while benzyl amine gives considerable increase in $[\alpha]$ over NH₄. If the complete dissoen. of the Debye-Hückel theory is admitted, C₇H₁₀N⁺ and NEt₄⁺ act in contrary sense on T²⁻, but these two ions, judged by their mobilities, have nearly equal radii and their deformation of T²⁻ must be of same order. Only their hydration can be different. As C₇H₁₀N⁺ is probably not hydrated, NEt₄⁺ must be strongly hydrated. Methylammonium tartrates also give the same order for $[\alpha]$, which is in increasing order of hydration of ions as detd. independently. Diminution in $[\alpha]$ is attributable to dehydration; increase in $[\alpha]$, to deformation of T²⁻ provided no undissocd. mols. are present. A. P. SACHS

Liquid ammonia as a solvent and the ammonia system of compounds. III. The properties of solutions of metals in liquid ammonia. WARREN C. JOHNSON AND W. CONARD FERNELIUS. *J. Chem. Education* 6, 20-35(1929); cf. *C. A.* 22, 3082, 3365-6. A résumé of the work of Kraus and co-workers on liquid NH₃ soln. of the alkali metals. The nature of the reactions and of the elec. cond. of dil. solns. of these metals shows that they are ionized into ordinary alkali metal ions (positive ions) and solvated electrons (negative ions). Concd. solns. of the alkali metals exhibit metallic conductance. The

alkali metals do not form addn. compds. with NH_3 and the so-called "metal ammoniums" do not exist. When Na is dissolved in liquid NH_3 there is a remarkable decrease in the d. of the soln.

W. C. FERNELIUS

Solubility and solution velocity of solid compounds. E. N. GAPON. Chem. Lab. des Inst. für Volksbildung, Charkow. *Z. Elektrochem.* **34**, 803-5(1928).—The soln. of a solid compd. in a liquid solvent is regarded as a process analogous to vaporization. A relation between the velocity of soln., the heat of soln., and the soly. of the compd. is calcd.

ALBERT L. HENNE

Dielectric constants of some organic solvents. YOSHIKATSU MATSUIKE. Tohoku Imp. Univ. *Proc. Imp. Acad.* (Japan) **5**, 29-31(1929).—Dielec. consts. for C_6H_6 , PhMe, CS_2 , CCl_4 , Et_2O and CHCl_3 are reported for various temps. between the b. p. and f. p. For C_6H_6 and PhMe the values were calcd. from the equation $c = Dc_0 + k$, where c_0 is the elec. capacity of the cell without the liquid sample and c that of the same cell with the solvent. For the other liquids the equation $D = (D_0 - 1)[(c - c_0)/(c_s - c_0)] + 1$, where c_s is the elec. capacity of the cell filled with the reference liquid, C_6H_6 or PhMe, whose dielec. const. is D_0 . Full results will be published in *J. Chem. Soc. Japan*.

C. J. WEST

Selective solvent action. VII. Solubilities in mixed solvents. NORA GREGG-WILSON AND ROBERT WRIGHT. Glasgow Univ. *J. Chem. Soc.* **1928**, 3111-5; cf. *C. I.* **21**, 3296.—The soly. of PhNHAc in aq. acls., benzene-alc. solns., and in mixed acls. and the soly. of phenanthrene in aq. alc. solns. were studied. The results agree with the idea of selective influence of the different groups of the solvent mols. on the soly. of the solute.

H. F. JOHNSTONE

Improvements in the methods of refractivity measurements in solutions. W. GEFFCKEN AND H. KOHNER. Chem. Lab. Bayer. Akad. Wiss., Physikal. Chem. Abt. *Z. physik. Chem., Abt. B*, **1**, 456-65(1928).—In order to increase the convenience and accuracy of refraction measurements improvements in the detn. of refractive index and d. were devised. The Pulfrich refractometer was provided with a reading microscope and a more finely divided scale. A He tube was used instead of Na light as source of illumination. The cell was so altered as to permit of continuous change of samples and to prevent evapn. Provision was made for observing corrosive materials or those sensitive to air. The n of soln. and water were read directly after each other to eliminate error of varying zero-point corrections. The pycnometer was arranged to prevent evapn. during filling. The detns. of concn. by evapn. were improved to prevent spattering and loss of dry particles by air currents.

A. P. SACHS

The dependence of equivalent refractivity on the concentration of strong electrolytes in solution. H. KOHNER. Chem. Lab. Bayer. Akad. Wiss., Physikal. Chem. Abt. *Z. physik. Chem., Abt. B*, **1**, 427-55(1928).—Equiv. refractivity of solns. of LiCl , BaCl_2 , AlCl_3 , NaBr , Li_2SO_4 , Na_2SO_4 , $(\text{NH}_4)_2\text{SO}_4$, $\text{Al}_2(\text{SO}_4)_3$, NaClO_4 and $\text{Ba}(\text{ClO}_4)_2$ was detd. at 25° in concns. from 2 equiv. per kg. H_2O to satn. and was found to be dependent on concn., increasing or decreasing at varying rates with increasing concns. for the various salts. The equiv. refractivity at infinite diln. detd. by linear extrapolation gives values correct within the limit of error of direct detn. The equiv. dispersion is const. within limits of error.

A. P. SACHS

A new method of measuring osmotic pressure. ROBERT V. TOWNEND. *J. Chem. Education* **6**, 98-104(1929).—The method depends upon (a) the change in vapor pressure of a liquid with curvature of the surface; and (b) the fact that liquids will support a tension in virtue of the cohesive force between the mols. It is especially well adapted to the study of dil. solns.

W. C. EBAUGH

Correlation of freezing points and vapor pressures of aqueous solutions by Dühring's rule. CARL C. MONRAD. Univ. Michigan. *Ind. Eng. Chem.* **21**, 139-42(1929).—Dühring's rule states that if the temp. of one substance is plotted against the temp. at which another substance has the same vapor pressure, the curve produced is a straight line, i. e., $(T_1 - T_2)/(\theta_1 - \theta_2) = K$, and 2 points are sufficient to det. the line completely. Data for solns. of NaNO_3 , NaOH , KOH , CaCl_2 and NaCl show close agreement of observed and calcd. values of the slope of the Dühring line.

W. C. EBAUGH

Nernst's principle. A. CARRELLI. *Nuovo cimento* [N. S.] **5**, 341-6(1928).—Mathematical objection to Nernst's third law of thermodynamics.

L. T. F.

Hydrogen overvoltage with alloys. M. G. RAEDER AND D. EFJESTAD. Norges tekniske Høiskole, Trondhjem. *Z. physik. Chem., Abt. A*, **140**, 124-32(1928).—The H overvoltage was detd. by means of the c. d.-potential curves in the cases of the following alloys: Sn-Sb, Pb-Tl, Hg-Cd, Cu-Sn, Ag-Zn and Mg-Sn. Results previously published, (R. and Brun, *C. A.* **22**, 2133) are corrected. When mixed crystals are formed, the overvoltage curve may lie between those for each constituent separately (Hg-Cd), or it may

lie above that for either constituent (Sn-Pb, Cu-Sn, Ag-Zn). Eutectics seem to have little influence on the overvoltage: in the case of the Sn-Pb eutectic the value is intermediate between those for Pb and Sn. Compds. between the constituent do not affect the overvoltage measurably.

Reactions in liquid hydrogen sulfide. V. Reaction with furfural. R. E. MEINTS AND J. A. WILKINSON. Iowa State Coll. *J. Am. Chem. Soc.* 51, 803(1929); cf. C. A. 22, 3567.—Furfural and liquid H_2S were sealed in a glass tube and allowed to warm up to room temp. Reaction took place in which the O of the CHO group was replaced by S giving yellow crystals, m. 95–8°, corresponding to Baumann and Fromm's $C_5H_6O_2S_2$ (*Ber.* 24, 3591(1891)).

A. S. CARTER

The action of iodine on phosphoric acid and sodium phosphate. A. BERTHOUD AND W. E. BERGER. *J. chim. phys.* 25, 568–80(1928).—The rate of reaction between I and Na_3PO_4 is proportional to the concn. of I; it increases slightly more rapidly than the phosphite concn.; it is retarded by KI to a variable degree always less than unity; and it is retarded by H^+ to the order of about –1.3. The thermal coeff. varies from 4.81 to 4.01 between 0° and 30°. The rate of oxidation of H_3PO_4 by I is proportional to the I concn. and to non-dissocd. H_3PO_4 ; it is independent of the KI concn.; and it is slightly accelerated by H^+ . Its thermal coeff. is about 3.8 between 25° and 45°. Light does not sensibly affect either reaction.

R. H. LAMBERT

Experimental study of the transformation of chromates into dichromates. F. CARRIERE AND P. CASTEL. *Compt. rend.* 187, 1292–4(1928).—The equil. of the reaction $2CrO_4^{--} + 2H^+ \rightleftharpoons Cr_2O_7^{--} + H_2O$ was studied. $BaCrO_4$ was converted into the sol $BaCr_2O_7$ by addn. of HCl. Exptl. and calcd. values for the concn. of HCl with varying amts. of $BaCrO_4$ are given and found to agree for low concns. of $BaCr_2O_7$. The equil. const. is calcd. as follows: $K = [CrO_4]^2[H]^2/[Cr_2O_7] = [4.5 \times 10^{-8}]^2/[0.00165] = 3 \times 10^{-16}$.

E. G. VANDEN BOSCH

The influence of nonelectrolytes on the velocity of ionic reactions. A. VON KISS AND FR. L. HATZ. *Rec. trav. chim.* 48, 7–17(1929).—The influence of nonelectrolytes and of mixts. of electrolytes and nonelectrolytes on the rate of reaction of dil. I and thiosulfate solns. was detd. The rate of reaction increases with the concn. of sucrose or urea, but decreases with that of glycerol, MeOH, or EtOH. The rate of reaction in a 0.05 N aq. soln. of electrolyte contg. also 3 mols. per l. of EtOH was compared to the rate in the alc.-water soln. without the electrolyte; it was found that (1) the rate is always higher when electrolyte is present; (2) the order of decreasing effect, KNO_3 , K_2SO_4 , $Al_2(SO_4)_3$, NH_4NO_3 , $MgSO_4$, HCl and LiCl for the aq. soln. is also that for the alc. soln. with $Al_2(SO_4)_3$ and NH_4NO_3 reversed and (3) the relative increase in reaction rate is greater in the case of the alc. than aq. solns. in all cases except LiCl and $MgSO_4$. Expts. in which the concn. of NH_4NO_3 was varied first in an aq. soln. and then in a molar EtOH-water soln. and expts. in which LiCl was similarly varied showed that the accelerating activity in the aq. soln. is for LiCl greater and for NH_4NO_3 smaller than in the alc.-water soln. In some expts. 3 different concns. of reacting components were used. Such expts. lead to the conclusion that in the case of MeOH and EtOH, though the abs. rates in the alc.-water solns. are always less than for aq. solns., still the percentage increase in reaction rate with concn. of reactants is greater in the water-alc. than in the aq. solns. Furthermore, with increasing concns. of the nonelectrolyte, this percentage increase in reaction rate becomes more pronounced. For the most part, explanations for the above facts are not at present offered by the authors. In the case of the nonelectrolytes no simple relationship between the dielec. const. of the soln. medium and the reaction rate is found.

P. H. EMMETT

The velocity of combination of atomic hydrogen atoms. Z. BAY AND W. STEINER. Chem. Inst. of Berlin Univ. *Z. physik. Chem., Abt. B*, 2, 146–7(1929).—At H produced by discharge was drawn at a const. velocity through a tube 3 m. long and 2.5 cm. wide. At 3 places Wrede diffusion plugs for measuring the concn. of at. H were inserted. The distance between I and II was 51 cm., between II and III 95 cm. The mean of 6–8 measurements was taken for each datum. The catalytic influence of the walls was minimized by adding water vapor. By plotting time vs. concn. of at. H a straight line is obtained at 0.1 mm. pressure and a highly curved line at 0.2 mm. At a pressure of 0.2 mm. and at 35% H concn. the half period is 1 sec., a value agreeing with Bonhoeffer's (*Ergebn. d. exact Naturwiss.* 6, 215(1927)).

A. FLEISCHER

The laws of periodicity. P. PETRENKO-KRITCHENKO. Chem. Technikum Odessa. *Ukrainskii Khim. Zhurnal* 1, 304–6, also *J. prakt. Chem.* 120, 225–37(1929); cf. C. A. 19, 3053; 20, 369; 21, 1581; 22, 3574.—A review of the previous work on the velocity of reaction of aliphatic halides with KOH, Me₂NOH, Et₂NOH, Ba(OH)₂, TiOH, EtONa, Ag, NH₃, piperidine, H₂O, EtOH, AgNO₃, CH₃COOK and KCNS and of the periodicity

of optical properties in relation to unsatn. of hydrocarbons. As the number of halogen atoms increases, the reaction rate alternately falls and rises. In general, the mono- and tri-halogen compds. are more reactive than the di- or tetra-halogen compds. A. F.

Oxygen-compound formation with acetaldehyde at low temperature. D. L&B. COOPER. Dalhousi Univ., Halifax, N. S. *Proc. and Trans. Nova Scotian Inst. Sci.* 17, Pt. 2, 32-3(1928); cf. *C. A.* 22, 531.—A mixt. of powd. $(\text{AcO})_2\text{Mn}$ and a small amt. of AcH was placed in a bubbling tube. The tube was immersed in a $\text{CO}_2\text{-Et}_2\text{O}$ bath, and O_2 dried with P_2O_5 was circulated through the mixt. After about 12 hrs. approx. 20 cc. of O_2 was absorbed; the resulting soln. was of dark pink color. In an expt., in which 7 cc. O_2 were consumed, the final mixt. was titrated with NaOH. It was found that the entire amt. of O_2 absorbed had served for the formation of AcOH, though this formation may have taken place on warming the soln. to room temp. It is possible that the quantity of O_2 absorbed represents only the soly. of O_2 in AcH at low temp. No peroxide stable at room temp. was formed. G. SCHWOCH

The equilibrium constant of the esterification reaction in the gaseous phase. W. ŚWIĘTOSŁAWSKI AND S. POZNANSKI. *Roczniki Chem.* 8, 527-41(541 French)(1928).

The equil. const. K_g of the reaction between HOAc and EtOH in the gaseous phase was detd. The modified ebullioscope of Swietoslawski (*C. A.* 22, 514, 4012) was used and the compns. of the vapors formed in the equil. state were detd. The equil. const. was independent of temp. The mean value of K_g from 10 detns. was 59, the mean exptl. error being $\pm 10\%$. The value found by Edgar and Schuyler (*C. A.* 18, 777) is 7 times as large, but the exptl. error of the present detn. is $\frac{2}{3}$ as large as that made by E. and S. JAROSLAV KUČERA

Inhibition of chemical reactions. II. Mechanism of the inhibition of esterification by alkaline substances. KENNETH C. BAILEY. Trinity College, Dublin. *J. Chem. Soc.* 1928, 3256-8; cf. *C. A.* 22, 2917.—It is shown that the reaction between EtOH and AcOH occurs in two ways: (a) in the body of the liquid, and (b) on the surface of the containing vessel. The (b) type of reaction is inhibited by the following bases in the following order of increasing effectiveness: quinoline, pyridine, NaOH, NH_3 , piperidine. HCl catalyzes the reaction, while benzyl chloride, *m*-cresol, C_6H_6 , and CHCl_3 have no effect or a slightly accelerating one. DAVID DAVIDSON

Remarks on the thermodynamic theory of catalysis. R. DUBRISAY. *J. chim. phys.* 25, 581-6(1928). RAYMOND H. LAMBERT

Acid and salt effect in catalyzed reactions. XVIII. The dynamics of autocatalyzed ester hydrolysis. HARRY M. DAWSON AND WILLIAM LOWSON. *J. Chem. Soc.* 1928, 3218-27; cf. *C. A.* 23, 1337.—The rate of the autocatalytic hydrolysis of ethyl acetate was studied, over a variation in concn. of the acid catalyst of 0.0002 to 0.2 mols. per l. A fused-silica reaction vessel was used to avoid the retarding effect of traces of dissolved alkali noticeable almost invariably when glass vessels were used. "The reaction may be divided into 2 stages in the first of which the velocity is detd. by the joint catalytic action of the H and OH ions, and in the second by the catalytic activity of the H ion." Equations are derived from which the time required to reach any given point may be readily calcd. The velocities of the uncatalyzed reaction and of that due to the catalytic effect of water mols. are considered too small to influence the course of the reaction measurably. The kinetics of the reaction are worked out for that region of concns. in which the rate of the back reaction may be neglected. P. H. EMMETT

Surface chemistry of contact catalysis. GEORG M. SCHWAB AND ERICH PIETSCH. *Z. physik. Chem., Abt. B*, 1, 385-408(1928).—On the assumption that catalytic reactions between gases take place as a result of collisions in the 2-dimensional monomol. gas on the catalyst surface or in the 1-dimensional line of mols. at the interface of the surfaces of 2 solid phases, a new set of kinetic equations is developed differing from the usual treatment of the subject. *Adsorption isotherm* equations analogous to Langmuir's adsorption isotherm equation are derived and defined as expressing the quantity of gas going from the 2-dimensional adsorbed gas layer into the interface boundary line sepg. 2 surface phases. Both ideal and "unideal" 3-dimensional, 2-dimensional and 1-dimensional gases are considered. Langmuir's adsorption isotherm is derived thermodynamically. The kinetic equations obtained are identical with those developed from the theories of Langmuir, Hinshelwood and others, in the case of single reacting gases. In the case of 2 reacting gases, there are differences but the exptl. data available do not suffice for choosing between the 2 methods of development. Well-known interfacial surface phenomena and Taylor's "active spot" theory are explained satisfactorily by the point of view herein presented. P. H. EMMETT

The effect of heavy metals on the autoxidation of alkali sulfides and of hydrogen sulfide. HANS A. KRAUS. Kaiser Wilhelm-Inst., Berlin-Dahlem. *Biochem. Z.* 204,

343-6(1929).—The velocity of absorption of O_2 by various sulfides (Na_2S , $NaHS$, $(NH_4)_2S$, and H_2S) was measured in the presence or absence of heavy metals (Mn , Ni , Co , Fe , Cu). In the presence of the metal catalysts the O_2 consumption is practically doubled.

S. MORGULIS

Making preparations through the use of catalysts in organic chemistry instruction. STEFAN GOLDSCHMIDT AND LUDWIG ORTHNER. Tech. Hochschule, Karlsruhe, Germany. *Z. angew. Chem.* 42, 40-2(1929).—An app. consisting of an elec. tube furnace contg. a tube serving as reaction chamber, a thermocouple, and control devices for input and output, is described. Examples of processes used include (1) Me_2CO from glacial $AcOH$; (2) $AcOEt$; (3) $C_6H_5NH_2$; (4) AcH ; (5) ketene from $(Me)_2CO$; and (6) C_2H_4 .

W. C. EBAUGH

Study of the action of iron catalysts on mixtures of carbon monoxide and hydrogen. ETIENNE AUDIBERT AND ANDRÉ RAINEAU. Société nationale de recherches sur le traitement des combustibles. *Rev. ind. min.* 1928, No. 182, 286-314.— Fe , Ni and Co exert a catalytic action on mixts. of CO and H_2 and this study was to det. if these metals when in contact with gaseous mixts. would give liquid org. products. A study was made of different mixts. with a hydrated Fe_2O_3 base consisting of 98 parts anhyd. Fe_2O_3 and 2 parts of the following: Na_2CO_3 , Li_2CO_3 , $CaCO_3$, $SrCO_3$, $BaCO_3$, $MgCO_3$, $ZnCO_3$, $MnCO_3$, $CuCO_3$, Ag_2CO_3 , Al_2O_3 , Mo_2O_3 , TiO_2 or SiO_2 ; of these 15 mixts. those contg. an alkali carbonate (Na_2CO_3 or Li_2CO_3) formed org. liquids with gas of compn. $CO + 5H_2$ under 150 atm. pressure and a flow of 3000 cu. m. All the others gave CH_4 , CO_2 , slightly acid H_2O and finally C . There were then studied 5 mixts. with a ferric hydrate base, consisting of 98 parts Fe_2O_3 and 2 parts of the following: K_2SO_4 , K_3PO_4 , KNO_3 and K_2S . No oil was formed by the K_2S catalyzer but the other catalysts produced 11 cc. per cu. m. of gas from the sulfate; 9 cc. per cu. m. of gas from the phosphate, 13 cc. per cu. m. of gas from the borate; and 19 cc. per cu. m. of gas from the nitrate, with gas ($CO + 5H_2$) under 150 atm. pressure and a flow of 3000 cu. m. Mixts. were then prepd. by pptg. mixt. of Cu nitrate and Fe nitrate with an alk., adding to the ppt. K_2CO_3 in proportion to the Fe content and after drying, submitting the compd. obtained to the action of H_2 under atm. pressure at 200° for 4 hrs. and at 300° for 14 hrs., in such a manner as to reduce only the CuO but not the Fe_2O_3 . It was shown that the presence of Cu increased the catalytic action of the Fe_2O_3 - K_2CO_3 couple; the compn. of the catalyzer after reduction at 300° was Fe_2O_3 49.5, Cu 49.5, K_2CO_3 1.0%. With this compd. there were extd. from the $CO + 5H_2$ mixt. a mixt. of water and different org. liquid products in the following proportions: (1) Light carburetants (55-180° fractions of oil) 28.8%, light oil from activated charcoal 5.0%, alc. in soln. 29.0%, or a total of 62.8%; and (2) clear oil, 180-250°, 14.0%; (3) heavy oil, 250-330°, 10.0%; (4) paraffin 7.1%; (5) tar, 2.7%; (6) fatty acids distg. at 110° to 140° (weak acetic, propionic and butyric, 3.1%. With the Cu - Fe_2O_3 - K_2CO_3 catalyzer, it is not possible to lower the temp. and still be assured of regularity of the phenomena of transformation of the mixt. of CO and H_2 .

Autoxidation and antioxygenic action. Catalytic properties of silicon, boron and their derivatives. CHARLES MOUREU, CHARLES DUFRAISSE AND PIERRE LAPLAGNE. *Compt. rend.* 187, 1266-9(1928); cf. *C. A.* 22, 1265.—The catalytic effects of Si , B and their derivs. on the oxidation of various compds. studied are listed below (ox. = oxygenic)

	C_6H_5CHO	Na_2SO_3 (alk.)	Na_2SO_3 (acid)	C_3H_7CHO	Styrolene	Turpentine	Acrolein	Furfural
Si	retards	retards	hastens	hastens	pro ox.
SiO_2	no action	anti-ox.	no action	anti-ox.	no action	anti ox.
$SiCl_4$	anti-ox.	anti-ox.	hastens	anti-ox.	pro-ox.	pro-ox.	anti ox.
$SiBr_4$	anti-ox.	anti-ox.	hastens	pro-ox.	pro-ox.	anti ox.
SiI_4	anti-ox.	anti-ox.	retards	pro-ox.	pro-ox.	retards then pro ox.	pro ox. anti ox.
$SiHCl_3$	anti-ox.	anti-ox.	anti-ox.	hastens	hastens	anti ox.
$SiCl_3CH_3-C_6H_5$	anti-ox.	anti-ox.	hastens	hastens
$Si(C_2H_5)_4$	hastens	retards	retards	hastens
$Si(OC_2H_5)_4$	retards	retards	retards	retards	retards
$Si(C_6H_5)_4$	hastens	hastens	hastens	hastens	hastens	pro ox. then anti ox.
B	retards	hastens	hastens	hastens
BCl_3	anti-ox.	hastens
BBr_3	anti-ox.	retards	anti-ox.	hastens	hastens	prevents then hastens

As catalysts H_3BO_3 , $Na_2B_4O_7$ and $(C_2H_5)_2B_2O_7$ were weak or ineffective.

E. G. VANDEN BOSCHE

Experiments with carefully dried substances. D. McINTOSH. Dalhousie Univ., Halifax, N. S. *Proc. and Trans. Nova Scotian Inst. Sci.* 17, Pt. 2, 34-40(1928).—A mixt. of 2 mols. CO and 1 mol. O₂ is not ignited by the elec. spark, if the gases have been dried with freshly distd. P₂O₅. If the drying is performed by cooling the lower part of a Dewar flask in a CO₂-Et₂O-bath, the mixt. usually does not explode. On warming the Dewar flask explosion occurs when the bath temp. reaches -50° to -60°. A mixt. of CO and NO dried by cooling to -80° always explodes. Finely ground Na sulfate, in which all crystals have been destroyed by thorough air-drying, is not rendered inactive for bringing about crystn. of a supersatd. soln. of Na sulfate; on the contrary, crystn. takes place promptly. The same result is obtained when a side tube, which can be filled with P₂O₅ or immersed in liquid air, is attached to the app. used. Immediate crystn. is also observed when instead of the Na sulfate powder, glass hairs that have been rubbed gently over a Na sulfate crystal are introduced into the app. The pptg. action is due to the decahydrate, since no pptn. occurs when the tubes of the app. are heated to 45° before cooling them and introducing the Na sulfate. Expts were conducted to investigate whether carefully dried Hg and Cl will react with each other. In the app. used the vapors given off by Cl at -180° do not react with Hg; when, however, the tension of the Cl vapors is allowed to rise by warming the bath, a reaction can be noted. Vapors of HBr and NH₃ liberated from the resp. liquids at -80° react with each other as seen by the appearance of NH₄Br clouds on opening the app. after 24 hrs. The b. p. of Et₂O is not affected by distg. it several times at -80°. Attempts made to dry Et₂O with P₂O₅ under special precautions were unsuccessful. G. SCHWOCH

The kinetics of the reaction between metallic calcium and nitrogen. A. VON ANTROPOFF AND E. GERMANN. *Z. physik Chem* 137, 209-37(1928).—The object of this expt. was to det. the activity and passivity of metallic Ca when acted upon by N₂. The app. is described. Technical Ca obtained from magnesia works was analyzed for impurities. Three forms were isolated for study as follows: 1 always active, 2 sometimes active and again passive and 3 always passive. 1 and 3 showed traces of Na, Mg, Al, Fe, SiO₂, Ca₃N₂ and CaCl₂. At 350° 1 was converted quickly and completely into Ca₃N₂; 2 was sometimes converted completely and sometimes barely attacked; 3 was inert even after 7 days in the gas at 400°. Ca₃N₂ does not catalyze the reaction. At 400-440°, the reaction between pure Ca and pure N₂ takes place in three stages: a, a fast reaction involving only atoms of Ca on the surfaces of crystals, b, a very slow reaction involving atoms beneath the thin skin of Ca₃N₂ and c, a second fast reaction after the skin of nitride has reached a definite thickness. O₂ prevents N₂ from reacting with a fresh surface of Ca but a skin of Ca₃N₂ once having formed the metal is protected against O₂ and the N₂ action proceeds. Li, Na, K and probably also Rb and Cs influence the reaction greatly not as catalyzers but rather as "reaction excitors." They probably change the state of the nitride. RAYMOND H. LAMBERT

A contribution to molecular-statistical thermodynamics. ERIK SVENSON. *Ann. Physik* 87, 424-60(1928).—A statistical treatment of thermodynamics is given in which the Boltzmann principle for entropy is involved. RAYMOND H. LAMBERT

(London)* A122, 688-718(1929).—The new wave-length data of Gale, Monk and Lee (C. A. 22, 1737) have been used to confirm the extensive series of Q branches previously reported (C. A. 21, 705) and to work out the associated P and R branches. This enables the rotational structure of these bands to be detd. Since they are analogous to the principal series of orthohelium they are designated as the $2^3\text{S} - m^1\text{P}$ bands. Comprehensive tables present the details. In addition to these bands another system designated as the $2^3\text{S} - 3^3\text{S}$ bands has been worked out. They lie in the red and infra-red and are characterized by the presence of P and R branches and the absence of Q branches. A table is given contg. the mol. consta. (including moments of inertia and nuclear sepns.) for the various excited states. C. C. KISS

A band absorption spectrum of iodine in an extreme ultra-violet region. MASA-MICHI KIMURA AND MICHIO MIYANISHI. *Sci. Papers Inst. Phys. and Chem. Research (Japan)* 10, 32-42(1929). (In English).—The continuous light of a H discharge tube was passed through a quartz tube containing I vapor at various temps. and was photographed with a quartz spectrograph. The absorption spectrum of I thus obtained was found to consist of a no. of bands having their edges on the violet side and nearly equally spaced. At a temp. of about 35° the bands extend from 2064 to 1950 Å. U., but with increasing temp. these bands fade away and are replaced with a new set, which at 120° extend from 2145 to 2066 Å. U. The wave lengths of the bands have been measured and are tabulated. These bands have been arranged into several series sepd. by about 210 cm.⁻¹ which are represented by the formula $\nu = 52,800 + 78n' - n'^2 - 210n$ in which n represents the vibrational levels of the normal state of the mol. and n' those of the excited states. C. C. KRESS

The symmetry of protonic wave functions. BENEDICT CASSEN. Calif. Inst. Technology, Pasadena. *Proc. Natl. Acad. Sci.* 15, 29-31(1929).—Mathematical treatment of the symmetry properties of a H₂ mol. indicates that the total protonic wave function is symmetric. This result is independent of whether the protons themselves have spins. If wave functions are symmetric for protons, then similar particles, atoms or mols., contg. an even no. of electrons, will satisfy the Einstein-Bose statistics, while those contg. an odd no. of electrons will satisfy the Fermi-Dirac statistics. R. J. H.

The dispersion electrons of lithium. J. HARGREAVES. Univ. Cambridge. *Proc. Cambridge Phil. Soc.* 25, No. 1, 75-96(1929).—The method initiated by Hartree (*C. A.* 22, 1269) for the numerical soln. of the Schrödinger wave equation for an atom with a non-Coulomb field of force is used to est. the no. of dispersion electrons (f) corresponding to the lines of the principal series of the optical spectrum of Li, and also to the continuous spectrum at the head of the series. For the continuous spectrum $\Sigma f = 1$ is found to a good approximation in agreement with the assumption of Sugiura (*C. A.* 21, 3817). MARIE FARNSWORTH

Luminescence caused by α -particles and its relation to the particle energy. BERTA KARLIK AND ELIZABETH KARA-MICHAILOVA. *Sitzb. Akad. Wiss. Wien, Abt. IIa*, 137, No. 7, 363-80.—The intensity of scintillation is closely connected with the energy and ionizing power of α -particles. The luminescence of ZnS caused by α -radiation was measured by means of the charge of a Wulf electrometer due to a Rb photoelec. cell. The ZnS was a de Haën prepn. of 30 to 40 μ particle size. Screen fatigue could not be observed even after 15 mins. irradiation. The arrangement made it possible to compare the luminescence for samples of 20-3000 e. s. u. The photoelec. currents measured on the same day were found to be a linear function of the no. of colliding particles and the luminescence. An app. for the detn. of the luminescence as a function of the velocity of α particles is described. For certain "good" scintillating substances the light intensity is proportional to the energy given off by the α -particles. For poorly scintillating ZnS samples the luminescence is proportional to the remaining range, up to a satn. value coinciding with complete penetration of the particle. These results are in satisfactory agreement with older measurements carried out on single scintillations. FRANK URBAN

Photographic intensity measurements of polonium preparations. MARIETTA BLAU. Radium Inst., Wien. *Sitzb. Akad. Wiss. Wien, Abt. IIa*, 137, 259-68(1928).—It is shown that the α -intensity of Po preps. can be measured by a simple photographic method. A comparison of the photographic method with the values obtained from ionization methods for preps. of equal size gives a good confirmation of the Bunsen-Foscoe law. Equal blackening is obtained with continuous or with intermittent raying with α -particles. MARIE FARNSWORTH

The passage of β -rays through matter. C. E. EDDY. Univ. Cambridge. *Proc. Cambridge Phil. Soc.* 25, No. 1, 50-61(1929).—The form of the absorption curves of homogeneous β -rays in Al is investigated by means of a Geiger counter. It is found that the main portion of the curve is linear, with pronounced initial and final flattenings. Similar initial flattenings are found for Cu and Ag, but not for Au. The range of β -rays emergent at different angles is detd., and it appears that the loss of range is due to the increased path consequent upon scattering. Some evidence is obtained of the angular distribution of plurally scattered particles, and of the existence of a most probable angle of scattering, similar to that found for α -rays by Geiger. M. F.

Potassium and rubidium rays. MARIE KUBAN. Radium Inst. Wien. *Sitzb. Akad. Wiss. Wien, Abt. IIa*, 137, 241-57(1928).—From ionization and photographic methods and making corrections for scattering from thick layers, the absorption coeff. for the β -rays of K in Al is 28 cm.⁻¹ and for Rb, 173 cm.⁻¹. Assuming that an isotope

of K of at. wt. 41 is responsible for the activity a half-life $T = 1.31 \times 10^{10}$ yrs. can be calcd.

MARIE FARNSWORTH

The quantum mechanics of an electron or other particle. F. H. KENNARD. Cornell Univ. *J. Franklin Inst.* 207, 47-78(1929).—K. points out that the new quantum mechanics cannot yet be considered as a coherent and completed theory. The parts which rest upon the firmest exptl. basis are probably the ones that deal with at. and mol. energies and the treatment of electron and photon beams by means of a probability amplitude propagated according to a wave equation. According to theory, protons also should exhibit wave properties but as yet exptl. proof of this is lacking. The new Fermi-Dirac statistics find a basis in quantum mechanics but the only application of it which has met with convincing success is again one to electrons, namely, the new form given to the theory of metallic conduction by Sommerfeld. MARIE FARNSWORTH

Ionizing potentials and far ultra-violet lines of light atoms. LOUIS A. TURNER. Princeton Univ. *Phys. Rev.* 32, 727-36(1928).—By an interpolation the ionizing potentials of F and F^+ are found to be 17.4 and 34.5 v. These new values improve the regularity of the relationships of the values of $(\nu/R)^{1/2}$ corresponding to the ionizing potentials of the atoms of the first short period where ν is the frequency and R is Rydberg's const. The energy necessary for the removal of a 2 s electron from each of many of the atoms and ions of these elements (L_{II} levels for an atom) is calcd. by the use of $s^2p^{n-1} - sp^n$ lines. The effect of the removal of a 2 s electron upon the subsequent removal of a 2 p electron is found for B, F and Ne to be an increase of $(\nu/R)^{1/2}$ by about 0.45. This is used to obtain a prediction of the wave length of missing $s^2p^{n-1} - sp^n$ lines of C, N, N^+ and O. New identifications of the far ultra-violet lines of Mg are proposed and the third ionizing potential is found to be 80.4 ± 1 v. A pair of lines of F are tentatively identified as the $2s^22p^{5/2}P - 2s2p^6^2S$ lines. BERNARD LEWIS

Ionization by collisions of the second kind in mixtures of oxygen with the rare gases. H. D. SMYTH AND E. C. G. STUECKELBERG. Princeton Univ. *Phys. Rev.* 32, 779-83(1928).—Harnwell's expts (*C. A.* 21, 2098, 2427) on ionization by collisions of the second kind have been continued. Mixts. of O with A, Ne, He and incidental effects of H_2O vapor have been studied. Evidence of the following collisions of the 2nd kind was obtained. $A^+ + O_2 \rightarrow O_2^+ + A$; $A^+ + H_2O \rightarrow H_2O^+ + A$ (very strong); $H_2O^+ + O_2 \rightarrow O_2^+ + H_2O$; $Ne^+ + O_2 \rightarrow O^+ + O + Ne$; $He^+ + O_2 \rightarrow O^+ + O + He$; The expts. confirm the conclusions of Hogness and Lunn (*C. A.* 20, 2946) as to the process of ionization in O_2 but leave the exact value of the first ionizing potential uncertain. BERNARD LEWIS

The effect of water vapor on the mobility of gaseous ions in air. HENRY A. ERIKSON. Univ. of Minnesota. *Phys. Rev.* 32, 791-4(1928).—Addnl. results are given in this communication which indicate that a H_2O mol. gives up an electron to the final pos. air ion and thus forms a H_2O^+ ion of greater mobility. Results are also presented showing that the reciprocal of the mobility bears a linear relationship to the humidity. BERNARD LEWIS

The ionization processes of iodine interpreted by the mass spectrograph. T. R. HOGNESS AND R. W. HARKNESS. Univ. of Cal., Berkeley. *Phys. Rev.* 32, 784-90 (1928).—With an app. in which positive ions, formed by electrons of definite energy are accelerated and then deflected magnetically around a semicircle into a Faraday cylinder, the relative nos. of the ions I^+ , I_2^+ and I_3^+ were measured as a function of pressure from 2×10^{-5} to 4×10^{-3} mm.¹ In the primary process of electron collision I^+ and I_2^+ were both formed. I_2^+ was also formed in secondary collision from I^+ by the process $I^+ + I_2 = I_2^+ + I$ and I_3^+ was formed from I^+ by the process $I_2^+ + I_2 = I_3^+ + I$. Evidence and arguments against other possibilities are given. The disappearing potentials of I^+ and I_2^+ were found to be identical, 9.3 v. Three neg. ions, I^- , I_2^- and I_3^- , were found to exist in quantities comparable with those of pos. ions. Pressure-intensity relationships of these ions were also detd. I^- is formed both near the filament and in the ionization chamber according to the equation $I_2 + E^- = I^- + I$. I_2^- and I_3^- are not formed by collisions with free electrons but as a result of secondary collisions of I^- and I_2^- , resp., with I_2 mols.; $I^- + I_2 = I_2^- + I$; $I_2^- + I_2 = I_3^- + I$. B. L.

Efficiency of ionization in hydrogen by positive-ion impact at 7000 volts. RONALD W. BURNBY. Princeton Univ. *Phys. Rev.* 32, 795-8(1928).— H_2 at low pressure was bombarded with K pos. ions of 7000 v. energy in a tube attached to a pos.-ray box. Any H ions and scattered K ions passing into the latter are distinguished by mass analysis. The applicability of this method for measuring the efficiency of ionization is dis-

cussed. If the H_2 mols. receive kinetic energy from the 7000 v. which ionize them, they will be scattered in all directions, and only those which happen to be projected toward the slit will enter the pos.-ray box. If ionization is unaccompanied by transfer of kinetic energy, the method is competent to compare the ionization efficiency with that of electron impact. With small pos.-ion emissions no ionization was detected, with larger emissions a violent discharge took place through the tube. Conclusion: Either the ionizing efficiency is less than $1/150$ of that of 50-v. electrons, or less ionization is accompanied by transfer of kinetic energy.

BERNARD LEWIS

Polarization of canal rays in a weak electric field. II. The extinction coefficient of $H\beta$ in various field arrangements. E. RUPP. *Ann. Physik* 87, 285-97(1928); cf. *C. A.* 22, 727.—The arrangement of the app. in which the elec. field may be changed is given in which a Babinet-Soleil compensator is used and the ratio of beam intensity parallel to the ray to that perpendicular to the ray is measured. The potential was varied from 2600 to 10,000 v. while the field strength of the condenser was varied from 75 to 600 v. Several canal arrangements also were studied. Both cross-sectional and longitudinal as well as non-homogeneous fields were examd. Graphs and tables are given of the results.

RAYMOND H. LAMBERT

Character of the photoelectric cells of alkali metals. SOICHIRO ASAO. Tokyo Elec. Co. *Mazda* 3, 155-65(1928).—A photoelec. cell was made in which the anode was a glass bulb on the inner wall of which was deposited metallic Na, K or their hydrides, a metallic ring being used as cathode. Although the results obtained with cells of various sizes and various methods of prepn. were not reproducible, the anode current-anode voltage curve, anode foot-candle power-anode current curves were detd. with a few representative cells made. Na was found to be superior as a pure metal, while the hydride increased the sensitivity several times. When instead of making the bulb vacuum, A was filled in it, the anode current increased considerably on account of discharge as well as by virtue of the photoelec. current. Similar expts. were made with a cell made by silvering the wall of the bulb and placing a Ni plate at its center to serve as a cathode.

K. SOMEYA

Hall effect and magnetic induction in a bar of electrolytic iron. EMERSON M. PUGH. Univ. of Pittsburgh. *Phys. Rev.* 32, 824-8(1928).—The Hall effect was measured in a bar of electrolytic Fe in contrast to the usual method of measuring it in thin sheets of the material. Direct measurements were taken at the same time of the magnetic induction B and of the Hall e. m. f., E . The E -vs.- B curve is a straight line up to $B = 12,000$ gauss at which point its slope starts to decrease. The curve of permeability vs. B has its max. at this same value of B . Measurements taken at points on a "hysteresis loop" indicate that E is also proportional to B when the magnetizing force has been removed and only the residual B remains. The Hall coeff. for this bar is found to be only 20% lower than that found by A. W. Smith (*Phys. Rev.* 30, 1(1910)) for electrolytic Fe, if in its calcn. the value of B is substituted for H in the usual formula.

BERNARD LEWIS

The dielectric cohesion of rare gases. MAURICE CURIE AND ADOLPHE LÉPAPE. *Compt. rend.* 187, 1283-5(1928).—A continuation of the work of Bouty (cf. *C. A.* 7, 1658). A method is given for measuring the dielec. cohesion, γ , of gases. The following values are given for γ at 17° : He = 19.8; Ne = 6.3; A = 18; Kr = 41.4; Xe = 131.2, air = 398. Values for the resonance and ionization potentials of the gases are also given.

E. G. VAN DEN BOSCHE

Total reflection of x-rays from nickel films of various thicknesses. HIRAM W. EDWARDS. Univ. of Cal. at Los Angeles. *Phys. Rev.* 32, 712-4(1928).—The total reflection of x-rays ($\lambda = 0.707$ A. U.) is obtained from mirrors of sputtered Ni films having thicknesses from 0 to 3.3×10^{-8} cm. The measured crit. angles varied from a min. value of 0.0016 radians, that of blank glass, to a max. value of 0.00339 radians which was obtained from the thickest Ni film. A satisfactory agreement between the max. exptl. value of the crit. angle and that calcd. by the Lorentz dispersion formula in which the d. of Ni was placed at 8.75 g./cc., is used as evidence for concluding that the d. of Ni is entirely normal and also that the thickness of sputtered metal films which are to be used in x-ray reflection phenomena must be sufficiently large or misleading results may be obtained. The crit. angle from a thick Ag sputtered mirror was found to be identical with that obtained from a chemically prepd. Ag mirror which indicates that the d. of Ag is independent of the method of deposition.

BERNARD LEWIS

X-ray analysis of solid carbon disulfide. J. DE SMEDT. *Physica* 9, 5-8(1929).—Using a previously described app. for detn. of x-ray diagrams of solids at low temp. (*C. A.* 19, 1816) two sharp Debye-Scherrer crystallograms were obtained of solid CS_2 .

at -185° with $\text{CuK}\alpha$ light. The distance of film to crystal tube was 27.3 mm., the radius of the crystal cylinder 1 mm. For a tetragonal structure $a = b = 8.12$ A. U., $c = 3.77$ A. U. within the limits of error for intensities; with 3 mols. per unit cell, d . (calcd.) = 1.51 as compared with d . (measured) of 1.55 at the m. p. The C atoms are placed at 0, 0, 0; $\frac{1}{2}a$, 0, $\frac{1}{2}c$; 0, $\frac{1}{2}a$, $\frac{1}{2}c$, the S atoms are at p , p , 0; $-p$, 0; $\frac{1}{2}a + p$, $-p$, $\frac{1}{2}c$; $\frac{1}{2}a - p$, p , $\frac{1}{2}c$; p , $\frac{1}{2}a - p$, $\frac{1}{2}c$; $-p$, $\frac{1}{2}a + p$, $\frac{1}{2}c$. The parameter, p , distance of C and S was found to be $0.157a$; this means close packing.

B. J. C. VAN DER HOEVEN

The metals iron, cobalt, nickel and copper used as diffraction gratings of corresponding x-radiations. S. PASTORELLO. *Nuovo cimento* [N. S.] 5, 284-9(1928).—P. finds that by photographing, one of the elements Fe, Co, Ni or Cu by using as a anticathode the immediately preceding element in the order of at. no. always showed clearly the characteristic lines of its own cryst. structure without sensible fogging through diffuse radiation. By using the element immediately succeeding that photographed as anticathode good results were also obtained. Cu used as anticathode for Fe gives rise to diffuse radiation and fogging so as to obscure the characteristic lines of the element photographed.

L. T. FAIRHALL

A determination of the wave length of the $\text{K}\alpha$ line of carbon. B. B. WEATHERBY. Univ. of Pa. *Phys. Rev.* 32, 707-11(1928).—A simplified type of vacuum spectrometer utilizing a plane glass grating with 250 lines per mm. was used to measure the wave length of the $\text{K}\alpha$ line of C. A water-cooled metal x-ray tube with W cathode was connected directly with the spectrometer without the interposition of any absorbing screen in the x-ray beam. The measurements were made under varying conditions. The angle of incidence being varied from 20° to 50° and the distance from grating to plate from 50 cm. to 80 cm. A weighted mean of all detns. gives the wave length of the $\text{K}\alpha$ line of C as 45.4 A. U.

BERNARD LEWIS

Visible radiation characteristics of incandescent oxides. MARCELLA L. PHILLIPS. General Elec. Co. Research Lab. Cleveland, O. *Phys. Rev.* 32, 832-9(1928).—Energy radiated in the visible part of the spectrum of various oxides and their mixts. when heated to red brightness, between 1400° and 2000° K., by means of cathode ray bombardment, and gas-air and oxy-gas flames, was measured by an optical pyrometric method. The oxides investigated were of the elements U, Ce, La, Nd, Er, Yt, Zr, Th, Al, Be, Mg and mixts. of thoria with 1% ceria (the Welsbach mantle mixt.), 1% and less of urania, 1% neodymia and 1% MgO . These were either pressed or fused to ensure good surface conditions. In general linear relations were found between the logarithm of the red-blue intensity ratio and the reciprocal of the brightness temp., and between the logarithm of the candles emitted per unit surface area and the logarithm of the brightness temp. Different modes of heating gave different radiation curves for the same oxide. Tables are given of the candles per sq. cm. and the relative blue brightness for red brightness temps. of 1400° , 1500° , 1600° , 1700° , 1800° , 1900° and 2000° K.

BERNARD LEWIS

The spark doublets in the K series. V. DOLEŽALSKÝ AND MILE. D. ENGLMANN. *Compt. rend.* 188, 318-20(1929).—It has been shown that for light elements (up to at. no. = 12) the spark doublets $\text{K}_{\alpha 3} - \text{K}_{\alpha 4}$ and $\text{K}_{\alpha 5} - \text{K}_{\alpha 6}$ are irregular doublets analogous to those of the arc, the frequency differences being const. and expressed by $\Delta\sqrt{\nu/R} = 0.007$ (for $\text{K}_{\alpha 3} - \text{K}_{\alpha 4}$) and 0.011 (for $\text{K}_{\alpha 5} - \text{K}_{\alpha 6}$). Measurements are now extended to heavier elements (at. no. = 23 to 30). The mean value of the new measurements is $\Delta\sqrt{\nu/R} = 0.0074$ in perfect accord with that obtained for the light elements.

W. F. MEGGERS

Spark spectra in liquids, the ultra-violet region. A. CAMPETTI. *Nuovo cimento* [N. S.] 5, 291-306(1928).—Spark spectra of Zn, Mg, Ca, Cu, Ag, Au, Al, Pb, Sn, Bi and Sb were measured in water and in a few cases in vaseline and CCl_4 . There are indications that the number of inverted lines increases successively with advance into the ultra-violet region. As a rule those lines are strongly inverted which correspond to the first or second resonance potential of the element. The probable assignment of the line 4226.73 not to a neutral Mg atom, but to a group contg. hydrogen is pointed out; similarly, the assignment to a group contg. oxygen for the Pb line 4057.97.

L. T. FAIRHALL

The continuous spectrum and the spectrum of the bromine arc. N. SIRACUSANO. *Nuovo cimento* [N. S.] 5, 273-83(1928); cf. C. A. 23, 767.—The Br spectrum obtained by discharge without electrodes was examd. in the region 3000-2100 A. U. By operating under controlled conditions in an atm. of very pure Br, S. was able to produce a totally continuous spectrum. The continuous band 2930 A. U. (Fowler and Strutt)

undergoes an evolution with variation in excitation corresponding to a lower level of energy than that of this band.

L. T. FAIRHALL

The continuous spectrum of mercury vapor. H. VOLKRINGER. *Compt. rend.* 188, 321-3(1929).—Heated Hg vapor may be excited in various ways and near 240° gives a continuous spectrum extending from the red region to the line at 2537 Å. U. where it terminates abruptly. Expts. with Hg at different temps. lead to the conclusion that the continuous spectrum is not due to a single carrier passing from one state to another.

W. F. MEGGERS

The spectra of doubly ionized arsenic, antimony and bismuth ($As_{II}, Sb_{II}, Bi_{II}$). R. J. LANG. Univ. of Alberta Edmonton, Canada. *Phys. Rev.* 32, 737-45(1928).—The spectra of As_{II}, Sb_{II} and Bi_{II} have been partially analyzed by the use of the irregular doublet law and the Moseley law and the published data for the two preceding elements of each isoelectronic sequence. In As_{II} and Bi_{II} ns^2np , ns^2nd , $ns^2(n+1)s$ have been located and with the exception of the quartet P term, those from the $nsnp^2$ configuration (n is equal to 4 for As_{II} , 5 for Sb_{II} and 6 for Bi_{II}). In As_{II} alone the 2P term of the np^3 configuration was found. The terms of Sb_{II} located consist of some of those for the first 3 configurations only.

BERNARD LEWIS

A study of the energy relations in the helium spectrum. I. CLYDE CORNOG. Univ. of Pa. *Phys. Rev.* 32, 746-52(1928).—Photographs of the He spectrum produced in an equipotential space with an equipotential cathode have been studied photometrically in order to det. the variation of line intensities on passing the various crit. potentials. The results here reported cover the 54.2-v. point, at which double ionization is first possible. Spectra were taken at suitable values between 50 and 60 v., often at intervals of 0.1 v. The plates show a marked max. of intensity near 54.2 v. for all lines measured.

BERNARD LEWIS

The fine structure of the sharp series triplets $2^3P_{1,1,2} - 2^3S_1$, of optically excited mercury radiation. E. HOBART COLLINS. Univ. of Iowa. *Phys. Rev.* 32, 753-60 (1928).—Measurements on the fine structure of the sharp series triplets, lines of wave lengths $\lambda\lambda 5461, 4358$ and 4047 were made with two Lummer-Gehrcke plates under two conditions of optical excitation. The first condition of optical excitation was obtained by having Hg vapor only in the resonance tube, giving excitation by absorption of $\lambda 4358$, the second by having Hg vapor with N_2 present at a pressure of 2 to 4 mm, giving excitation by absorption of both $\lambda 4358$ and $\lambda 4047$. For the first condition of excitation the wave-length differences in milli-angstroms are for $\lambda 5461$, $d\lambda 0$; for $\lambda 4358$, $d\lambda -157, -107, -20, 0, +30, +46, +183$; for $\lambda 4047$, $d\lambda -116, -62, -52, 0$. For the second condition the wave-length differences are for $\lambda 5461$, $d\lambda -235, 0$; for $\lambda 4358$, $d\lambda -107, -20, 0, +30, +183$; for $\lambda 4047$, $d\lambda -110, -62, -53, 0$. Certain fine structure energy differences of interest in the construction of energy diagrams are pointed out but it was not found possible with the data available to construct a complete energy diagram of the triplet. A comparison of the fine structure observed under the two conditions of optical excitation with one another and with the fine structure of the arc shows striking differences which make it evident that differences in fine structure exist which depend on the method of excitation.

BERNARD LEWIS

The assignment of quantum numbers for electrons in molecules. II. Correlation of molecular and atomic electron states. ROBERT S. MULLIKEN. New York Univ. *Phys. Rev.* 32, 761-72(1928); cf. *C. A.* 23, 26.—A few revisions, suggested by recent results of Herzberg of N_2^+ , were made in Part I for N_2^+ , CN and O_2^+ . These revisions involve dissocn. of unexcited mols. to give one excited atom or ion. With these revisions and a revised heat of dissocn. of N_2 , the quantum no. assignments previously made are found to be all consistent with Hund's rule of $\sigma\lambda$ and sums, and, except for one or two states of F_2 , with the $\sigma\lambda\tau$ conservation rule given in Part I. These results give needed support to the latter rule. The probable at. dissociation products are detd. for most of the mol. states given in Part I. In the case of N_2 and N_2^+ , the probable dissociation products and energies are given in tabular form in the present paper. An interpretation is given of the dissocn. processes involved in Hogness and Iunn's NO ionization potentials at 21 and 22 v., and of their 24 v. N_2^+ potential. Evidence is presented for a revision of Birge and Sponer's values of the heats of dissociation for the normal states of several mols., in particular N_2 . The suggested new or revised values are, in v., N_2 , 9.5; N_2^+ , 7.1, NO, 7.3; CO^+ , 8.3; NO^+ , 11.2. The alkali and hydrogen halides are briefly discussed, with reference to their electronic states and dissocn. products.

BERNARD LEWIS

The near infra-red vibration spectrum of the carbonates. HAROLD H. NIELSEN.

Univ. of Michigan. *Phys. Rev.* **32**, 773-8(1928).—An attempt has been made to solve theoretically the problem of the frequencies and intensities of the near infra-red absorption regions of the carbonate group. The assumption, that in the normal state the O_3 nuclei are located at the vertices of an equilateral triangle while the C nucleus lies at the center seems justified by the x-ray investigations of the crystal structure of the group. By using a general potential energy function with 3 consts. under the assumption that the fields of force surrounding the nuclei are central, the normal modes of infinitesimal vibration are detd., yielding 4 independent frequencies, $\nu_1, \nu_2, \nu_3, \nu_4$ of which ν_4 is optically inactive. Through the 3 disposable consts., ν_1, ν_2, ν_3 may be made to coincide with the 3 fundamental absorption regions found exptly. by Schaefer and Schubert (*C. A.* **11**, 913) and it is found that the optically inactive frequency ν_4 agrees closely with the predicted value. From a consideration of the change of elec. moment, the theoretical intensities are detd. It is found that the relative intensities obtained theoretically agree well with the values detd. by Schaefer and Schubert. B. J.

The spectra of mercury above the ionization potential. L. R. MAXWELL. Franklin Inst. *Phys. Rev.* **32**, 715-20(1928).—Electrons in Hg vapor with velocities greater than the ionization potential were confined to a beam by a magnetic field. The light produced was projected on the slit of a spectroscope with the direction of the beam at right angles to the slit. Perpendicular to the beam an elec. field withdrew positive ions before they recombined. The intensity of the arc lines was found to be independent of the elec. field; this indicates that recombination contributes very little to the formation of these lines. These results are contrary to the previously accepted explanation given for the complete arc spectrum appearing above the ionization potential. Consequently in addn. to simple excitation the arc spectrum can be explained in the following two ways, (1) as being due to the return to the $1S_0$ state by an electron which has been displaced from an inner energy level to a virtual orbit while simultaneously one of the electrons of the valency group falls in to fill the vacated level; (2) as due to a special type of recombination, which is called initial recombination. Spark lines due to singly and doubly charged ions show a variation of intensity along their length in such a manner that it is possible to distinguish them from the arc lines. It is also possible to differentiate between the lines of the first and the second spark spectrum. BERNARD LEWIS

The determination of the mean life for the 4797 A. U. spark line of doubly ionized mercury. L. R. MAXWELL. Franklin Inst. *Phys. Rev.* **32**, 721-6(1928).—With the method described in the preceding abstract, the spark line 4797 A. U. due to ions moving in a particular direction through a beam of electrons was obtained by the author showing a peculiar variation of intensity. Calculs. are made to det. how the intensity of the line should vary with respect to its position across the beam and for different c. d. of the beam. Cases are worked out for both uniform and non-uniform electron c. d. of the beam. On comparison with the exptl. results, it can be shown that the line is produced at a single electron impact, and that the av. life of the excited state is 4×10^{-7} sec. Although the mean life for the first-order spark lines could not be measured, it is estd. that it is less than 1×10^{-7} sec. BERNARD LEWIS

Voltage-intensity relations of 29 lines of the mercury spectrum. PAUL B. TAYLOR. *J. Franklin Inst.* **207**, 95-106(1929).—The variation of intensity of 29 prominent Hg arc lines as a function of the voltage across the arc is studied by a method of photographic photometry. The current through the arc was maintained at 4 amps; the voltage was varied from 23 to 118 v. The results are presented in tables and graphs which show that although considerable variation in the relative brightnesses of the lines occurs for a gradient below 1.5 v. per cm., above this value all lines increase in intensity in the same ratio. No explanation of these relations is attempted as the conditions of operation of the com. arc which was used were not sufficiently simple to warrant it. W. F. MEGGERS

Ultra-red arc spectra. H. AUERBACH. *Naturwissenschaften* **17**, 84-5(1929).—A table is given of band edges in the arc spectrum of La between 7876 and 8638 A. U. B. J. C. VAN DER HOEVEN

The influence of pressure and the presence of foreign gases on the absorption of excited neon. L. ECKSTEIN. *Ann. Physik* **87**, 1003-34(1928).—The intensity of absorption of several red Ne lines arising from the metastable S_1 and S_2 terms has been investigated by means of a photoelec. cell. Intensity curves giving absorption as a function of gas pressure show a max. for each wave length at 1.2 mm. Hg pressure. The addn. of He reduces the intensity slowly. H_2O , N_2 and A produce much greater diminutions. J. B. AUSTIN

The absorption spectra of praseodymium compounds at various temperatures

and different states of aggregation. RITA BRUNETTI. *Nuovo cimento* [N. S.] 5, 391-403(1928).—The absorption spectrum of compds. of Pr in dil. aq. soln., or as solids, is made up of 4 more or less wide bands distributed in the visible region from 6000 to 4000 A. U. Solns. at low temps. and equal concns. of different compds. present no great spectral differences. The relation and intensity distribution of the solid salt show no great differences in liquid air from that at room temp. The absorption spectrum of the solns. indicate the mean position of the radiation characteristic for the ion Pr^{+++} . When the concns. of the solns. is increased the wide bands which constitute their spectrum tend to take up the position at exactly those points where radiations exist in the spectrum of the crystals. L. T. FAIRHALL

Band spectra of lanthanum oxide. R. MECKE. *Naturwissenschaften* 17, 86-7 (1929).—The band spectrum of La was measured with large dispersion (3- and 6-m. concave grating) between λ 9000 and 3500 A. U. Seven band systems were found at 4372, 4418, 5600, 7380, 7403, 7877 and 7910, all are oxide spectra; they were classified. All bands are shaded toward the red. Systems 3, 5 and 7 have a common final state, also 1 and 2. The final state of 4 and 6 seems to be the initial state of 1 and 2. B. J. C. VAN DER HOEVEN

New bands of mercury hydride in the ultra-violet. HENRYK JEZEWSKI. *Bull. intern. acad. Polonaise*, Nos. 4-5A, 143-62(1928).—See C. A. 23, 1570. C. C. K.

The band absorption spectrum of cadmium vapor. ALEKSANDER JABLONSKI. University of Warsaw, Poland. *Bull. intern. acad. Polonaise* Nos. 4-5A, 163-70(1928); cf. C. A. 23, 730.—The ultra-violet absorption spectrum of Cd vapor at temps. ranging from 580° to 1020° was observed to consist of a system of bands between 2825 A. U. and 2590 A. U. The wave lengths of these new bands are listed in a table which gives for comparison the Cd bands observed in low temp. fluorescent vapor, and shows many coincidences which would indicate that these bands are connected with the dissociation of the mol. Cd_2 and the activation of one of the atoms to the 2^3P_0 state. The absorption bands appear to converge to a point near 2561 A. U., which corresponds to an energy of 4.82 v. The energy of excitation of the 2^3P_0 state is 3.78 v., which gives 1.04 v. as the dissociation energy of the Cd mol. C. C. KIESS

The origin of the band λ 2476.3- λ 2482.7 in the spectrum of mercury. ST. PIENKOWSKI. Univ. of Warsaw, Poland. *Bull. intern. acad. Polonaise* Nos. 4-5A, 171-9(1928).—The Hg band at 2476-2482 A. U. has been resolved into a system of closely spaced doublets, the wave lengths of which have been measured. These have been arranged into two branches, of which the members are separated by $\Delta\nu = 15.13 \text{ cm}^{-1}$. The sepn. of the branches is $\Delta\nu = 6.18 \text{ cm}^{-1}$. From the usual band formula a value of $3.66 \times 10^{-40} \text{ g. cm}^2$ is derived for the moment of inertia of the emitting mol. which, it is concluded, is a compd. of Hg and H. C. C. KIESS

Structure of the third-order spectrum of sulfur (S III). J. GILLES. *Compt. rend.* 188, 320-1(1929).—Continuing previous work (C. A. 23, 1570) the present note gives the classification of about 30 lines of S III lying in the ultra-violet between 2998 A. U. and 2442 A. U. They result from combinations of triplet *P* and *D* terms coming from the 4d and 5s electrons, with the triplet *S*, *P* and *D* terms coming from the 4p electron. C. C. KIESS

The triplets of helium. J. A. GAUNT. Trinity Coll., Cambridge. *Trans. Roy. Soc. (London)* 228A, 151-96; *Proc. Roy. Soc. (London)* A122, 513-32(1929).—Theoretical. C. C. KIESS

The infra-red emission spectra of flames in nitrous oxide. CHARLES R. BAILEY AND KUN-HOU LIH. Sir Wm. Ramsay Labs., Univ. Coll., London. *J. Chem. Soc.* 1929, 51-6.—A const.-deviation spectrometer with rock-salt prism was used in conjunction with a thermopile-galvanometer combination to observe the infra-red emission spectra of flames due to the combustion of H, CO, and coal gas mixed with N_2O , and of the same gases burning in an atm. of N_2O . For CO and coal gas the mode of combustion had no apparent effect on the spectrum, the spectra consisting of the emission bands of CO_2 and H_2O vapor. For H, however, when premixed with N_2O only the normal emission spectrum of H_2O was obtained. But when H alone was burned in an atm. of N_2O a new spectrum was obtained which appeared to be a combination of the H_2O emission bands with the emission analogs of those previously observed for N_2O only in absorption. C. C. KIESS

The analysis of the first spark spectrum of sulfur. D. K. BHATTACHARYYA.

Science College, Patna, India. *Proc. Roy. Soc. (London)* A122, 416-29(1929); cf. *C. A.* 22, 4064.—About 60 lines of S II, between 5646 A. U., and 3842 A. U. have been classified as members of the quartet system. To furnish data for working out the doublets new observations have been made which extend the spectrum out to 7715 A. U. in the deep red. Among these new lines are some which appear to represent inter-system combinations of the doublets with the quartets. This work led also to the discovery of a system of bands between 7574 A. U. and 7057 A. U., which closely resemble the *A*, *B*, α , α' , and α'' bands of O. The classification here given is in agreement with that of Ingram (*C. A.* 23, 36). C. C. KIESS

The ultra-violet spectrum of magnesium hydride. I. The band at λ 2430. R. W. B. PEARSE. Imperial College of Science and Technology, South Kensington *Proc. Roy. Soc. (London)* A122, 442-55(1929).—A high-dispersion quartz spectrograph was used to photograph the MgH band at 2430 A. U. The source was a Mg arc burning in H at low pressure. The band resembles closely the one at 5211 A. U. and like it has been analyzed into *P*, *Q* and *R* branches. The rotational analysis shows that the final states of both bands are the same, 2S . Both have initial states of the same type, 2P . The two systems of bands therefore result from transitions similar to those which give the first and second members of the principal series of Na, $^2P \rightarrow ^2S$. The details of the analysis are presented in comprehensive tables. C. C. KIESS

Effect of combined electric and magnetic fields on the helium spectrum. J. STUART FOSTER. McGill University. *Proc. Roy. Soc. (London)* A122, 599-603(1929).—The combined effect of parallel elec. and magnetic fields was observed for He lines belonging to the principal and sharp series of both the singlet and triplet systems and also for "forbidden" lines which appear only with a strong field. The results are in agreement with the quantum-theoretical requirement that each parallel Stark component is unaffected by the magnetic field while each perpendicular Stark component is split symmetrically into two components of equal intensity. C. C. KIESS

Secondary radiation observed by the molecular diffusion of light (Raman effect). PIERRE DAURE. *Compt. rend.* 187, 940-1(1928); cf. *C. A.* 23, 1571.—D. measures the Raman spectra of PCl_3 , $AsCl_3$, $SbCl_3$, $BiCl_3$, CCl_4 , $SiCl_4$, $TiCl_4$, $SnCl_4$ and PBr_3 ; $SbCl_3$ is measured at 100° , and $BiCl_3$ is measured in HCl soln. The Raman spectra consist generally of 4 principal lines, *a*, *b*, *c* and *d*. In the cases of PCl_3 and CCl_4 , several additional lines of smaller intensity are detectable. The characteristic frequencies decrease with the at. wt of the element linked to the halogen, but this relation cannot be expressed simply. Regarding the intensity comparison, only the negative lines are considered. In each case, the lines *a* and *c* have equal intensity. In the *P* series, *b* is about $1/4$ as intense as *a* and *c*; in the *C* series (with the exception of Ti) the intensity of the 3 lines is about equal. The intensity of *d* is variable, in general smaller than that of *c*; with $BiCl_3$, *d* is exceptionally strong. ALBERT L. HENNE

The Raman spectra of certain substances. MASAMICHI KIMURA AND YOICHI UCHIDA. *Japan J. Phys.* 5, 97-101(1928).—Preliminary data are presented on *calcite*, *water*, *neodymium ammonium nitrate*, and an untreated sample of commercial *xylene*. A fair correlation with the corresponding infra-red frequencies is obtained. Impurities in the samples are shown to give Raman lines. J. B. AUSTIN

The excitation of solid compounds by slow electrons. STANISLAW ZIEMECKI. State Technical School, Warsaw. *Bull. intern. acad. Polonaise* 1928, 367-75.—In the case of 5 substances, having especially brilliant cathode luminescence, it is experimentally found that, contrarily to accepted opinion, the excitation potential of solids by electrons is of the same order of magnitude as the excitation potential of gases. The explanation of the phenomenon is to be sought in the quantum theory. The values (in v.) actually observed were Sm 41, willemite 41, CaS 44, ZrO_2 71 and CaO 40.5. ALBERT L. HENNE

Fluorescence of mercury vapor under low excitation. LORD RAYLEIGH. *Nature* 123, 127(1929); cf. *C. A.* 23, 1058.—The Hg fluorescence has been studied by means of longer effective exciting wave lengths. The source was a Ni arc, with a filter of salicylic acid, which cuts off completely all waves shorter than 3360 A. U. The spectrum consists of the 2 well-known broad maxima, the green fluorescence and the ultra violet 3130 to 3650. The latter, which has never been resolved, was not yet resolved by the present excitation applied near the middle of the band. The continuous fluorescent spectrum extends about 300 A. U. beyond the limit of the exciting spectrum, a set by the sharp cut of the filter. G. CALINGAERT

Connections between the photochemical reaction velocities and the fluorescent of organic compounds. G. KÖCKE. *Z. wiss. Phot.* 26, 311-9(1929).—The fluorescent

of aromatic compds. with complete closed rings is the indication of a potential photochem. light sensitivity; with the derivs. of satd. aliphatic and aliphatic-aromatic compds. it is a sign of actual photochem. light sensitivity. A. P. H. TRIVELLI

Induction period and after-effect in photochemical reactions. RUKMINI MOHAN PURKAYASTHA. Dacca Univ. *J. Indian Chem. Soc.* 5, 721-32(1928); cf. *C. A.* 20, 870, 1953; 22, 1151 4379.—Bromination of cinnamic acid (I) and stilbene (II) in both CS_2 and CCl_4 in green light at 30° or 40° shows an induction period which is diminished by an increase in temp. or in the intensity and frequency of the incident radiation. In the oxidation of tartaric acid (III) by Br_2 , the induction period increases with increase in the concn. of III; with increase in the concn. of Br_2 , it increases to a max. and then diminishes. In the oxidation of mandelic acid (IV) and of β -phenyllactic acid (V) by Br_2 at 25° there is no induction period in the dark; in light there is a period of induction and also an after-effect when the source of light is withdrawn. If KBr in a concn. 8 to 10 times that of the Br_2 is added to mixts. of III or IV and Br_2 before exposure to light, the induction period completely disappears or is considerably reduced. P explains the results as follows. In the bromination of I and II the induction period is due mainly to the formation of intermediate complexes; in the oxidation of III by Br_2 it is due to photo-inhibitors and to the hydrated state of the Br_2 mols.; in the oxidation of IV and V, it is due to the hydrated Br_2 mols. LOUISE KELLEY

Theoretical speculations on photolysis of silver halide with regard to the quantum theory and the photoelectric effect. H. KIESER. *Z. wiss. Phot.* 26, 275-87(1929).—In connection with the detn. of the quantum absorption for the photolysis of the pure AgBr and the new theories of Fajans the chem. reaction caused by the photoelec. effect is discussed. A characteristic result of this investigation is the hypothesis that the photolysis of the Ag halides concerns a system that gives sep., scattered, halogen atoms. The chem. reaction is discussed and a scheme is built up for the photolysis of pure AgBr , for AgBr in H_2O , in NaNO_2 soln., in AgNO_3 soln., and in gelatin. By means of this theory it is possible to explain regression, coagulation, Becquerel effect, and photo-mechanical disintegration. A. P. H. TRIVELLI

Surface layers on tungsten and the activation of nitrogen by electron impact. CARL KENTY AND LOUIS A. TURNER. Princeton Univ. *Phys. Rev.* 32, 799-811(1928).—A fine W filament at 400° in active N_2 is quickly covered with a layer which produces a lowering of the resistance of the filament. This lowering of the resistance is apparently the result of a lowering of the temp. of the filament because heat is more readily conducted away from the coated filament by the gas than from the clean filament. At a given temp. 15-20% more heat is conducted away by the gas with the layer present. The same effect is produced by activating the N_2 by electron bombardment. In a tube with a large Ni anode the production of the active agent could be detected down to 10.8 ± 0.5 v. In a tube with a hot W spiral anode of small area the effect could be detected down to the ionization potential, 16.3 v. Traces of O_2 cause the spontaneous formation of a layer which renders the filament insensitive to active N_2 . Traces of H_2 prevent the formation of the N_2 layer and remove it if already present. Expts. with a tube of small vol. contg. Ni disks of large area show that the amt. of N_2 absorbed is of the order of magnitude of the quantity required to produce a layer of single atoms. Activation of a stream of N_2 reduces the thermionic emission from a W filament in the stream. Similarly, the striking of an arc in N_2 under suitable conditions gives a momentary slight increase of current followed by a great decrease, the emission apparently being cut down by the active form of N_2 produced in the arc. Upon subsequently breaking off the same arc by reducing the anode voltage the current drops and then quickly rises to its much higher former value, at that voltage. With an interrupted arc in pure N_2 , and in A contg. a small percentage of N_2 , an emission of the D lines persists for several hundredths of a sec. after the extinction of the arc. The Na is evapd. from an oxide-coated filament and excited by some active form of N_2 produced in the arc, presumably at N. BERNARD LEWIS

The measurement of the life of excited sodium atoms from the brightness of the sodium flame and the degree of dissociation of sodium salts in the flame. R. LADENBURG AND R. MINKOWSKI. *Ann. Physik* 87, 298-306(1928).—Measurements previously made on the life period of activated Na atoms by dispersion did not agree with results obtained by others from a study of the Na flame. This was believed due to the assumption that Na atoms in the flame were totally activated. Assuming that Na from any salt such as NaCl or Na_2CO_3 passes through the stage of NaOH in a flame, L and M. show from data on NaOH that results on the life of excited Na atoms were actually about those previously obtained by them from dispersion measurements. Therefore not all the Na is in an excited state in a flame. RAYMOND H. LAMBERT

Treating liquids with ultra-violet rays. HERMANN SCHOLL. Fr. 646,792, Dec. 28, 1927. Liquids to be treated with ultra-violet rays are freed from air, to prevent formation of ozone, by passing a gas through the liquid which will displace the air. Cf. C. A. 22, 4015.

Treating galena crystals for detectors. A. S. ZATEISHCHIKOV. Russ. 5411, May 31, 1928. The galena crystal placed in a spoon is first wetted with 20° Bé. H_2SO_4 , then sprayed with $K_2Cr_2O_7$ powder and heated until this is melted and until the development of oxygen has ceased. Then the crystal is cooled and the crust removed.

4—ELECTROCHEMISTRY

COLIN G. FINK

The energy losses of a seven-ton Héroult furnace with special reference to the heat-storing features. N. WARK. *Arch. Eisenhüttenw.* 2, 145-50(1928).—Investigations to det. the thermal cond. and accumulation of heat in the brick work of a 7 ton Héroult furnace, having graphite electrodes 250 mm. in diam. and fed from a 2000 kv. amp. transformer; 180 v. during fusion and 104 v. during finishing were used. When better scrap is used, or the condition of the brick work is better, or the time of charging is smaller, there is less cooling off of the furnace and therefore smaller heat-cond. and radiation losses. The accumulation of heat begins during the refining period and reaches a max. in the middle of the finishing period, decreasing from this point on. During the fusion period the brick work aids the heat supply; afterward the accumulated heat accelerates the melting. The heat balance of the furnace is detd. J. BALOZIAN

The energy losses of a fifteen-ton Héroult furnace with special reference to the life of the roof. H. KLINAR, O. REINHOLD AND N. WARK. *Arch. Eisenhüttenw.* 2, 151-3(1928).—The heat balance and the effect of the wearing away of the roof on the energy losses of a 15-ton Héroult furnace are detd. Graphite electrodes 350 mm. in diam., a 5000 kv. amp. transformer, 183 v. during fusion and 104 v. during finishing were used. The radiation losses of the roof are 8% higher toward the end of the melt than at the beginning. The heat accumulated in the roof brick confirms data detd. for the 7-ton furnace (see preceding abstract). Fusions are made using liquid Siemens-Martin steel (freshly tapped) to det. the exact energy losses in the 15-ton furnace. The ratio *heat in steel/total heat input during fusion* is greater with the liquid than with the solid charge. About 6% of the heat introduced by the elec. current is used for raising the steel temp., the remainder being consumed in the formation of the slag and in radiation and conduction losses. Of the total heat expended, 4.5% is used for the slag and about 13% for the combined cond. and radiation losses. J. BALOZIAN

An electrolytic refining process for nickel. B. BOGIRCH. *Compt. rend.* 188, 328-9(1929).—Anodes contg. about 10% of Cu, Fe, C, S, As and O yield cathodes contg. 99.9% of Ni plus Co. A two-compartment cell is used. The electrolyte, a soln. of $NiCl_2$ of sp. gr. 1.2, flows from the cathode chamber to the anode chamber, and thence to a purification tank, where $Ni(OH)_2$ is added to ppt. Fe, As, Co, etc. The temp. is kept at 65°. Some of the Cu remains with the anode mud, but the bulk must be removed by a special (undescribed) electrolytic process. The deposit peels from plane starting sheets, but satisfactory results are obtained by plating on pure nickel wire 0.5 mm. in diam. The cathodes are removed in the form of bars 50-60 cm. long and 15-20 mm. in diam. After a softening annealing they are cut into small cylinders. The Ni salt held by the filter cake is used to prepare the nickelic hydroxide. The

method of prepn. is not given, nor are the c. d., energy consumption, materials of construction, treatment of anode mud, etc.

BENJAMIN MILLER

Electrolytic zinc refining. II. The influence of foreign elements upon the hydrogen overvoltage. HIROTA SETO. Akita Higher Tech. School. *Hokko* 24, 1-22(1928).—S. has already examd. the influence of addn. agents on the deposition of Zn from its H_2SO_4 soln. The current efficiency of the anode then studied is now investigated. The method of measurement was a direct one, working at 25° , 1-100 milliamp./cm.². As a preliminary expt. the relation between the overvoltage of Pt, Cu, Fe, Pb, Zn, Cd, Ni and Co in 2 N H_2SO_4 and their surface condition was examd. Bright and platinized Pt was used, and the other metals were plated in turn on the Pt electrode. The result shows that there is no great difference in the overvoltage when the plated surface is smooth or cryst., while the overvoltage obtained with spongy Pt, spongy Ni and platinized Pt is very much smaller, which fact is attributed by S. to the differences in adsorption capacities. To exam. the influence of the added reagent upon the H_2 overvoltage 2 kinds of expts. were made. In the first, the influence of added reagent upon the soln., or the "direct" influence was studied, and in the second, its influence upon the phys. properties of deposited Zn, or the "indirect" influence. In the first expt. it was found that gelatin and cinchonine (addn. agents) function to make the H_2 overvoltage larger. To see whether there is some close relation between the effect of making the overvoltage larger and the surface tension, gelatin, dextrose-cinchonine, AcOH and $MgSO_4$ were added to the soln., but no conclusive results were obtained. To exam. the "indirect" influence, 0.01, 0.16, 0.32% of gelatin, dextrose and tannin were added to the soln. contg. 188 g. of $ZnSO_4$ per l. The overvoltage obtained at the surface of Zn deposited from the above soln. was always found to be smaller than when measured with pure Zn, the difference being most marked when gelatin was added. Since the crystal growth in the deposited surface is not very good, S. supposes that the gas adsorption on the surface is small, hence the small overvoltage. Between the "direct" and "indirect" influence, the latter influence is the greater. K. S.

Electrolytic preparation of "distilled" water. OSWALD GERTH. *Chem.-Ztg.* 53, 52-3(1929).—One or many electrolytic cells, divided into 3 compartments by porous diaphragms, provided with anodes and cathodes in their outer compartments and fed with raw water in the middle compartment, cause the impurities to gather in the outer compartments and purer water to be left in the middle one. By suitable arrangement continuous purification is possible; plants have been built to give 3 to 250 l. of purified water per hr. The current used is about 3-4 kw. hr. per 100 l. W. C. EBAUGH

The electrochemical manufacture of hydrogen peroxide. LEO LÖWENSTEIN. *Z. Elektrochem.* 34, 784-6(1928).—Correction to C. A. 23, 1061. "In the other process a soln. of NH_4HSO_4 [not NH_4HSO_3] is electrolyzed. The $(NH_4)_2S_2O_8$ soln. formed is treated with $KHSO_4$ [not $KHSO_3$], which ppts $K_2S_2O_8$ and regenerates the NH_4 salt. The ppt. is charged into a stone-ware still contg. H_2SO_4 , and superheated steam is blown through the mass. H_2O_2 vaporizes and $KHSO_4$ [not $KHSO_3$] is regenerated."

BENJAMIN MILLER

The control of current density in plating baths. W. PFANHAUSER. *Chem.-Ztg.* 53, 129-30(1929).—The thickness of the deposit is almost always specified in present-day plating practice. Since thickness depends on c. d. and time, a knowledge of the current density is essential to proper plating. But when work of complicated shape is being done, or when various articles are being plated at the same time, it is difficult or impossible to get the current density from the ammeter reading and from the measured cathode surface. Actually, the current density and the deposit thickness vary from point to point on the cathode surface. But the work must be done so that no part gets less than the specified thickness. To meet this situation the Langbein-Pfauhauser Company has introduced the c.-d. meter. This consists of two circular disk electrodes, each about 0.5 dm.² in area, mounted in a hard-rubber case with their plane faces parallel, and insulated from each other except for wires leading to a small meter in the handle. When the instrument is placed in the bath with the side marked A facing the anode and the side marked K facing the cathode, it reads directly in amperes per square decimeter. The meter must be calibrated for the soln. in which it is to be used. It may be moved from place to place in the bath, and shows the current density which obtains in each region. The scale may be calibrated in minutes to get a certain thickness, say 0.025 mm. for nickel baths. In addition to its use in controlling thickness, the instrument warns of excessive current densities, which may cause harmful hydrogen evolution. It is also helpful in keeping within a current-density range which gives desirable surface effects, such as the bright plate range for Cr. BENJAMIN MILLER

The calculation of the theoretical potential of potassium and sodium. P. DROSS-

BACH. *Z. Elektrochem.* 35, 95-6(1929); cf. *C. A.* 23, 42.—By correcting his former calcs. of the theoretical potentials for the degree of dissociation as detd. by cond. methods, D. obtains the following values $\epsilon_K = -2.97$ or -2.96 v.; $\epsilon_{Na} = -2.72$ v.

MALCOLM DOLE

New electrochemical processes. JOHANNES BECKER. *Chem. Fabrik* 1929, 49-51.—The Siemens and Halske system for removing salts from water electrically is briefly described (cf. *C. A.* 23, 459). App. for the production of ozone is now available in sizes up to 300 kw., with capacities up to 10-12 kg. of O_3 per hr. Concns. of 2-4 g. of O_3 per cu. m. can be obtained in air or oxygen, with an energy consumption of 25-35 kw. hrs. per kg. of O_3 . A new use for O_3 is in the accelerated aging of liquor. Treatment of liquor with O_3 gives a mellowing effect in a short time which requires months or years of storage. Analysis shows decreased aldehyde content and increased ester content. The ozonized liquor is more bland. For liquor treatment a special 50-watt ozonizer is furnished, with a capacity of 100 l. per hr. Now that Ta can be obtained in large pieces, it has been found useful for many chem. purposes.

Metallurgy of Al (FERRERI) 9. Electricity and the chemical industries (GIBB) 13. The transfer of matter in the Fe arc (SCHMICK, SEELIGER) 2. The influence of size on insulator strength (ROWLAND) 19. Electric furnace for melting glass (Brit. pat. 295,713) 19. Tin (Brit. pat. 295,805) 9. Alarm device for indicating heating of oil-insulated electric transformers, etc. (U. S. pat. 1,705,715) 1. Cu_2O on Cu (U. S. pat. 646,408) 9. Ornamental effects on metal surfaces (Brit. pat. 295,889) 9.

Electric battery. A. M. CODD. Brit. 295,743, May 18, 1927. Structural features are specified relating to a battery with a Zn electrode and with an electrolyte of $FeCl_3$ the cond. of which may be increased by the addn. of NaCl, KCl, or NH_4Cl .

Electric battery. OLDHAM & SONS, LTD., and W. D. WILDE. Brit. 295,746, Sept. 1, 1927. Structural features.

Electric batteries. A. HELBRONNER and E. DUTT. Brit. 295,589, Aug. 11, 1927. An insol. ferrocyanide, such as the ferrocyanide of Zn, Cu, or Ag, is used as a depolarizer in wet- or dry-cell batteries, alone or mixed with "carbon, coke, or graphite."

Electric batteries. WILLIAM E. KERSHAW and JOSEPH L. WOODBRIDGE. U. S. 645,935, Dec. 20, 1927. An element adapted to exercise a counter e. m. f. comprises electrodes of Ni in an electrolyte consisting of a soln. of an alkali hydroxide and a sol. chromate.

Primary electric-battery. MARTIN L. MARTUS, EDMUND H. BECKER and JAMES G. ROSS. U. S. 1,706,895, March 26. Structural features.

Centrifugal production of primary electric-battery elements. J. S. CROSLLEY. Brit. 295,219, April 4, 1927. Plastic material (which may comprise C, graphite and a binder such as molasses, flour, oil, tar, an alc. resin soln. or the like) is placed in a rotating mold, which may form a part of the electrode or may be of an easily destructible material such as paraffined cardboard. A cylindrical Cu electrode may have deposited on its inner surface a layer of Cu oxide, graphite and a binder such as whiting or Na silicate. $MgCl_2$ or $FeCl_3$ may be added to the Cu oxide, and the mixt. heated to form an oxychloride. Various structural features of the battery are described.

Dry batteries. ELECTROCHIMIQUE PHOSBUS. Fr. 646,460 and 646,461, May 18, 1927. Constructional details.

Dry-cell electric batteries. BATTERIEN- UND ELEMENTE-FABRIK SYSTEM ZEILER A.-G. Brit. 295,841, Sept. 7, 1927. Structural features.

Storage battery. F. STAME. Brit. 295,584, Aug. 13, 1927. In a battery having a neg. electrode, which on charging receives a deposit of Zn, Ni, Ag or the like, the electrode is enclosed in a bag of fabric or other porous material to prevent short-circuiting due to the formation of metallic burrs or projections. Various structural details are specified.

Storage batteries. J. S. CROSLLEY. Brit. 295,220, April 4, 1927. Centrifugal action is used to effect deposition or shaping of materials used in storage-battery construction. Separators comprising asbestos or pulp may be shaped by centrifugal de-

position, or the separators may be formed of asbestos sheeting soaked in Na silicate soln. and then dipped in acid such as H_2SO_4 to ppt. silica. The paste deposited on the plates may be formed from pptd. Pb mixed with PbO or Pb_2O_3 and Pb wool, or of other compns. suitable for use with grids of Pb, Zn and Pb, Cu and Pb, Cu and Zn, Ni and Fe, or other materials. Various structural details are described.

Storage batteries. ADOLFO POUCHAIN. Fr. 645,924, Dec. 19, 1927. Construction of neg. electrode.

Storage batteries. JACQUES DELPECH and EUGÈNE VACHERON. Fr. 645,933, Dec. 20, 1927.

Storage battery suitable for use with miners' lamps. CONCORDIA ELEKTRIZITÄTS-A.-G. and W. GOSMAN. Brit. 295,561, March 19, 1928. Structural features.

Galvanic cell. K. I. CHETIRKIN. Russ. 5459, May 31, 1928. A cell of the Feri type, with air depolarization and with a zinc electrode located horizontally on the bottom of the container, is characterized by a cylindrical carbon electrode open on both ends to have free access of air which is led through the bottom and the cover of the container.

Dry galvanic cell. K. I. CHETIRKIN. Russ. 5460, May 31, 1928. In a dry cell the Zn electrode is on the bottom and the plate-shaped carbon electrode forms the cover to increase the contact with the air.

Battery of galvanic cells. G. M. REZNIKOV. Russ. 5456, May 31, 1928. An arrangement is specified for filling and discharging all cells simultaneously with a liquid electrolyte.

Rectifiers. FANSTEEL PRODUCTS CO., INC. Fr. 646,749, Jan. 6, 1928. An electrolyte used in electrolytic rectifiers contains a small amt. of a Co salt, e. g., $CoSO_4$ in dil. H_2SO_4 .

Electric rectifiers with copper disks and cuprous oxide coatings. P. H. GEIGER (to Westinghouse Brake & Saxby Signal Co., Ltd.). Brit. 296,077, Aug. 25, 1927. Structural features.

Materials for alternating-current rectifiers. L. ST. C. BROUGHALL. Brit. 295,194, Feb. 17, 1928. An oxide layer is formed on Cu by heating it in an atm. of N_2O . The heat ng is regulated to avoid CuO production and is continued until the layer of Cu_2O formed is in a cryst. state; cooling is effected in 2 stages, first slowly to avoid cracking off of the oxide layer and then more rapidly (suitably in water or oil). Any small particles of CuO are removed chemically or mechanically before the rectifier elements are assembled.

Electrolytic rectifier. GLEN D. BAGLEY and FRED T. BOWDITCH (to National Carbon Co.). U. S. 1,706,950, March 26. An electrolyte contg. citric acid or a citrate is used with electrodes, one of which is formed of Al and the other with a conductive solid metal oxide such as PbO_2 .

Electrolytic rectifier. RAYMOND C. BENNER (to National Carbon Co.). U. S. 1,706,951, March 26. An electrolyte comprising H_2SO_4 (suitably of 1.25 sp. gr.) is used with electrodes, one of which comprises Ta and the other graphite coated with PbO_2 .

Apparatus for electrodeposition of thin layers of metals on rotating cathodes. E. KELSEN. Brit. 296,060, Aug. 24, 1927.

Electrodeposition of metal in manufacture of sound records. GRAMOPHONE CO., LTD., and S. WHYTE. Brit. 295,767, May 24, 1927. A pos. or neg. matrix for use in the manuf. of sound records is prepd. by electrodeposition on a metal matrix of opposite character, which has been covered with a film of Ag or other metal by a replacement process to render the subsequent deposit readily detachable; e. g., a Cu pos. is immersed in a soln. formed of $AgNO_3$, NaCN and water; a soln. of $HgCl_2$, NaCN and water may be used instead of the Ag soln.

Electrodeposition of chromium. RUDOLF AUERBACH (to Chromeplate, Inc.). U. S. 1,705,954, March 19. Freshly formed silicic acid is added to an electrolyte contg. chromic acid in order to permit a greater range in the c. d. which may be satisfactorily used.

Electroplating apparatus. RICHARD BLASBERG. Ger. 471,259, Nov. 25, 1926. Improvements are described in an app. of the kind in which supporting bars for the goods and the anode are reciprocated longitudinally over bath.

Rotating barrel apparatus for electroplating small articles. W. CANNING & CO., LTD., and G. A. POPE. Brit. 295,791, June 18, 1927. Structural features.

Electrogalvanizing apparatus. PETER JEPSEN (to American Steel and Wire Co. of N. J.). U. S. 1,706,520, March 26. Structural features of an app. suitable for electrogalvanizing wire.

Electrolytic cell. ELEK. A.-G. VORMALS SCHUCKERT & Co. and FRANZ PETZ. Ger. 469,328 and 469,329 of Nov. 25, 1927 and 469,300 of Dec. 4, 1927; addns. to Ger. 410,772. The cell is made of reinforced concrete and in the inner walls between the electrodes, hollows are formed for the admission of a cooling medium. A cooling jacket may also be added. The bottom and side walls are reinforced by U-shaped struts with the interstices packed by asphalt, paraffin wax, pitch, or similar substance. The cell is split up by porous diaphragms into chambers, each of which contains a pos. plate. The neg. plates embedded in the base are connected in pairs by a conductor on each side of the center pos. plate.

Apparatus for electrolytic mass production. LANGBEIN-PFANNHAUSER-WERKE A.-G. Ger. 471,260, Feb. 21, 1926. Means are described for conveying articles through a series of plating, rinsing, etc., baths.

Electrolytic precipitation of iodine from solutions. S. V. KONSTANTOV and G. G. URAZOV. Russ. 5305, May 31, 1928. Copper electrodes are used.

A bath for an electrical precipitation of tin. G. F. KOMOVSKII. Russ. 5367, May 31, 1928. Tin chloride is heated with phenol in the presence of HCl, and the complex compd. formed is dissolved in water.

Maleic and succinic acids. FIRMA ZAIDAN HOJIN RIKAGAKU KENKYUJO. Ger. 469,234, May 18, 1926. These acids are prepd. by the electrolytic oxidation of furfural in a soln. of acid or salt or in the powd. form. Pb electrodes are used.

Electric resistances. T. D. PARKIN. Brit. 295,444, May 13, 1927. Various structural details of resistances for rheostats, etc., are given. The molded portions may be formed of a phenolaldehyde product, and the conducting material may be graphite, preferably the kind known as "Dag" suspended in a liquid, which is brushed or sprayed on a metal plate. To give a very high resistance the graphite may be suspended in an insulating varnish or mixed with colloidal clay. Metallic films of Ag or Pt deposited on a pressure plate may be used and the latter may be faced with silica, glass, or mica.

Electric-resistance heating units for cooking plates or similar apparatus. EDWIN L. WIEGAND (to Edwin L. Wiegand Co.). U. S. 1,706,015-16-17, March 19. Structural features.

Electric-resistance heater for immersion in liquids. EARL S. NEAL. U. S. 1,705,835, March 19. Structural features.

Electric furnaces, resistance heaters and ovens. JAMES C. WOODSON (to Westinghouse Elec. & Mfg. Co.). U. S. 1,705,696-7-8, March 19. Structural features.

Electric-resistance furnace. ORA A. COLBY (to Westinghouse Elec. & Mfg. Co.). U. S. 1,705,717, March 19. Structural features.

Electric-resistance furnace. ROBERT J. WALKER. U. S. 1,706,010, March 19. Structural features.

Electric-resistance furnace. H. WIGGIN & Co., LTD., and A. G. LOBLEY. Brit. 295,299, April 8, 1927. A construction is described in which the resistances are supported by hooks detachably mounted in insulators on a metal frame. Cf. C. 1 22,432.

Electric-resistance furnace. GOTTFRIED TRÖMLER. Swiss 128,314, May 1, 1927. The outer wall is built up of several coaxial tubular sections fitting round the heating element, which contains the electrodes and closed rings. Inside the heating element is a rotary metallic drum for the ore with insulated bearings.

High-frequency electric furnaces. RENÉ DUFOUR. Fr. 646,524, Dec. 20, 1927.

Electrically actuated furnace control operating in accordance with the composition of the flue gases. SIEMENS & HALSKER A.-G. (Wilhelm Liesegang, inventor). Ger. 471,379, Dec. 22, 1926.

Automatic regulator for electric furnaces. DONALD F. CAMPBELL, GEORGE E. TAYLOR and ELECTRIC FURNACE Co., LTD. Fr. 645,962, Dec. 20, 1927.

Furnace electrodes. GEBRÜDER SIEMENS & Co. Fr. 646,143, Dec. 24, 1927. The electrode mass is compressed by shaking in a metallic sleeve.

Furnace electrodes. NORSKE AKTIESELSKAB FOR ELEKTROKEMISK IND. Fr. 646,310, Dec. 7, 1927. A non-metallic casing, such as one made from graphite and oil, is used for the production of electrodes which are burned during use in the elec. furnace.

Cleaning electrodes such as those of electrolytic condensers. HUMPHREYS O. SIGMUND (to Western Elec. Co.). U. S. 1,705,944, March 19. Electrodes are immersed in an unsatd. KOH soln., rinsed with water, immersed in a bath of dil. HNO₃ and HF, and again rinsed with water, in order to facilitate rapid formation of a dielectric film of good resistance on the electrodes.

Assembling sheets of electrical condensers. GREENLEAF W. PICKARD (to Wire-less Specialty Apparatus Co.). U. S. 1,706,816, March 26. In assembling non-porous dielectric sheets of materials such as mica with metal sheets, the surfaces of the former

are preliminarily coated with a dielectric detergent liquid such as hot paraffin which, when the sheets are assembled and pressed together, serves to force out air and moisture.

Electric spark-gap oscillation generator. J. E. SCHEEL and W. H. BULL. Brit. 296,067, Aug. 24, 1927. Various details are given of an app., the main electrodes of which are preferably formed of Cu coated with W on the inner faces, with an auxiliary electrode of wire, net, or point construction.

Hydrometer with spaced concentric tubes. FREDERICK C. JEWELL and HENRY S. JEWELL. U. S. 1,706,234, March 19. Structural features of a hydrometer suitable for testing the electrolyte of storage batteries.

Temperature indicator for electrical apparatus such as transformers. SAMUEL HORELICK (to Pittsburgh Transformer Co.). U. S. 1,706,609, March 26. A thermometer is formed with a bulb of insulating refractory material such as glass; a section of tubing of about the same coeff. of expansion as the refractory material is imbedded in the thermometer to form an airtight joint, and a metal tube such as Pt is secured at the outer end of the tubing.

Electric liquid heaters. WILFRED Y. NEWLAND. Fr. 646,740, Jan. 6, 1928.

Electrothermal reduction. SOC. ÉLECTROMÉTALLURGIQUE DE MONTRICHER (Soc. anon.). Fr. 646,874, Jan. 9, 1928. The electrothermal reduction process of Fr. 606,428 is extended to Si alloys, particularly Si-Al alloys, the metallic Fe in the conducting part of the fusion beds being replaced by oxidized Fe, pure or mixed. Cf. C. A. 23, 1578.

Steel. FONDERIA MILANESE DI ACCIAIO. Fr. 646,726, Jan. 5, 1928. Steel is produced in an elec. furnace into which is charged molten cast iron obtained by fusion of waste iron, etc., in a suitable cupola furnace. The no. of furnaces is arranged so that the whole functions without interruption.

Removing cupric oxide. HANOVIA CHEM. & MANUF. CO. Fr. 646,410, Dec. 27, 1927. CuO is removed from a surface of Cu or Cu₂O by placing the surface in a bath contg. dil. H₂SO₄ and an acid sulfate, and passing a direct or alternating current through it. The CuO may afterward be washed off with water.

Conductive cuprous oxide. SIEMENS-SCHUCKERTWERKE. A.-G. Fr. 646,427, Dec. 28, 1927. Cu₂O is formed on metal to produce Cu-Cu₂O rectifiers by heating the latter in an atm. in which the partial pressure of the O is reduced to an amt. which does not exceed the dissocn. pressure of the oxide at the reaction temp. The temp. used is considerably below the f. p. of the metal.

Treating substances with ozone. EDMOND BÉGOT. Fr. 646,776, May 20, 1927. Liquids or powders to be treated with ozone are caused to circulate in the elec. discharge itself which produces the ozone.

Nickel alloys. W. S. SMITH, H. J. GARNETT and J. A. HOLDEN. Brit. 296,112, April 25, 1927. In refining alloys contg. over 50% Ni the furnace charge is melted in the presence of a slag and H or other reducing atm. to avoid the presence of S. The alloys may contain Fe, Cr, W, V, Mo, Si, Al, Cu, Co, Ti or Zr, and the slag may be formed of lime and silica with a small quantity of fluorspar or CaCl₂. The refining is preferably effected in an elec. furnace of the induction type. Finishing agents such as Mg may be added, various details of procedure are described.

Vibrating electrode in electrical dust precipitation apparatus. LODGE-COTTRELL, LTD. (Metallbank und Metallurgische Ges. A.-G.). Brit. 295,890, Dec. 22, 1927.

Electric gas-purification plant with large-surface precipitation electrodes. SIEMENS-SCHUCKERTWERKE. A.-G. Fr. 646,736, Jan. 6, 1928.

5—PHOTOGRAPHY

C. E. K. MEES

Some properties of photographic films. F. WEIGERT and F. LÜHR. Z. Elektrochem. 34, 605-10(1928).—W. and L. have studied the effect of chemically reduced Ag caused by gelatin and of photosilver on light sensitivity of photographic films. Ag concn. is measured by electrometric titration by the differential method for which an accuracy of 0.003 mg. Ag in a gelatin-soln. medium is claimed. The original Ag (chemically reduced) increases with time of digestion. Photosil-er shows autosensitizing with digestion. Comparisons were made of films treated with K₂S₂O₈ and others treated with H₂O₂; it was found that light sensitivity increased with increase of original Ag. Increase in original Ag with time of digestion is dependent on the Ag halide, increasing in the order, iodide, bromide, chloride. The nature of the sensitizing depends greatly on the disperse condition of the system, and the suggestion is made that addns. such as dyes

may entirely change the property of emulsions contg. a given amt. of original Ag.

R. H. LAMBERT

Developing properties of the meta derivatives. A. LUMIÈRE, L. LUMIÈRE AND A. SEYEWETZ. *Sci. Ind. Phot.* 8A, 37(1928); *Bull. soc. franç. Phot.* 15, 90-2(1928) — The meta derivatives of the di-phenols have been considered as having no developing properties. This conception has been based largely on the fact that compounds such as resorcinol, orcinol, metaphenylenediamine and metaaminophenol possess no developing properties while the ortho and para compds. are developing agents. Homolka has proposed a theory to explain in the case of resorcinol the absence of developing properties by indicating the ease with which resorcinol undergoes tautomerism under the influence of alkali to form a di-acetone. By substituting methyl groups adjacent to the hydroxy groups to prevent tautomerism the resulting compd., mesoresorcinol, becomes a developer. The Lumières and Seyewetz have attempted to apply Homolka's theory to the behavior of dimethyl metaaminophenol and to dimethyl metaphenylene diamine, but were unsuccessful. When methyl groups are substituted in these compds. adjacent to the hydroxy or amino groups, the resulting compds. are not developers. Although the authors have confirmed that mesoresorcinol is a developer, they are at a loss to explain by Homolka's theory the action of metaaminophenol and diaminophenol.

C. E. K. M.

Intermediate regression. LÜPPO-CRAMER. *Z. wiss. Phot.* 26, 295-9(1929) — A photographic plate exposed under an Eder-Hecht scale until solarization occurs shows an intermediate Herschel effect under the red filter, which can be isolated if the plate is treated with NaNO_2 before exposure. Then all solarization is eliminated. The red rays serve as a protective medium for the Herschel effect. To explain this effect, L. C. refers to the possibility of an intermediate regression as proposed by S. E. Sheppard and A. P. H. Trivelli (*Phot. Korrr.* 64, 145(1928)).

A. P. H. TRIVELLI

BULLOCK, EDMUND R.: Chemical Reactions of the Photographic Latent Image. New York: D. Van Nostrand Co., Rochester, N. Y.: Eastman Kodak Co. 178 pp.

CLARK, WALTER: Données numériques de photographie. A Chapter from Vol. VI of *Données numériques*. Paris: Gauthier-Villars et Cie. 36 pp. Stitched, F 20. bound, F 36. Reviewed in *J. Sci. Instruments* 6, 80(1929).

WHEELER, OWEN: Colour Photography. New York and London: I. Pitman & Sons, Ltd. 138 pp.

Theoretical speculations on photolysis of Ag halide with regard to the quantum theory and the photoelectric effect (KIESER) 3.

Photographic processes. KALLÉ & Co. A.-G. *Brit.* 296,008, Aug. 22, 1927. Tanned colloid images are produced by exposing to light, under a negative or diapositive, a diazo compd. coated upon a base, and subjecting the colloid layer, in the presence of the image thus formed, to the action of a chromate or other oxidizing agent such as NH_4 hypobromite, or of a diazo compd. of great coupling capacity. Numerous details, examples and modifications of procedure are described.

Photographic transfer process. J. LAGENDYK. *Brit.* 295,345, May 9, 1927. In order to transfer a photograph printed on an emulsion layer from a paper support to a deed, passport, or other document so that reading matter of the document may show clearly through the photograph when the temporary paper support is stripped off, the wet photograph is placed face down on the document, pressed under heavy pressure after removing air bubbles, and treated with steam to facilitate stripping of the paper support and union of the picture with the document. A hardening bath may be used to permit rapid drying.

Photographic diazotype process. F. VAN DER GRINTEN (trading as Chemische Fabriek L. van der Grinten). *Brit.* 295,993, Aug. 22, 1927. Diazotype prints are developed by applying a suitable alk. developer in a very thin uniform layer simultaneously over the whole width of the image to be developed. An app. is described and numerous details of procedure and formulas of solns. used are given. Cf. C. A. 23, 1832.

Photographic films. NIKOLAUS LEDENKO. *Fr.* 646,484, Dec. 28, 1927. Films of gelatin, etc., are sensitized by solns. such as dichromate used more concd. than usual, e. g. 6%, after which the film while still damp is dipped for a short time in pure water or in a 2% dichromate soln., whereby formation of crystals at the surface is prevented.

Photographic films. I. G. FARBERND. A.-G. *Fr.* 646,157, Dec. 24, 1927. Films are rolled with 2 sep. protecting papers, e. g., a red and a black.

Photographic films, etc. SOC. CIVILE POUR L'ÉTUDE DE LA PHOTOGRAPHIE ET DE LA CINÉMATOGRAPHIE EN COULEURS. Fr. 646,202, May 6, 1927. A sensitive film or plate for color photography of the kind reticulated on one of its faces is formed of a layer of material sensitized within its mass, which may be used alone or have a support of celluloid, etc. The sensitized layer may be dichromated gelatin, which, after exposure, is treated with a black dye to color the unexposed parts of the layer, or it may be of cellophane impregnated with a mixt. of sensitive diazo compds. and phenols, which, after exposure, is treated with an alk. bath or NH_3 vapor. The films or plates may be used in printing machines for reproducing embossed films.

Inscriptions on photographic film. I. G. FARBENIND. A.-G. Brit. 295,578, Aug. 13, 1927. Inscriptions on a film produced as described in Brit. 287,124 (C. A. 23, 349) by the use of a soln. of a dye in a slowly evapg. solvent are protected from injury during subsequent liquid treatment of the film (as in the polishing operation) by coating them with a colloid (such as benzyl cellulose dissolved in a mixt. of acetone and benzene), which is insol. in any of the solvents to be used in the film treatment and which does not affect the dye used for the inscription.

Cinematographic films. "SIRIUS" KLEUREN-FILM-MAATSCHAPPIJ. Fr. 646,693, Jan. 3, 1928. See Brit. 283,548 (C. A. 22, 4073).

Film for motion pictures in color. RODOLPHE BERTHON. U. S. 1,707,157, March 26. A backing has formed on its face microscopic refracting elements over which is placed a coating of transparent material such as bakelite, varnish, or gelatin; on the latter a coating of suitable sensitized emulsion is spread.

Dye solutions for printing inscriptions on photographic films. I. G. FARBENIND. A. G. Brit. 295,383, Aug. 12, 1927. Dye solns. such as a soln. or suspension of cerasin red or soot in glycol acetate are mixed with a soln. of a colloid such as cellulose acetate (for use on nitrocellulose film) insol. in the liquids which may be subsequently applied to the film after printing; finely dispersed pigments may also be used.

Photographic color prints. JOSEPH C. CARTER. U. S. 1,706,107, March 19. Positives are formed from color sepn. negatives on collodion emulsion plates; the positives are transformed into desired color positives, stripped from their supports and superposed to form color prints.

Optical features of screens for use in the lenticular film process of color photography. M. W. SKYMOUR (to Kodak, Ltd.). Brit. 295,995, Aug. 22, 1927.

Photographic developer. I. G. FARBENIND. A.-G. Brit. 295,939, Aug. 18, 1927. 2-Hydroxyethylamino-1-hydroxybenzene (suitably in the form of its sulfate) is used as a developer, together with Na_2SO_4 and K_2CO_3 . Cf. C. A. 23, 572.

Printing surfaces of celluloid or similar material. E. SAUER. Brit. 296,065, Aug. 24, 1927. A photographic gelatin relief is freed from all water by treatment with AmOAc , AmOH , or the like, and by the action of a blower or suction device. A celluloid surface is treated with a solvent and brought into contact with the treated gelatin relief.

6—INORGANIC CHEMISTRY

A. R. MIDDLETON

Valency. XII. FRANK L. GILBERT AND THOMAS M. LOWRY. *J. Chem. Soc.* 1928, 3179-89.—The α -base obtained from α -diethyltelluronium diiodide, m. 57° , is converted into a β -phase when its aq. soln. is evapd. to dryness at 100° , under 15-mm. pressure in a N atm. The corresponding α -tetraiodide m. 98° , β -diiodide m. 42° , β -dibromide m. -12° and β -dichloride m. -10° . With aq. NH_4OH , the α -diiodide gives an α -monoxoiodide, $[\text{O}(\text{TeEt}_2)_2]_2\text{I}_2$, m. $104-6^\circ$; the β -diiodide gives a triethyltelluronium iodide. The α -diiodide reacts with Ph_2Hg in CHCl_3 , and yields $(\text{TeEt}_2\text{I}_2)_2\text{HgPh}_2$, m. 94° , but it does not react with mercury-di-*p*-tolyl, nor does the latter react with α -dimethyltelluronium diiodide. The absorption spectra of the iodides in cyclohexane exhibit the twin maxima of the "iodoform band"; the bromides show a step-out. The β -base has a higher cond. than the α -base. Potentiometric titrations show that the β -base is stronger than the α -one during the first half of the neutralization, but is weaker during the second half, as is shown by the fact that the neutralization curves cross. ALBERT L. HENNE

Pure carbon monoxide for experimental purposes. J. G. THOMPSON. *Bur. Chemistry, Wash., D. C. Ind. Eng. Chem.* 21, 300-301 (1929).—An electrically heated app. is described (with diagram) for the continuous production of CO from HCOOH , using 85% P_2O_5 at 170° as dehydrating agent. The CO and steam from the reaction are sepd. by condensation and the CO is passed upward through a scrubbing tower contg. NaOH

soln. The dried gas is 99.9% pure. About 92% of the HCOOH is cracked to CO and H_2O . Only HCOOH and electricity are consumed and the H_2PO_4 baths can be used indefinitely. Two 10-l. Pyrex flasks served as generators, and the combined production was 200 cu ft. of CO in 7 hrs.

J. W. SHIPLEY

Preparation of chemically pure ammonium dichromate. YA. T. GERASIMOV. *Trans. Inst. Pure Chem. Reagents* (Moscow) 1927, No. 6, 22-6.—Attempts to prep. the pure substance by the double exchange between $\text{Na}_2\text{Cr}_2\text{O}_7$ and NH_4Cl in aq. soln. failed, the substance contg. too little NH_3 . NH_4 dichromate is slightly decompd. on boiling in aq. soln., a ppt. being formed which contains chromic oxide and chromic anhydride in varying ratios. The pure substance can be conveniently prepd. by neutralizing chromic anhydride with NH_3 in unsatd. soln. and evapg. at 50° .

G. B. KISTIAKOWSKY

A new method for the preparation of cuprous sulfate. J. G. F. DRUCE AND G. FOWLES. *Chem. News* 137, 385-6(1928).— Cu turnings are dropped into concd. H_2SO_4 at 200° , and when the reaction has stopped, the green soln. is decanted from any anhydrous CuSO_4 through an asbestos filter into a mixt. of 50% anhydrous alc. and 50% ether, or into MeOH . Cu_2SO_4 seps. in white crystals. It rapidly decomposes in moist air into Cu and CuSO_4 .

ALBERT L. HENNE

Preparation and conductivity of hydrogen fluoride. KARL FREDENHAGEN AND GUSTAV CADENBACH. *Chem. Inst., Greifswald. Z. anorg. allgem. Chem.* 178, 280-99 (1929).—If KHF_2 is slowly heated, the first third of its HF content is given off with gradually increasing temp., but the remainder is given off at a const. temp. (504°). H_2O in the bifluoride alters the course of the temp. curve, a const. value being reached only when nearly all the HF is driven off. The sp. cond. of the distillate obtained from moist KHF_2 is considerably greater than when dry material is used. Thus, the ninth distillate from dry KHF_2 gives for $\text{K} \cdot 10^{-6}$, 640 and from moist KHF_2 , 980. Still lower values are obtained for cond. if the HF is condensed in an intermediate vessel and redistd. from this, the cond. being measured only on fractions collected after the point of const. temp. in the heating of KHF_2 is attained. The lowest value obtained in this manner for the sp. cond. of HF is 14×10^{-6} , but the authors believe that this is still higher than the true value. Washing with KOH soln. followed by treatment with MgO paste or MgSO_4 soln. is recommended for HF burns.

H. STOERZ

Bromine chloride. S. BARRATT AND C. P. STEIN. Univ. College, London. *Proc. Roy. Soc. (London)* A122, 582-8(1929).—In spectrophotometric measurements of solns. of Br and Cl in CCl_4 the Br band in the visible spectrum was taken as a measure of the uncombined Br . Similar quant. observations for Cl in the ultra-violet were unsuccessful because of lapping of spectra. K of the mass action law varies least for a compd. BrCl . In equimol. mixts. combined Br is formed to approx. 50% of that present. A new absorption band, ascribed to BrCl , is also obtained in gaseous mixts. and aq. solns. The max. lies at 3700 A. U. In Et_2O and CHCl_3 the reaction takes place instantaneously at -78° . In CCl_4 diminution of color occurs for several seconds. There is no time lag in aq. solns. A lag in the gaseous state is suspected. The vol. change in mixing Cl and Br as gases is small or non-existent, which confirms the formula, BrCl .

FOSTER DEE SNELL

The hydroxides of ter- and quadrivalent elements. FRANZ ADICKES. *Z. anorg. Chem.* 41, 1333-6(1928).—A general article emphasizing the various degrees of hydration of SiO_2 and Al_2O_3 .

ALBERT L. HENNE

Compounds of alkali phosphates with hydrogen peroxide. HEINRICH MENZEL AND CURT GÄBLER. Tech. Hochschule, Dresden. *Z. anorg. allgem. Chem.* 177, 187-214(1928); cf. *C. A.* 22, 1923.—The solubilities of KH_2PO_4 , of $\text{Na}_2\text{HPO}_4 \cdot 12\text{H}_2\text{O}$ and of $\text{Na}_4\text{P}_2\text{O}_7 \cdot 10\text{H}_2\text{O}$ in H_2O were detd.

Temp.	KH_2PO_4	G. anhyd. salt in 1000 g. H_2O Na_2HPO_4	$\text{Na}_4\text{P}_2\text{O}_7$
0°	142.6	16.31	22.36
15°	201.7		
18°	215.5	63.67	51.47
25°	251.2	121.44	66.18

The solubilities of these salts in H_2O_2 solns. at 0° were also detd. The increase in their solubilities with addn. of H_2O_2 indicates union of H_2O_2 with the dissolved phosphates. By the evapn. of phosphate- H_2O_2 solns. at room temp. in a stream of dry air the compds. $\text{Na}_2\text{HPO}_4 \cdot 2\text{H}_2\text{O}_2$ (I), $\text{K}_2\text{HPO}_4 \cdot 2.5\text{H}_2\text{O}_2$ and $\text{KH}_2\text{PO}_4 \cdot \text{H}_2\text{O}_2$ or $\text{KH}_2\text{PO}_4 \cdot 1.25\text{H}_2\text{O}_2$ were obtained. The first 2 are rather stable; the third is not. By adding EtOH to a $\text{Na}_2\text{HPO}_4 \cdot 2\text{H}_2\text{O}_2$ soln. an oily lower layer having approx. the compn. $\text{Na}_2\text{HPO}_4 \cdot 2\text{H}_2\text{O}_2 \cdot 10\text{H}_2\text{O}$ was obtained. This could not be obtained in solid form; on evapn. in dry air it gave I.

I and $\text{Na}_4\text{P}_2\text{O}_7 \cdot 3\text{H}_2\text{O}$, when shaken with Et_2O , gave up H_2O_2 to the Et_2O ; warmed *in vacuo* they were scarcely attacked at 70° , but at 130° they were completely decompd. with removal of H_2O_2 into the anhyd. mother salts. In these compds. the H_2O_2 appears to be H_2O_2 of crystn.

LOUISE KELLEY

Behavior of hydrogen peroxide in aqueous alkali phosphate solutions. SVED HUSAIN. Tech. Hochschule, Dresden. *Z. anorg. allgem. Chem.* 177, 215-26(1928); cf. preceding abstr.—The salts used were the primary and secondary orthophosphates and the pyrophosphates of Na and K. Cryoscopic measurements were made on solns. of these salts contg. H_2O_2 and the distribution of H_2O_2 between solns. of these phosphates and AmOH was studied. The results showed that the capacity of the salts to bind H_2O_2 increases in this order: primary phosphate, secondary phosphate, pyrophosphate—and that within each salt type the K phosphate solns. add H_2O_2 more firmly than do solns. of the corresponding Na salts.

LOUISE KELLEY

Acid phosphates of thorium. J. D'ANS AND W. DAWIDL. *Z. anorg. allgem. Chem.* 178, 252-6(1929).—If $\text{Th}_3(\text{PO}_4)_4$ is stirred into H_3PO_4 contg. at least 40% P_2O_5 and the mixt. is allowed to stand, long crystals of the acid phosphate, $\text{Th}(\text{HPO}_4)_2 \cdot (\text{H}_2\text{PO}_4)_2 \cdot 2\text{H}_2\text{O}$ (I), gradually sep. Soly. detns. show that the transition from $\text{Th}_3(\text{PO}_4)_4$ to $\text{Th}(\text{HPO}_4)_2 \cdot \text{H}_2\text{O}$ occurs at about 20% P_2O_5 and 0.5% ThO_2 , while the transition to I occurs with about 30% P_2O_5 and 5% ThO_2 . If increasing quantities of H_2SO_4 are added to a soln. of $\text{Th}_3(\text{PO}_4)_4$ in H_3PO_4 , a very viscous soln. is obtained, from which, after standing several weeks at about 10° , a well-crystd. substance is obtained having the compn.:

$\text{Th} \begin{cases} (\text{H}_2\text{PO}_4)_2 \\ \text{SO}_4 \cdot 8\text{H}_2\text{O} \end{cases}$ It crystallizes in fine needles which are extremely sensitive to moisture.

Another acid phosphate occurs having the compn. $\text{Th} \begin{cases} \text{HPO}_4 \\ \text{SO}_4 \end{cases} \cdot 4\text{H}_2\text{O}$; it is likewise decompd. by H_2O . Soly. detns. show that this salt exists only below 44.5° . A phase diagram at 20° is shown, the points given being detd. only qualitatively. Analogous salts of Ce are indicated.

H. STORRTZ

The constitution of sodium plumbate. A. SIMON. *Z. anorg. allgem. Chem.* 177, 109-15(1928).—The decompn. of Na plumbate by heating was measured in a tensiometer. No evidence was found for a break in the isobar for 10-mm. pressure when 2 mols. of H_2O had been liberated. This leads to the conclusion that the formula for the salt is $\text{Na}_2\text{PbO}_3 \cdot 3\text{H}_2\text{O}$ rather than $\text{Na}_2[\text{Pb}(\text{OH})_6]$ (cf. Bellucci and Parravano, *Z. anorg. Chem.* 50, 111(1906), and Grube, *C. A.* 16, 3274). The anhydrous salt begins to decompose into Na_2O and PbO_2 at 750° . The latter liberates O_2 and passes over to PbO at this temp.

H. F. JOHNSTONE

Hydrates of calcium oxalate. W. F. JAKÓB AND E. LUCZAK. *Roczniki Chem.* 9, 41-8(1929).—The new hydrates of Ca oxalate, $\text{CaC}_2\text{O}_4 \cdot 2\frac{1}{2}\text{H}_2\text{O}$ and $\text{CaC}_2\text{O}_4 \cdot 3\text{H}_2\text{O}$, were prepd. by pptg. Ca oxalate in the presence of Na citrate under definite conditions and it has been found that they are unstable at ordinary temp., their transition points being far below 0° . The water of crystn. of both hydrates exhibits totally different properties. The trihydrate loses 2 mols. of H_2O at 40° , the hydrate, $\text{CaC}_2\text{O}_4 \cdot 2\frac{1}{2}\text{H}_2\text{O}$, however, gives off $\frac{1}{4}$ mol. of H_2O at 80° and one more mol. of H_2O at 100° . The soly. tables and photographs of hydrates are added.

JAROSLAV KUČERA

Reflex furnace reduction of oxides. R. SAXON. *Chem. Age* (London) 19, No. 484; *Monthly Met. Sect.* 19, 27(1928).—The furnace has a modified inlet for the reducing gases which gives them a higher temp. than in the customary devices. Thin crucibles are to be used, preferably made of calcined clay. The pores of the crucible should be closed by coating with shellac, resin or aluminum paint and roasting.

A. L. H.

The thermal decomposition of ammonia, with particular reference to the existence of active and inactive phases of ammonia. WM. A. STRINGFELLOW. *J. Chem. Soc.* 1929, 1-8.—The work of Baly and Duncan (cf. *C. A.* 16, 3273) on the catalytic decompn. of NH_3 on Pt filaments was repeated. S. finds that, contrary to the conclusions of B. and D., neither a variation in the rate of evapn. of NH_3 from the liquid phase nor drying of the NH_3 by CaO effects its rate of decompn. Conclusion: The effect observed by B. and D. was dependent upon factors not explicitly defined in their paper and did not result from the reported existence of 2 different types of gaseous NH_3 .

P. H. EMMETT

A new type of alum. W. R. C. CURJEL. *Nature* 123, 206(1929).—By allowing an aq. soln. contg. equimol. amts. of K_2BeF_6 and $\text{Al}_2(\text{SO}_4)_3$ to crystallize at room temp., cubic crystals having the compn. $\text{K}_2\text{BeF}_6 \cdot \text{Al}_2(\text{SO}_4)_3 \cdot 24\text{H}_2\text{O}$ were obtained. These normally crystallize as octahedra and readily form true overgrowths on the common alums.

A similar alum was obtained in which K_2ZnCl_4 is substituted for K_2BeF_4 . Rb_2BeF_4 crystals are isomorphous with K_2BeF_4 . Pseudo-hexagonal interpenetration triplets are frequently formed as thin flakes.

W. W. STIFLER

Equilibrium relations in the reduction, oxidation and carbonization of iron. VII. 8. Cobalt in a methane-hydrogen atmosphere. RUDOLF SCHENCK AND HEINRICH KLAS. Univ. Münster i. W. *Z. anorg. allgem. Chem.* 178, 146-56(1929); cf. *C. A.* 21, 3334, 3799.—Two reactions are possible, one in which Co acts purely as a contact substance, expressed by the equation $CH_4 \rightleftharpoons C + 2H_2$; and one in which the formation of carbide occurs: $nCo + CH_4 \rightleftharpoons Co_nC + 2H_2$. The system is investigated in the range 680-900°, and the compn. of the gas phase is varied between 0 and 100% for both H_2 and CH_4 , with small additions of CO and N_2 . The presence of Co-Co carbide mixed crystals follows from the gradual increase in % CH_4 . At first more dil. mixed crystals are formed which are in equil. with low CH_4 concns. With carbide increase in the solid soln., CH_4 concn. increases, reaching its max. when satn. with carbide is attained, and the occurrence of the pure carbide phase begins. This satn. concn. of CH_4 is about 18% at 680°, 15% at 700°, 14% at 720°, 10% at 760°, 7.5% at 800° and 3.7% at 900°. Co carbide is found to be more stable than Fe carbide. Complete decarbonization is not obtained with less than 97% H_2 in the gas phase. Phase diagrams are given which show the limits of the mixed crystal field.

H. STOERTZ

A ferric oxalate and a ferric oxalate perchlorate. R. WEINLAND AND KARL REIN. Univ. Würzburg. *Z. anorg. allgem. Chem.* 178, 219-24(1929).—Four g. of $Fe(NO_3)_3 \cdot 9H_2O$ and 2.6 g. of finely pulverized $H_2C_2O_4$ are dissolved in 30 g. concd. HNO_3 , the temp. is kept below 25° and the yellow soln. obtained is evapd. over H_2SO_4 . After a few hrs. a canary-yellow powder begins to sep., but complete sepn. requires 1 day. It is filtered out and washed with ice-cold H_2O . Analysis is in good agreement with the formula, $Fe_2(C_2O_4)_3 \cdot 5H_2O$, but its exact constitutional formula is not detd. Cond. measurements in H_2O soln. (0.004 *N*) at 18° give $\mu = 137$. This salt slowly dissolves in H_2O to form a yellow soln. acid to litmus. After standing a few hrs., H_2O solns. give Fe^{++} reactions, while after a few days an oxalate of Fe^{++} seps. $CaCl_2$ gives no ppt. at ordinary temps. even on long standing; with long heating a reddish yellow turbidity is formed. On addn. of $AcONa + CaCl_2$ to a soln. of the oxalate, a red ppt. is formed consisting of CaC_2O_4 and basic ferric acetate. To prep. ferric-oxalate-perchlorate, 5.4 g. of $FeCl_3 \cdot 6H_2O$ and 7.6 g. $H_2C_2O_4$ are dissolved in 120 g. of 50% $HClO_4$. The mixt. is heated at 100° until a bright green powder seps. It is filtered and washed with coned H_2O and dried over H_2SO_4 with alternate application of vacuum and dry air. The bright green crystals are very hygroscopic, analysis indicating the compn.: $Fe_2(C_2O_4)_3(C_2O_4H)_2(ClO_4)_2 \cdot 14H_2O$. Six mols. of H_2O are given up in a vacuum over H_2SO_4 . In spite of the high ClO_4^- content, this compd. is non-explosive, probably because of the high H_2O content. NH_4OH ppt. $Fe(OH)_3$ from its solns. but $CaCl_2$ gives no ppt. except when accompanied by $AcONa$. KCl gives a ppt. of $KClO_4$. Its constitutional formula is not detd.

H. STOERTZ

Mixed oxalate-fluoro-anions of tervalent chromium, iron, antimony and bismuth. R. WEINLAND AND WILHELM HÜBNER. Univ. Würzburg. *Z. anorg. allgem. Chem.* 178, 275-88(1929); cf. *C. A.* 15, 3256.—The C_2O_4 group shows great facility in forming one member of mixed anions of tervalent metals. Other acid constituents of the mixed anions are usually Cl , F , NO_3 or SO_4 . The possibility of numerous isomeric combinations of the members of the anions is indicated but not observed, although it is believed that the pyridine base may be divided between anion and cation. **Pyridine tri-oxalate trinitrate dichromate**, $[Cr_2(C_2O_4)_3(NO_3)_3(H_2O)_3]H_3Py_4$ is prepd. by dissolving 4 g. of $Cr(NO_3)_3 \cdot 9H_2O$ and 1.3 g. $H_2C_2O_4$ in 20 cc. of warm H_2O , and adding drop by drop with slight heating and stirring 2.4 g. of pyridine. The dark violet soln. is evapd. at 100° to about half its vol. and then evapd. over H_2SO_4 . Another method is intimately to mix CrO_3 and $H_2C_2O_4$ and add a little H_2O . To this mixt. is added $Cr(NO_3)_3 \cdot 9H_2O$, the mixt. warmed on a H_2O bath and pyridine added drop by drop. In either case the crystals which sep. are washed with acetone and dried over $CaCl_2$. They are dark violet plates, very sol. in H_2O and pyridine, insol. in Et_2O and acetone, and lose no H_2O in a vacuum over H_2SO_4 . In prepg. the quinoline compd. the base is combined with $H_2C_2O_4$ first and this added slowly to the nitrate soln. The crystals are rose violet, easily sol. in H_2O and quinoline, insol. in alc., Et_2O and acetone, and cannot be recrystd. from H_2O . The compn. is represented by $[Cr_2(C_2O_4)_3(NO_3)_3(H_2O)_3]H_3quin_7$. **Pyridine di-oxalate trifluorodichromate**, $[Cr_2(C_2O_4)_2F_3]H_3Py_3 \cdot 7H_2O$ is prepd. by grinding CrO_3 and $H_2C_2O_4$ in a mortar, covering with H_2O in a beaker and adding a soln. of pyridine hydrofluoride contg. an excess of pyridine. The mixt. is evapd. partly on a water bath and then allowed to stand in the air. The crystals are washed with alc. and dried over

CaCl_2 . They are green, easily sol. in H_2O with acid reaction, insol. in alc., Et_2O and acetone. The dry substance does not attack glass, nor does CaCl_2 give a ppt. from its soln. in H_2O . H_2O is not lost in a vacuum over H_2SO_4 . *Pyridine dioxalate pentafluorodichromate*, $[\text{Cr}_2(\text{C}_2\text{O}_4)_2\text{F}_5]\text{H}_3\text{Py}_2 \cdot 5\text{H}_2\text{O}$, is produced when pyridine is added slowly to a mixt. of $\text{CrF}_3 \cdot 3.5\text{H}_2\text{O}$ and $\text{H}_2\text{C}_2\text{O}_4$, followed by boiling for a few mins. and evapn. in the air. It is a bright green powder, similar in properties to trifluoride. *Pyridine oxalate difluorodiaoquerrate*, $[\text{Fe}(\text{C}_2\text{O}_4)\text{F}_2(\text{H}_2\text{O})_2]\text{H.Py}$, is prepd. by treatment of $\text{Fe}(\text{OH})_3$ with 40% HF, and adding to the soln. produced $\text{H}_2\text{C}_2\text{O}_4$, followed by pyridine. On standing in the air, fine white crystals sep., which are easily sol. in H_2O to a yellowish green soln. and are insol. in alc. and Et_2O . *Pyridine oxalate difluoroantimoniate*, $[\text{Sb}(\text{C}_2\text{O}_4)_2\text{F}_2]\text{H.Py}$, is prepd. by dissolving Sb_2O_3 in HF, followed by addition of a soln. of $\text{H}_2\text{C}_2\text{O}_4$ and then pyridine. It crystallizes in the form of large 4-sided colorless prisms, sol. in warm H_2O and dil. acids, insol. in alc. and Et_2O . On dissolving Sb_2O_3 in HCl followed by addition of $\text{H}_2\text{C}_2\text{O}_4$ and pyridine, a variety of products can be obtained depending upon the condition. If the excess acid is neutralized with pyridine, a white Cl-free salt is obtained. If more than double the calcd. quantity of HCl is used, an oxalate-free salt is obtained in the form of beautiful needles. The oxalate-chloro salt, $[\text{Sb}_4(\text{C}_2\text{O}_4)_3\text{Cl}_{12}]\text{H}_{10}\text{Py}_8$, is decomposed by H_2O with sepn. of SbOCl_3 , and is sol. in warm dil. HCl from which an oxalate-free salt seps. *Bismuth oxalate chloropyridine* salts are prepd. in a similar manner. $[\text{Bi}_3(\text{C}_2\text{O}_4)_4\text{Cl}_6]\text{H}_3\text{Py}_4 \cdot 10\text{H}_2\text{O}$ is colorless, cryst. (prismatic), sol. in dil. HCl and HNO_3 , decomposed by H_2O with sepn. of oxychloride.

H. STOERTZ

The degradation of quaternary ammonium salts. I. THOMAS S. STEVENS, ELTON M. CREIGHTON, ALEXANDER B. GORDON AND MALCOLM MACNICOL. *J. Chem. Soc.* 1928, 3193-7.—Quaternary phenacetylammmonium salts have been prepd. by refluxing the base with bromoacetophenone in C_6H_6 or EtOH , and isolating the resulting bromide or converting it into the iodide. The purpose of the work was to protect a secondary amino group with a more easily removable radical than benzyl. The following compds. were prepd.: phenacetylphenyldiethylammmonium iodide, m. 133° , phenacetyl- β -phenylethyldimethylammmonium bromide, m. 191° , diphenylacetyldimethylpiperazinium dibromide, m. $222-5^\circ$ (decompn.), hydrohydrastinine phenacetyl iodide, m. 190° . All the above compds. readily lose the phenacetyl radical on reduction in aq. soln. with Na amalgam. Phenylacetylbenzylidimethylammmonium bromide (I), m. $167-8^\circ$, gives on reduction with Zn and H_2SO_4 a crude base whose picrate m. $173-4^\circ$ and was identified with benzyltrimethylammmonium picrate, whose m. p. is given as $168-9^\circ$ in the literature. On reduction with Na amalgam, I gives a base, $\text{C}_{17}\text{H}_{19}\text{ON}$ (II), which is identical with the product obtained by the action of NaOH. This base is not obtained from I by the loss of a Me group, since its methobromide is not identical with I, but gives phenylstyrylketone when it is treated with hot alkali. By synthesis from ω -bromo- ω -benzylacetophenone and dimethylamine hydrochloride in the presence of NaOMe, it is shown to be ω -dimethylamino- ω -benzylacetophenone, m. $77-9^\circ$, whose picrate m. $147-9^\circ$ and methobromide + 0.5 EtOH m. $195-7^\circ$. ALBERT L. HENNE

Action of acetates and of formates on bismuth nitrate. M. O. KHARMANDAR'YAN. Kharkov Rural Econ. Inst. *J. Russ. Phys.-Chem. Soc.* 60, 1477-85(1928).—While it is known that by interaction of boiling concd solns. of $\text{NaC}_2\text{H}_3\text{O}_2$ and $\text{Bi}(\text{NO}_3)_3$, a white ppt. of easily hydrolyzable $\text{Bi}(\text{C}_2\text{H}_3\text{O}_2)_3$ is produced, the interaction of the 2 salts in lesser concns., as well as the equil. of the reactions at ordinary temp., have now been studied by K. The $\text{Bi}(\text{NO}_3)_3$ soln. used contained 0.014145 g.-mol. Bi_2O_3 and 0.037 g.-mol. N_2O_5 per l. of H_2O . By adding $\text{Bi}(\text{C}_2\text{H}_3\text{O}_2)_3$ solns., ppts. were obtained of hydrolysis products which consisted of basic salts, the compn. of which depended on the quantity of the acetate added. With small quantities of acetate $\text{Bi}_2\text{O}_3 \cdot \text{N}_2\text{O}_5$ was pptd. which, on further addn. of the acetate, became transformed into $2\text{Bi}_2\text{O}_3 \cdot \text{N}_2\text{O}_5$. With still greater concns. of the acetate there was, at first, a pptn. of $\text{Bi}_2\text{O}_3 \cdot \text{N}_2\text{O}_5$ which gradually hydrolyzed and turned to $\text{BiO} \cdot \text{C}_2\text{H}_3\text{O}_2$. The salt $2\text{Bi}_2\text{O}_3 \cdot \text{N}_2\text{O}_5$ differs from $\text{Bi}_2\text{O}_3 \cdot \text{N}_2\text{O}_5$ by not being sol. in an excess of the acetate with formation of $\text{BiO} \cdot \text{C}_2\text{H}_3\text{O}_2$. The quantity of $\text{Bi}_2\text{O}_3 \cdot \text{N}_2\text{O}_5$ increases with the increase of the quantity of the acetate, whereas the quantity of $\text{BiO} \cdot \text{C}_2\text{H}_3\text{O}_2$ decreases and tends to disappear in the presence of very great concns. of the acetate. The acetates of K, Ca, Ba, Co, Zn, Cu, etc., act like $\text{Na}(\text{C}_2\text{H}_3\text{O}_2)_3$, and so do the formates, but not the oxalates. A curve of the equil. of the reaction is given. The study of the kinetics of the reactions shows that, within 6 months, they were not yet ended, some of them still showing a slow increase of $\text{Bi}_2\text{O}_3 \cdot \text{N}_2\text{O}_5$ pptn., while in other cases a gradual resoln. of this was taking place, after reaching a definite max.

BERNARD NELSON

Compounds of oxygenated halogen acids with benzidine. A. E. KRETOV. *J.*

Russ. Phys.-Chem. Soc. 60, 1427-33(1928).—A group of new compds. was obtained by combining oxygenated halogen acids with benzidine. HClO , HBrO and HIO oxidize benzidine instead of combining with it. The most insol. and easily separable salt of this group was obtained with HIO_3 ; it is formed in the presence of either HCl or AcOH , and the hydrochloride as well as the acetate of benzidine can be used in concns. of 5-50 g. per l. If the hydrochloride is used, the salt, $\text{H} \cdot \text{O}_2\text{NH}_2\text{H}_2\text{C}_6\text{H}_4\text{NH}_2\text{HIO}_3$, is pptd. in the form of silvery leaves which sometimes contain a small quantity of free benzidine. With benzidine acetate this salt ppts. in the form of a cryst. powder. The ppt. does not decomp. on being kept at room temp., even under direct action of sunlight, although it darkens. Its sepn. from solns. of HIO_3 or of iodates being complete, and its soly. in water being insignificant (about 0.03 g. per l.), the reaction may be used for the detn. of HIO_3 or of iodates by a new method which does not involve I titrations. For the quant. sepn. of HIO_3 it is best to use benzidine acetate, and not the hydrochloride, although the latter gives a ppt. which filters faster; the reason is that in the presence of the slightest excess of free HCl benzidine iodate partly decomp. with I formation. The reagent needed for the quant. operation is prepd. by carefully triturating 50 g. benzidine with 80% AcOH , washing the pasty mass into a 1 l. volumetric flask and filling with H_2O to the mark. To ppt. 0.2 g. of KIO_3 , or of NaIO_3 dissolved in 50 cc. water, 10 cc. of the above reagent are used, which may be dild. with 10 times as much H_2O ; the mixt. is left standing 30 mins. and then filtered, the ppt. being washed, dried and detd. either by weighing, or by means of a Kjeldahl N analysis. This method of HIO_3 detn. is lengthy and less exact than the usual methods. The HBrO_3 salt of benzidine is more sol. than the HIO_3 deriv. It is prepd. by pptn. of a freshly prepd. 20-30% aq. soln. of HBrO_3 made by decomp. $\text{Ba}(\text{IO}_3)_2$ with diluted H_2SO_4 and evapg. *in vacuo* with a satd. soln. of benzidine in EtOH . HClO_3 , which is prepd. in the same manner as HBrO_3 , gives with benzidine in alc. soln. 2 combinations: when benzidine is in excess, $\text{C}_6\text{H}_4\text{NH}_2(\text{C}_6\text{H}_4)_2\text{NH}_2\text{HClO}_4$ is obtained, whereas $\text{HClO}_2\text{NH}_2(\text{C}_6\text{H}_4)_2\text{NH}_2\text{HClO}_4$ is formed in the presence of an excess of the acid; the first of these could not be obtained in a perfectly pure state, in spite of having been washed with EtOH . Benzidine salts of HBrO and HClO are, like that of HIO_3 , very stable at room temp.; on prolonged keeping their coloration changes, but not their compn. On being quickly heated they detonate somewhat, particularly in the presence of H_2SO_4 ; a real explosion occurs with the HClO_3 salt in the presence of a very insignificant quantity of HNO_3 . These salts can be exactly titrated with phenolphthalein as indicator. A soln. of 0.02 g. HClO_4 in 10 cc. H_2O gave with a dil. soln. of benzidine- HCl (4 g. per l.) a yellowish green coloration which, on boiling, turned to cobalt-pink. The reaction is more distinct with stronger solns. However, the derivs. of HClO_4 and benzidine are obtained in alc., not in aq. soln. When an alc. soln. of benzidine is gradually added to an alc. soln. of HClO_4 , sp. gr. 1.2, the blue ppt. at first obtained becomes gray when benzidine is in excess. The dark blue powder obtained decomp. on being heated to 100° . Its compn. is $\text{HClO}_2\text{NH}_2\text{C}_6\text{H}_4\text{C}_6\text{H}_4\text{NH}_2$. If an excess of HClO_4 is added to an alc. soln. of benzidine, a white ppt. of a different compn. is formed; the latter cannot be titrated exactly in the presence of phenolphthalein.

Complex chemical behavior of lithium. I. The systems lithium halide, mono-, di- and tri-methylamine. A. SIMON AND R. GLAUNER. *Stuttgart Tech. Hochschule Z. anorg. allgem. Chem.* 178, 177-201(1929).—Li halides react with the 3 methylamines to form addn. products as follows: LiCl forms addn. compds. with 1, 2, 3 and 4 mols. of CH_3NH_2 , decomp. at 16° , 0° , -19° and -47° , resp.; with 1, 2 and 3 mols. of $(\text{CH}_3)_2\text{NH}$, decomp. at 3° , -15° and -36° , resp.; and with 1 and 2 mols. of $(\text{CH}_3)_3\text{N}$, decomp. at -15° and -41° , resp. LiBr forms addn. compds. with 1, 2, 3, 4 and 5 mols. of CH_3NH_2 , decomp. at 63° , 35° , 28° , -32° and -57° , resp.; with $1/4$, 1, 2, 3, 4 and 5 mols. of $(\text{CH}_3)_2\text{NH}$ decomp. at 59° , 44° , 30° , -18° , -30° and -61° , resp.; and with 1 and 2 mols. of $(\text{CH}_3)_3\text{N}$, decomp. at 23° and -15° , resp. With LiI these addn. products are not so sharply defined, adjacent compds. having a strong tendency to form mixed crystals with one another. This obscures the transition from one compd. to the next containing one less mol. of amine. With LiI , addn. compds. with 3.5, 3, 2.5, 2 and 1 mols. of CH_3NH_2 are pretty well established, and compds. with $1/4$, $1/2$, and 1.5 mols. are also indicated, if not very definitely. With 1, 2 and 3 mols. of the amine the decompn. temp. is 100° , 40° and -3° , resp. LiI forms compds. with $1/4$, 1, 1.5, 2, 3 and 5 mols. of $(\text{CH}_3)_2\text{NH}$, the 1, 2, 3 and 5 mol. compds., decomp. at 90° , 20° , 5° and -72° . LiI definitely forms compds. with 1.5 and 2 mols. of $(\text{CH}_3)_3\text{N}$, decomp. at 30° and -16° , resp., while only indications are given of similar compds. with $1/4$ and 1 mol. of $(\text{CH}_3)_3\text{N}$. All the LiCl compds. are white and very voluminous, but as the mol. wt. increases, they become less voluminous and more cryst.; the LiI compds. are all quite cryst. The structure of these compds. is

discussed in detail, and thermochem. data give the following values for the "conventional chem. const." C . For CH_3NH_2 , $C = 3.35$; for $(\text{CH}_3)_2\text{NH}$, $C = 3.6$; for $(\text{CH}_3)_3\text{N}$, $C = 3.1$. The heat of reaction Q in the formation of addn. products between Li halides and the amines is given as follows: For LiCl with 1 mol. of mono-, di- and tri-amine, $Q = 12.2$, 8.72 and 6.9 cal., resp.; for LiBr these values are 14.49, 9.87 and 7.75 cal.; and for LiI 16.33, 11.5 and 9.5 cal.

H. STOERTZ

A study of molybdates, nitrophosphomolybdates, tungstates and phosphotungstates and their reactions. TEÓFILO GASPÁR Y ÁRNAL. *Anales soc. españ. fís. quim.* 26, 435-45(1928).—Reactions of these compds. with Li, Na, NH_4 , K, Cu^{++} , Rb, Ag, Cs, Be, Mg, Ca, Zn, Sr, Cd, Ba, Hg^+ , Hg^{++} , Al, Ti^+ , Pb^{++} , Th, Bi, UO^{++} , Mn^{++} , Fe^{+++} , Ni^{++} and Co^{++} , useful in analysis, are tabulated.

E. M. SYMMES

Thorium formates. HANS REIHLEN AND MAX DEBUS. Karlsruhe Techn. Hochschule. *Z. anorg. allgem. Chem.* 178, 157-76(1929).—If alkali salts react with Th formate, well-crystd. compds. are formed which contain 3 Th atoms, 6 HCOO residues and 1 mineral residue, as well as 5 OH groups. From these, many complex Th compds. can be built up. If 8 g. KCNS react with a soln. of 10 g. of $[\text{Th}_3(\text{HCOO})_6(\text{OH})_5] \cdot 10\text{H}_2\text{O}$ (I), the result is *potassium trithorium hexaformate oxy-tetrahydroxythiocyanate*, $\text{K}[\text{SCN}(\text{OH})_4\text{O}(\text{HCOO})_6\text{Th}_3] \cdot 7\text{H}_2\text{O}$ (II). The crystals are sol. and lose 7 mols. of H_2O at 18° and 1-2 mm. pressure. On heating at 61° and 1-2 mm., 8 mols. of H_2O are given off to form the trioxy compd., $[\text{Th}_3(\text{HCOO})_6\text{O}(\text{SCN})]\text{K}$. To a soln. of 86.5 g. of KSCN in H_2O at 35° , an excess of $[\text{Th}_3(\text{HCOO})_6\text{O}(\text{OH})_5]$ (III) is added, the soln. is filtered and held at 0° for 8 days, after which 9 g. more of III are added at room temp. On cooling to 0° , *dipotassium trithorium hexaformate dioxidyhydroxydithiocyanate*, $\text{K}_2[(\text{SCN})_2(\text{OH})_5\text{O}_2(\text{HCOO})_6\text{Th}_3]$, is formed; it is mixed with $\frac{3}{2}$ mols. of II. If III is added to a soln. of NaNO_3 , the resultant product is *sodium trithorium hexaformate tetrahydroxyoxynitrate*, $\text{Na}[\text{Th}_3(\text{HCOO})_6\text{O}(\text{OH})_4\text{NO}_3] \cdot 10.5\text{H}_2\text{O}$ (IV). If NaNO_3 reacts with $[\text{Th}_3(\text{HCOO})_{10}(\text{OH})_5] \cdot 7\text{H}_2\text{O}$ (V), a mixed compd. of 1 mol. of IV and 1 mol. of $[\text{NO}_3(\text{OH})_4(\text{HCOO})_6\text{Th}_3]$ is formed. The analogous K compd. is formed in a similar manner and crystallizes with 30 mols. of H_2O . NaClO_4 reacts with V to produce *sodium trithorium hexaformate tetrahydroxyoxychlorate*, $\text{Na}[\text{ClO}_4(\text{OH})_4\text{O}(\text{HCOO})_6\text{Th}_3] \cdot 13\text{H}_2\text{O}$ (VI), easily sol. in H_2O and concd. NaClO_3 soln. The K compd. can only be prepd. mixed with 2 mols. of III. The perchlorate of the Na compd. (VII) is prepd. by reaction of NaClO_4 with I. This salt is very hygroscopic when dried. If $\text{Th}(\text{OH})_4$ is dissolved in H_2O and the soln. heated with 40% HCOOH the *dodeca-trithorium formate* $[\text{Th}_3(\text{HCOO})_{12}] \cdot 9\text{H}_2\text{O}$ (VIII) is produced. If this is treated at 100° with 100% HCOOH , it loses H_2O and forms $[\text{Th}_3(\text{HCOO})_{12}] \cdot 3.5\text{H}_2\text{O}$. If neutral Th formate is dissolved in cold H_2O and heated at 100° , a compd. crystallizes out which must be filtered hot and washed with boiling H_2O ; it is probably $[\text{Th}_3(\text{HCOO})_6(\text{OH})_6] \cdot 4\text{H}_2\text{O}$ (IX). The mol. cond. of a g.-mol. dissolved in 64 l. of H_2O is given for some of these compds. as follows: for IV, 68; for II, 63; for VI, 78 in 256 l.; for VII, 56; for VIII, 52.5, for IX, 14. The structure of these compds. is discussed in detail.

H. STOERTZ

7—ANALYTICAL CHEMISTRY

W. T. HALL

Progress of electroanalysis. A. SCHLEICHER. Tech. Hochschule Aachen. *Z. angew. Chem.* 42, 146-8(1929).—A discussion of the progress made since the World War.

W. T. H.

Some comparative colorimetric determinations. R. WASMUTH. Tech. Hochschule Aachen. *Z. angew. Chem.* 42, 133-4(1929).—Comparative studies with the immersion colorimeter showed that 3.6-4.9 mg. of Fe could be detd. by the KCNS reaction with an accuracy of 10% of the actual Fe content and Mn can be detd. by the PbO_2 - HNO_3 oxidation to MnO_4^- within 5% of the actual Mn content. Results with the persulfate oxidation method were not so good as the shade developed was often quite different from that of pure MnO_4^- .

W. T. H.

Organic microanalysis. W. GARNER. *Ind. Chemist* 5, 58-61(1929).—A discussion of typical methods to use for the identification of an unknown org. substance.

W. T. H.

Use of ultra-violet light in volumetric analysis. J. EISENBRAND. *Pharm. Ztg.* 74, 249-52(1929).—The importance of fluorescence in connection with p_H is emphasized. It is shown that indicator characteristics (not only change of fluorescence with p_H , but also sharper transition point) of fluorescing substances are not at all uncommon, being

frequently met with in material of very simple character. Aside from the well-known indicators, quinine and umbelliferone, the naphthols (particularly β -naphthol) are recommended as acids of the simplest constitution and indicators possessing equal fluorescent intensity. The many-sided applicability of quinine, inadequately explained in previous publications, is now shown by a series of examples. A provisional scale of fluorescing indicators is given. The possibility of detg. the dissociation constants of fluorescent substances by means of the fluorescent transition point is pointed out. W. O. E.

Immersion colorimetry. R. WASMUHT. *Chem. Fabrik* 1929, 37-8.—This method has been developed for the estn. of small quantities of metal oxides in Fe and steel residues. A modified Dubosq instrument is used adopting the Bürker principle to obtain optical symmetry it is now called the "Universal Colorimeter." The instrument can be used for microcolorimetry. S. L. B. ETHERTON

Systematic study of indicators. XV. Phenolphthalein and some of its homologs. A. THIEL AND L. JUNGFER. Univ. Marburg. *Z. anorg. allgem. Chem.* 178, 49-72(1929).—Previous work has shown that phenolphthalein and similar compds. contg. substituent groups can form colored quinoidal anions and colorless lactoidal anions. It seems more and more probable that the bleaching effect of the OH ion is due to the formation of such lactoidal secondary anions. To investigate this further the following phthaleins were prepd. and studied: phenol-*m*-cresolphthalein or 2'-methylphenolphthalein; *m*-cresolphthalein or 2',2''-dimethylphenolphthalein; dimethylfluoran; *o*-cresolphthalein or 3',3''-dimethylphenolphthalein; *p*-xylenolphthalein or 2',5',2'',5''-tetramethylphenolphthalein. Extinction measurements were made in the visible spectra by means of the spectrophotometer. The values obtained agreed with those obtained by other investigators and with previous measurements of T. and J. The intervals of color change and of bleaching were measured in terms of $pH^{1/2}$. The *p*-xylenolphthalein proved very stable to OH⁻. It was shown long ago that the decoloration by strong alkali is due to the formation of a tertiary salt of phenolphthalein (carbinolcarbonate). It is probable that the OH ion attacks the lactoidal or colorless form of the secondary anion but it has been doubtful whether H₂O first is taken up with the formation of carbinolcarbonic acid and then by dissocn. the tertiary anion results or whether the OH ion is taken up directly, breaking the lactone bridge. The present work seems to confirm the latter view. It is interesting also to note that rise of temp. favors the formation of the colored anion during the range of color change. W. T. H.

Improved directions for preparing a universal indicator which gives the colors of the spectrum over a pH range of 2-12. H. W. VAN URK. *Pharm. Weekblad* 66, 157-62(1929); cf. *C. A.* 23, 752.—Dissolve 70 mg. tropeolin OO, 100 mg. methyl orange, 80 mg. methyl red, 400 mg. bromothymol blue, 500 mg. naphtholphthalein, 400 mg. cresolphthalein, 500 mg. phenolphthalein and 150 mg. alizarin yellow R in 100 cc. dil. EtOH. One drop of this soln. dild. to 10 cc. gives the following colors—at pH 2 orange-red, 3 red-orange, 4 orange, 5 yellow-orange, 6 orange-yellow, 6.5 yellow, 6 green-yellow, 8 green, 8.5 blue-green, 9 green-blue, 9.5 violet-blue to blue-violet, 10 violet, 11 violet to violet-red, 12 violet-red. This indicator covers a wider pH range and gives sharper color changes than the one previously recommended (*C. A.* 23, 752). The use of a color chart is helpful but not essential. A table gives color comparisons of the author's 2 indicators and the indicators proposed by Kolthoff. A. W. DOX

Titration curves of some liquids titrated with phenolphthalein. VLADIMIR MAYER. Exptl. Inst. Cz. Sugar Ind., Prague. *Listy Cukrovar.* 47, 211-4(1928).—Ten cc. of alk. solns. such as are obtained in sugar control work were titrated with 0.1 N HCl. phenolphthalein being used as indicator. Then, when the color had just disappeared, the pH of the colorless soln. was detd. colorimetrically with bromothymol blue and bromocresol purple. Finally, a drop more of acid was added and the pH again detd. In the presence of aspartic acid, the color of phenolphthalein disappears when the $pH = 7.4$. In a soln. contg. saccharose and lime, the phenolphthalein color disappears at $pH = 7.0$. Fresh diffusion liquor gives the phenolphthalein end point at $pH = 7.7$ but chilled liquors obtained at the end of the season give a phenolphthalein end point at $pH = 8.0$. 8.2. A mixt. of invert sugar, lime and aspartic acid or pectins shows a pronounced effect of hydrolysis which is not shown by the decompn. products of invert sugar alone. FRANK MARESH

New method for making up molybdic acid solution for use in phosphoric acid determinations. J. F. BREAZEALE. *Chemist-Analyst* 18, No. 2, 4(1929).—The order of adding the chemicals is changed somewhat. W. T. H.

Notes on the determination of bismuth. GEORGE J. HOUGH. *Chemist Analyst* 18, No. 2, 3-4(1929).—Treat 0.5 g. of ore with HNO₃ and evap. nearly to dryness. Add 2-3 cc. more of HNO₃ to prevent hydrolysis, warm and filter, keeping the total vol.

to about 50 cc. Neutralize with NH_4OH to faint opalescence, add 1 cc. of 6 N HCl and 200 cc. of cold water. Stir well and allow to stand several hrs. in the cold or 1 hr. on the steam bath. Decant through a filter and wash the BiOCl ppt. by decantation with hot water. To the ppt. in the beaker, add 5 g. of NH_4Cl , 25 cc. of hot water and 1 cc. of 7.5 N H_2SO_4 . Pour through the filter. Wash the beaker with 0.75 g. of NH_4Cl , hot water and a few drops of H_2SO_4 . Wash the filter thoroughly, bringing the total vol. of soln. to 150–200 cc. Insert a small square of Al foil and boil gently for 30 mins. to ppt. the Bi. Remove the Al, allow the ppt. to settle and decant off the liquid. Wash the Bi twice by decantation with hot water. Dissolve the Bi in 10–15 cc. of satd. FeCl_3 soln., gently heating. Add 200 cc. of cold water and 5 cc. of sirupy H_3PO_4 ; titrate the reduced Fe with KMnO_4 . W. T. H.

Detection and estimation of calcium, barium and strontium. W. SINGLETON. *Ind. Chemist* 5, 71–3(1929).—A review of well-known methods. W. T. H.

Potentiometric titration of gallium. SUNAO ATO. *Sci. Papers Inst. Phys.-Chem. Research (Tokyo)* 10, 1–5(1929).— GaCl_3 can be titrated potentiometrically against $\text{K}_4\text{Fe}(\text{CN})_6$. When the HCl concn. lies within 0.005–0.0025, $\text{Ga}_3(\text{Fe}(\text{CN})_6)_3$ is formed; otherwise the ppt. does not correspond to this formula. It is recommended, therefore, to titrate with this acidity at 40–50°. W. T. H.

Lead in white arsenic. H. W. JONES. *Chemist-Analyst* 18, No. 2, 11(1929).—Boil 20 g. of As_2O_3 with 500 cc. of HCl until only 100 cc. remains. Add 500 cc. more of acid and boil down to 50 cc. This will serve to volatilize practically all of the As as AsCl_3 . Add 250 cc. of water, neutralize to litmus with NaOH , add 5 cc. of 10% Na_2S and heat to boiling. Filter off the PbS , dissolve in HNO_3 and ppt. as PbSO_4 in the usual way. Dissolve the ppt. in hot AcONH_4 , ppt. PbCrO_4 by adding $\text{K}_2\text{Cr}_2\text{O}_7$ and weigh after drying. W. T. H.

Determination of aluminum in steel. A. T. KITTREDGE. *Analyst* 54, 141–4(1929).—The usual method for detg. Al in steel is unreliable. Take 10 g. of steel and dissolve in 100 cc. of concd. HCl . Oxidize with a min. quantity of HNO_3 , evap. to small vol. and carry out the Rothe ether sepn. to remove the greater part of the Fe. Evap. with H_2SO_4 and electrolyze with a cathode of Hg to remove the remainder of the Fe and other interfering ions. After the electrolysis, remove traces of Hg with H_2S , conc. by evapn., add 5 g. of NH_4Cl and ppt. the Al as $\text{Al}(\text{OH})_3$ by the addition of concd. NH_4OH , using methyl red as indicator. Ignite carefully and weigh. Run a blank test on all the reagents. If the wt. of the ppt. is less than 5 mg. it is hardly worth while to correct for P_2O_5 , Fe_2O_3 , Mn_2O_3 and Cr_2O_3 . In this case the Al should be detd. colorimetrically with aurin-tricarboxylic acid as described by Lundell and Knowles. In either case, fuse with $\text{K}_2\text{S}_2\text{O}_7$ and extract with water. If V or Ti is present, det. the quantity colorimetrically by treatment with H_2O_2 . Det. Fe by nearly neutralizing with NH_4OH , adding H_2SO_4 , boiling off excess and titrating with KMnO_4 . Det. Mn colorimetrically by the persulfate and AgNO_3 method, allowing for the KMnO_4 added in the foregoing titration. Det. Cr colorimetrically. Det. P_2O_5 by adding a nitric acid soln. of 0.1 g. of electrolytic Fe, pptg. with NH_4OH and from the HNO_3 soln. of this ppt. det. P by the usual molybdate pptn. followed by alkalimetric titration. In the analysis of 5 steels, from 0.01 to 0.22% of Al was found. The uncorrected values ranged from 0.02 to 0.25%. W. T. H.

Rapid method for determining vanadium in ferro-vanadium. JAMES SILBERSTEIN. *Chemist-Analyst* 18, No. 2, 11(1929).—The method depends upon the fact that III reduces V only to the valence of 4 when H_3PO_4 is present. Fuse 1 g. of material in a Ni crucible with 10 g. NaOH for 20 mins. Leach with water and filter into a 500-cc. measuring flask. Take 50 cc., add 75 cc. of H_3PO_4 (d. 1.7) cool and add KI. After 5 mins. titrate with 0.05 N $\text{Na}_2\text{S}_2\text{O}_8$. W. T. H.

Determination of oxygen in steel and iron. ST. REINER. *Z. angew. Chem.* 42, 159–60(1929). OSKAR MEYER. *Ibid.*—Meyer (*C. A.* 23, 1078) has described methods now being used for detg. O in Fe and steel but neglected to mention the improvement in Oberhoffer's app. which was suggested by R. To this M. replies that the method referred to is out of date. W. T. H.

Iodometric estimation of iron. EGBERTON C. GREY. *J. Chem. Soc.* 1929, 35–9.—The iodometric method for detg. Fe is accurate down to 0.05 mg. of Fe. A considerable excess of KI and of HCl should be used for the reduction. The reduction is complete in 3 mins. if the soln. is N in HCl . Sometimes the blue color returns after the end point is reached with $\text{Na}_2\text{S}_2\text{O}_3$ and in many cases this is due to the presence of a small quantity of Cu. To det. Fe in plants, therefore, it is advisable to leach the ash with concd. HCl and ppt. Fe with NH_4OH . Dissolve the $\text{Fe}(\text{OH})_3$ ppt. in HCl and in the final soln. have at least 0.4 cc. of HCl in 10 cc. of soln. To this add 0.33 g. of KI dissolved in not over

5 cc. of water. After 3 mins. dil. somewhat, add NaOAc if desired, and titrate with $\text{Na}_2\text{S}_2\text{O}_3$. W. T. H.

Quantitative electrolytic reductions. I. Reduction of tervalent iron to the bivalent state. EDGAR NIETZ. Univ. Leipzig. *J. prakt. Chem.* 121, 1-26(1929).—The electrolytic reductions took place in an 80-cc. beaker, the diam. of which was about 5 mm. wider than that of the Pt cathode used. In the middle of the beaker was placed an anode cell of clay or of collodium, the upper edge of the cell being above the level of the liquid in the beaker. From 40 to 50 cc. of dil. H_2SO_4 was placed in the cell and it was placed in the beaker after elec. connections had been made and the current turned on. A current of 1 amp. served to reduce 0.1394 g. of Fe^{+++} in about 40 mins. The max. yield of Fe^{++} under the conditions of the expt. was 99.7% of the total Fe present. There was a tendency for a little of the Fe soln. to diffuse into the anode compartment and for Fe to be absorbed by the walls of the inner cell. Moreover, probably a little oxidizer, perhaps $\text{S}_2\text{O}_8^{--}$, diffuses into the cathode compartment and serves to oxidize some of the Fe. **II. Reduction of nitric acid.** *Ibid.* 27-55.—The expts. were performed with quantities of KNO_3 varying from 0.1 to 0.7 g. The KNO_3 was assumed to be pure, the results obtained by the Pelouze-Fresenius method of analysis varying $\pm 0.3\%$. Most of the expts. took place with a Pt-gauze cathode covered with a spongy deposit of Cu and a spiral anode making about 300 r. p. m. The e. m. f. between the electrodes was 5.5 v. and the current did not exceed 2 amps. All the results were 0.3-0.5% too low. The following errors account for the low results: (1) a little N escapes as N_2 and it was not possible to prevent this error entirely. (2) Unless the soln. is neutralized at the end of the electrolysis there is danger of some Cu being dissolved by the H_2SO_4 (the electrolyte contained 0.3-20 cc. of 0.4 N H_2SO_4). If the soln. was neutralized before removing the cathode and washing it, this error became insignificant. (3) The reduction of the nitrate yields NH_4^+ chiefly, but besides a little N_2 some NH_4OH salt is often formed, particularly when the cathode surface is not sufficiently rough and when the current lines are not symmetrical so that the cathode c. d. is not uniform and when the cathode is too near the sides of the beaker. Potential measurements showed that the reduction of the nitrate caused a marked increase of the depolarization of the spongy Cu electrode, that the depolarizing effect of NO_3^- is related to a min. concn. which is lower for spongy Cu than for bright Cu; that abundant hydroxylamine formation takes place only when the cathode potential exceeds a certain neg. value; and that a marked H polarization takes place with spongy Cu cathodes after the reduction of the NO_3^- is complete. Conditions are stated under which these phenomena take place and also those under which no reduction of NO_3^- is accomplished. W. T. H.

Rapid method for determining tin in lead base alloys containing antimony. T. B. DIANA. *Chemist-Analyst* 18, No. 2, 8(1929).—To 0.5 g. of filings add 0.3 g. of pure Sn to make the Sn content at least 3 times that of the Sb. Heat with 15 cc. of 7.5 N HNO_3 until the metal is all attacked. Boil off excess acid and add 40 cc. of hot water, while stirring. Filter and wash alternately for 10 times with hot water and 1.5 N HNO_3 . Ignite carefully and weigh the SnO_2 and Sb_2O_3 . Subtract the wt. of Sb_2O_3 corresponding to a value obtained in another sample by titration and the weight of SnO_2 corresponding to the added Sn. Some Pb is usually present but can be neglected in routine work. W. T. H.

Rapid method for determining tin in tin plate. W. A. MASEL. *Chem.-Ztr.* 53, 108(1929).—The method depends upon the fact that the Sn coating can be removed very quickly by the action of a soln. of Cl_2 in SnCl_4 without dissolving the underlying Fe. Make a fine opening in the bottom of a stout test tube and provide an Fe handle for the tube. Weigh out into this test tube any desired amt. of finely cut, washed and dried metal and push the tube down into a soln. of Cl_2 in SnCl_4 contained in a cylindrical vessel. When no more bubbles of gas are evolved and no more bright places remain visible on the metal surface, the reaction is almost over. After about 5 mins. longer, allow most of the SnCl_4 to drain off and then quickly plunge the test tube into a vessel containing benzene. Wash thoroughly with benzene and finally with a little ether, dry and weigh. The loss in wt. can be called Sn. The result is usually 0.1% of the original wt. too low. To prep. the reagent in quantity sufficient for 25-50 analyses, take 500 g. of SnCl_4 and sat. with Cl_2 . It will absorb about 30 g. of Cl_2 . W. T. H.

Microanalysis for the determination of iodine in organic materials. J. F. REITH. Centraal Lab. Volksgezondheid, Utrecht. *Chem. Weekblad* 26, 20-7(1929).—To destroy org. matter in which I is to be detd. heat 20 g. in an O_2 stream, absorb the gases in alkali and analyze the ash separately. B. J. C. VAN DER HOEVEN.

Critical studies of gasometric methods for determining nitrous oxide. HEINRICH MENZEL AND WALTER KRETZSCHMAR. Tech. Hochschule, Dresden. *Z. angew. Chem.*

42, 148-56(1929).—With 99.4% pure N_2O prepd. from NH_4NO_3 , the best-known methods of analysis lead to the following conclusions: Winkler's method, using a modified explosion pipet here described, gives results within 0.2 cc. of the truth in the analysis of gases contg. not more than 10% of N_2O . If more than this is present, the gas attacks Hg and it is impossible to read the vol. accurately. The explosion with detonating gas as recommended by Heymann cannot be used when more than 5% of N_2O is present; with higher content nitrous gases appear. Bunsen's method of reducing with H_2 under the conditions recommended by him and by Hempel gives good results with N_2O , varying from 0.4 to 100%, whether the reduction is made to take place in an explosion pipet or in a capillary contg. Pt. Thermic decompn. of N_2O and reduction by H_2 in a Dietz Pt capillary is absolutely unreliable. O_2 can be detd. in gases contg. N_2O by means of a P-pipet with Hg as confining liquid and only an extremely small quantity of water. After the removal of O_2 , the N_2O can be detd. by one of the methods recommended above as soon as the small vol. of H_2O is in equil. with the N_2O . W. T. H.

Electrolytic method for the analysis of nitrates. MARK RABINOVITCH AND A. S. FOKIN. *Z. Elektrochem.* 35, 18-20(1929).—The method depends upon the reduction of a sol. nitrate to NH_3 by the action of freshly prepd. Hg-Na in the presence of a catalyzer such as metallic W, $VOSO_4$ or H_2PtCl_6 . The Hg is prepd. by electrolytic reduction of NaOH using a current of about 4 amp. The Na-Hg does not react readily with dil. NaOH soln. and scarcely at all with concd. NaOH. The electrolyzing vessel is a beaker contg. a layer of Hg, 2-2.5 cm. deep. Into this Hg is placed a cylindrical vessel open at the bottom, arranged so that the shaft of a motor-driven stirrer can be inserted at the center through glass tubing sealed in the vessel. Any gas formed within the cylinder can escape through only one opening and here also the substance to be analyzed is introduced. Outside of this cylindrical vessel, the beaker contains a 45% soln. of NaOH; inside the cylinder is a 20% NaOH soln. These 2 solns. are sepd. by the Hg seal. A Pt electrode is placed in the outer compartment to serve as anode and the Hg at the bottom of the beaker is made the cathode. By electrolysis, Na-Hg is formed at the bottom of the beaker and this with the aid of the catalyst reacts with about 0.2 g. of dissolved alkali nitrate present in the inner compartment. NH_3 escapes from the cell together with H_2 and is made to pass into a measured vol. of standard H_2SO_4 . Finally, the contents of the beaker are heated to boiling to distil off the last traces of NH_3 . Then the excess acid is titrated, with methyl orange as indicator. The results obtained with pure KNO_3 agreed closely but showed only 97% of the theoretical value but comparative results obtained with Devada's alloy averaged somewhat lower. W. T. H.

A new method for the colorimetric determination of nitrates in soils and in waters. LUIGI UMBERTO DE NARDO. *Compt. rend.* 188, 563-5(1929).—Pyrogallolsulfonic acid is an excellent reagent for the nitrate ion. Take 5 g. of pyrogallol and heat for a few mins. with 10 cc. of concd. H_2SO_4 at 80-90°. Cool and add water to make 200 cc. A small quantity of $NaHSO_4$ may be added as preservative. This reagent is very sensitive to the nitrate. As little as 0.0005 mg. gives a pink color. With larger quantities a reddish brown or an olive-green shade is obtained. Take 10 g. of soil, agitate for an hr. with 200 cc. of water, filter and take 80 cc. of the filtrate. Add 1-3 cc. of satd. $Ba(OH)_2$ soln., boil, let settle, add 0.5-1 cc. of 50% Pb subacetate soln. and after 2-3 mins. ppt. the excess Ba and Pb by adding 5 cc. of satd. Na_2SO_4 soln. Dil. to 100 cc., mix well and filter. Take 10 cc. in a 50-cc. porcelain dish and if nitrites are presented decomp. with urea and 1 cc. of H_2SO_4 . After 10 mins., add 0.5 cc. of the reagent and mix with 20 cc. of concd. H_2SO_4 . Compare the color with standards. If the test is too strong, use pyrogallol as reagent instead of the sulfonic acid. W. T. H.

Method for determining small quantities of silicic acid in orthophosphoric acid. PH. ALBRECHT. *Chem.-Ztg.* 53, 118-9(1929).—Take 10-20 g. of approx. 83% H_3PO_4 in a Pt dish, add 5 times this wt. of $AgNO_3$, heat carefully to 100-120° and maintain this temp. for 2 hrs. Place the dish in a Jena beaker, heat with HNO_3 till the melt dissolves, dil. with water, remove the dish and filter. Recover the Ag in the filtrate by pptn. with Cl^- . Ignite the ppt. very carefully in a Pt crucible, weigh and treat with HCl and H_2SO_4 . W. T. H.

Acidimetry of phosphorous acid in presence of indicators. T. MILOBEDZKI AND K. BORATYNSK. *Roczniki Chem.* 8, 554-62(562 French)(1928).—The titration of carefully prepared H_3PO_3 showed the first H replaced by Na at $pH = 3.5-3.6$ and the second H^+ at $pH = 8.5-8.6$, values slightly lower than those obtained by Kolthoff.

JAROSLAV KUČERA

Precipitation of Group II acids (the chloride group) in the presence of other acid radicals. LOUIS J. CURTMAN AND WALTER W. PLECHNER. College City of N. Y. *Chem. News* 138, 65-7(1929).—The acids of Group II (HCl , HBr , HI , HCN , H_2S ,

$H_2Fe(CN)_6$, $H_3Fe(CN)_6$, and $HCNS$) may be pptd. in the presence of other acid radicals by means of $AgNO_3$ soln. if the soln. has been treated with 10% of its original vol. of concd. HNO_3 . To make a preliminary test for Group II, take 50 cc. of neutral soly., add 1 cc. of 0.25 N $AgNO_3$ and 5 cc. of concd. HNO_3 . Heat and stir. W. T. H.

Poisoning by bittersweet (*Solanum dulcamara*). HAROLD LOWE. *Analyst* 54, 153-4(1929).—The Stas-Otto method of extg. alkaloid from viscera is satisfactory but as solanine, the poisonous principle, is insol. in ether and in $CHCl_3$, a final extn. with warm amylalcohol from ammoniacal soln. is necessary. The most useful tests on the mixed alkaloids are: (1) A concd. soln. of the alkaloids in amyl alc. sets to a jelly. (2) Phosphomolybdic acid gives a cream-colored ppt. (3) Fröhde's reagent gives a violet color. (4) HNO_3 gives a purple color on heating. (5) Vanadic-sulfuric acid gives a red color. (6) Ethylsulfuric acid gives a red color. (7) Concd. H_2SO_4 with Br aq. gives red colors forming in streaks. (8) Selenic-sulfuric acid gives a red color. (9) The hemolytic action on blood. Two instances of poisoning are mentioned: that of a foal and that of a cow. W. T. H.

Determination of small quantities of mercury in the presence of organic and inorganic compounds. R. ROBINSON. *Analyst* 54, 145-52(1929).—By pptg. Hg with H_3PO_4 , filtering and titrating with 0.01 N I_2 and $Na_2S_2O_3$ solns., good results were obtained with samples ranging from 0.002-0.04% of Hg. The results are generally 0.3 mg. too low owing to volatilization of Hg. To the Hg soln. in a 350-cc. Erlenmeyer flask, add water to make 200 cc. and adjust the acidity with HCl so that 5 cc. of 2 N HCl is present in excess. Add 2 g. of $NaCl$ and 10 mg. of filter paper pulp. Then add 30 cc. of H_3PO_4 (d. 1.137) and allow the soln. to stand overnight. In the morning, heat on the water bath for 15 mins. and allow to stand 20 mins. Filter through a well-packed paper-pulp filter and wash with cold water. Transfer the filter and ppt. back to the original flask, wiping the sides of the funnel with paper to remove all Hg. Add 100 cc. of water and 2 cc. of 30% $AcOH$, followed by at least twice as much 0.01 N I_2 soln. as is required by the Hg present and 2 g. of KI . Allow to stand for 30 mins. with occasional shaking and then titrate with $Na_2S_2O_3$ and I_2 solns. Allow for the vol. of I_2 soln. required to give the iodo-starch color. When org. matter is present, digest 0.2 to 0.5 g. of the substance with 10 cc. of concd. H_2SO_4 in a Kjeldahl flask heated to 130-150° in a paraffin bath. Occasionally add a little KNO_3 to hasten the process. Cause the fumes to pass through 2 wash bottles. When the org. matter is destroyed and the contents of the flask no longer smell of SO_2 , add the contents of the wash bottles to the main soln. and filter. Neutralize and continue as above. W. T. H.

Perchloric acid as an agent for the clean destruction of organic matter. R. J. C. FABRY. *Chemist-Analyst* 18, No. 2, 8-9(1929).—It is frequently necessary to destroy tartaric acid which has been added to prevent pptn. of $Fe(OH)_3$ or H_2TiO_4 . Add to 600 cc. of soln. 15 cc. of concd. HNO_3 and 10 cc. of 20% $HClO_4$. Allow to stand overnight. W. T. H.

Determination of the acetone group. AD. GRÜN. *Ber.* 62B, 473-4(1929).—The method described by Elsner (*C. A.* 23, 1394) does not do justice to the similar procedure described by G. (*C. A.* 20, 2659). W. T. H.

Estimation of mixtures of methanol and ethanol. STANLEY KETTLE. *Chemist-Analyst* 18, No. 2, 7(1929).—Oxidize with H_2SO_4 and $K_2Cr_2O_7$. This oxidizes $EtOH$ to $AcOH$ and $MeOH$ to CO_2 and water. Pass the evolved gas into ammoniacal $BaCl_2$ soln. Filter off the $BaCO_3$ and titrate with HCl to det. the $MeOH$. W. T. H.

Estimation of acetone in denatured alcohols. WM. L. O. WHALEY. *Chemist-Analyst* 18, No. 2, 6-7(1929).—To 10 cc. of alc. add water to make 1 l. Mix and pipet off 10 cc. into a 250-cc. measuring flask with ground stopper. Add 100 cc. of water, 10 cc. of 5 N $NaOH$ soln. and cool in ice. To the cold soln. add 50 cc. of 0.01 N I_2 soln. and keep in ice 2 mins. longer. Dil. and titrate with $Na_2S_2O_3$. W. T. H.

Notes on the iodometric determination of glucose. VINCENT A. TOSCANI. *Chemist-Analyst* 18, No. 2, 7(1929).—To prep. a sensitive starch paste, triturate 1 g. of sol. starch with enough satd. $NaCl$ soln. to make a paste. Then add 100 cc. of hot, satd. $NaCl$ soln. This indicator is sensitive and stable. If a reducing sugar is present in acid soln. it is important to have the soln. slightly alk. before adding the alk. ferricyanide soln. For this purpose add a few drops of phenol red and 25% $NaOH$ until the soln. is alk. Then to det. glucose add a measured vol. of standard $K_3Fe(CN)_6$ soln. and 3 cc. of a mixt. of 1 g. KI , 2 g. $ZnSO_4$ and 10 g. $NaCl$ in 40 cc. of water. Make acid and titrate with thiosulfate. W. T. H.

Critical comments on the analysis of glycerol by the acetin method and the sources of error. OTTO BEHRN. Hess. Chem. Prüfungstation Gewerbe, Darmstadt. *Chem.-Ztg.* 52, 597-8(1928).—The errors in the International Standard Method for detg.

glycerol (by the acetin method) were traced to the presence of CO_2 in the NaOH soln. employed. For the correction of these errors, cf. *C. A.* 22, 3863, 4410. W. C. EBAUGH

New method of colorimetric determination of *d*-glucose. A. B. SHAKHKELDIAN. Timiriazev Rural Econ. Tech. *J. Russ. Phys.-Chem. Soc.* 60, 1517-20(1928).—All quantitative methods of mono- and polysaccharide detns. being based on their transformation in *d*-glucose, the latter is usually determined by its ability to reduce Cu_2O to Cu^{++} . As, however, the relation between the quantity of Cu_2O obtained and that of glucose taken is not constant and depends on the degree of concn. of the solns., the duration of heating and other operating details, S. now proposes a new method of glucose detn. which is based on the development of red-colored picramic acid, $\text{C}_6\text{H}_3(\text{OH})(\text{NH}_2)(\text{NO}_2)_2$, by the action of picric acid on *d*-glucose in alk. soln., having previously established that the relation between the quantity of glucose taken and that of picramic acid obtained is const. Salt-free glucose solns. of various concns. were thus detd. in a Duboscq colorimeter by a comparison with a standard colorimetric soln., and the detns. were found correct within 1%. Glucose solns. usually contain NaCl due to neutralization of glucose hydrochloride by Na_2CO_3 and, since NaCl has an influence on the picramic acid coloration, a modification of the method is suggested which also gives exact results in the presence of salt. BERNARD NELSON

Identification of fructose in presence of other carbohydrates. L. EKKERT. *Magy. Gyógy. Ért.* 5, 17-8(1929).—Dissolve 0.01-0.02 g. of substance in 3-4 drops of KOH soln., add 0.5-1 g. of solid KOH or NaOH . In the presence of fructose a red ring appears around the solid alkali and slowly the whole soln. turns red. Other carbohydrates do not give this reaction. S. S. DE FINÁLY

Compounds of oxygenated halogen acids with benzidine (KRETOV) 6. Colorimetric measurements (EGNER) 2. The solubility of Reinsch Sb films in water (CLARKE) 2. Fatal phenobarbital poisoning. Report of a case with toxicologic analysis (WRIGHT) 11H.

8—MINERALOGICAL AND GEOLOGICAL CHEMISTRY

EDGAR T. WHERRY AND J. F. SCHAIERER

New mineral names and new data. W. F. FOSHAG. *Am. Mineral.* 14, 77-9 (1929); cf. *C. A.* 23, 1081.—A review of the properties and occurrence of the following minerals, with references, is given: monrepite, pseudoglaucophane and ferrothorite. New data are added on rhomboclase, szomolnokite, usbekite and tanatarite. A. M. B.

New data on atomic dimensions. EDGAR T. WHERRY. *Am. Mineral.* 14, 54-8 (1929).—A summary of recent work on at. dimensions is given in tabular form. The values are chiefly those deduced in the studies of V. M. Goldschmidt (*C. A.* 20, 2767, 3415) and Pauling (*C. A.* 21, 1434). W. prefers the term "atom-meter," symbol *am*, in place of "ångström." The application of the data to the study of replacements in minerals and in similar problems is briefly discussed. A. M. BRANT

Precision measurements of the lattice constants for various tetrahedrites. The formula and structure of tetrahedrite. FELIX MACHATSCHKI. Univ. Oslo. *Z. Krist.* 68, 204-22(1928); cf. *C. A.* 23, 1842.—Tetrahedrite is hextetrahedral and belongs to space group T_d^3 . The size of the unit cube varies with the compn. At. positions are given. The general formula is $R^I_4R^{III}_4\text{S}_4$, where R^I is chiefly Cu, and R^{III} chiefly Sb and As. There may be some replacement of R^I by R^{II} , usually Zn and Fe. In this case there is room in the structure for extra S. For ordinary tetrahedrite, Cu_4SbS_4 , $a = 10.32$ A. U.; with Ag replacing some of the Cu the value of $a = 10.40$; the substitution of As for Sb (tenuantite) gives $a = 10.19$; and the presence of some Bi replacing Sb causes a large increase in the size of the unit cube. L. S. RAMSDALL

The enargite group. Structure of sulvanite, Cu_3VS_4 . W. F. DE JONG. *Z. Krist.* 68, 522-30(1928).—Enargite, Cu_3AsS_4 , and famatinite, Cu_3SbS_4 , are isomorphous, and probably orthorhombic, but sulvanite is cubic. The space group is O_h^8 , with Cu at 24c, V at 8e, and S at 32a ($u = 1/8$). Eight mols. are contained in the unit cube, the edge of which is 10.750 ± 0.005 A. U. The calcd. d. is 3.97. This structure type is similar to that of bornite, Cu_5FeS_4 . An analysis of sulvanite gave Cu 51.20, V 14.20 and S 34.60%. L. S. RAMSDELL.

Pseudo-cubic quartz crystals from Artesia, New Mexico. W. A. TARR AND JOHN T. LONSDALE. *Am. Mineral.* 14, 50-3(1929).—Quartz crystals consisting dominantly of the + rhombohedron r , and closely simulating cubes, were found in the gypsum beds in the red sandy shale. They are most abundant in a zone just below the shale. Most of the crystals are colored by hematite, the color being dependent on the color of the gypsum. About 2% of the crystals are pseudo-cubic while the others are quartzoids or doubly terminated prisms. When the - rhombohedron s is present, its luster is less than that of the + form. Etching pits were found to have no definite orientation. The factor which prevented the development of the - form is not evident, but is probably of local distribution. A. M. BRANT.

The crystal structure of brookite. LINUS PAULING AND J. H. STURDIVANT. *Calif. Inst. Tech. Z. Krist.* 68, 239-56(1928).—Brookite, TiO_3 , is orthorhombic with symmetry V_h^{15} . There are 8 mols. in the unit cell, which has the dimensions $a = 9.106$, $b = 5.436$ and $c = 5.135$ A. U. At. positions are given, based on the assumptions that the structure consists of octahedra, with a Ti atom at the center and O atoms at the corners; that each octahedron shares 3 edges with adjacent ones; and that the Ti-O distance is about 1.95 A. U. L. S. RAMSDELL.

The structure of sillimanite and mullite. W. H. TAYLOR. *Manchester Univ. Z. Krist.* 68, 503-21(1928). (In English).—The unit cell of sillimanite is orthorhombic, with $a = 7.43$, $b = 7.58$ and $c = 5.74$ A. U. This cell contains 4 mols. of Al_2SiO_5 , and the symmetry is approx. that of V_h^{10} . An at. arrangement is proposed in which each Al atom is surrounded by 6 O atoms, and each Si atom by 4 O atoms, forming definite SiO_4 groups. The unit of mullite is 4 times that of sillimanite. Four cells of sillimanite would have $\text{Al}:\text{Si}:\text{O} = 32:16:80$, while one mullite would have $\text{Al}:\text{Si}:\text{O} = 36:12:78$. By substituting 4 Al for 4 Si and removing 2 O atoms, a very slight readjustment of positions gives the mullite structure. A similar situation exists with $\text{Na}_4\text{Ca}_2\text{Si}_2\text{O}_{10}$, which is cubic with 4 mols. in a cell with $a = 7.49$ A. U. and with $\text{Na}_4\text{Ca}_2\text{Si}_2\text{O}_{10}$, which is pseudo-cubic, with 2 mols. in a cell with $a = 7.54$ A. U. Equiv. units therefore contain $\text{Na}_4\text{Ca}_2\text{Si}_2\text{O}_{10}$ in the first case and $\text{Na}_4\text{Ca}_2\text{Si}_2\text{O}_{10}$ in the second. Kaolinite is entirely different from either mullite or sillimanite because in it $\text{Al}:\text{Si}:\text{O} = 36:12:108$. L. S. RAMSDELL.

Garnets. J. STEPH. VAN DER LINGEN. *Univ. of Cape Town. S. African L. Sci.* 25, 10-5(1929).—An address. ALBERT L. HENNE.

The chemical composition of apophyllite. B. GOSSNER AND O. KRAUS. *Z. Krist.* 68, 595-615(1928).—Analyses of apophyllite from 4 localities are given, and the formula obtained is $4(\text{Si}_2\text{O}_5\text{H}_2.\text{CaO}_2\text{H}_2)\text{KF}$, in which the F is replaceable by OH. Variable replacement in a single crystal may cause a zonal structure. As the formula indicates, the H_2O is not zeolitic, but is firmly held, and cannot be removed without destroying the structure. The unit cell contains 4 mols., and has the dimensions $a = 15.84$ and $c = 15.84$ A. U. The space group is D_{2h}^{12} . At. positions are given. L. S. RAMSDELL.

The structure of analcite. JOHN W. GRUNER. *Univ. of Minn. Z. Krist.* 68, 363-78(1928).—This article gives more complete data than a previous one (*C. A.* 22, 3116). Analcite dehydrated by heating to 700° shows very little structure alteration, the cube edge merely changing from 13.64 ± 0.05 to 13.59 ± 0.05 A. U. L. S. RAMSDELL.

Studies of chlorite. A. BIANCHI AND T. CARPANESI. *Univ. of Padua. Atti Ist. Veneto* 87, Part II, 145-60(1927-8).—A preliminary study of the dehydration of chlorite. B. and C. used an elec. furnace with a Pt/Pt Rh thermocouple and a direct-reading millivoltmeter. Penninite from Zermatt and clinochlorite from Punta della Rossa (Val Devero) show analogous behavior on dehydration with increasing temp. The curves show 3 sections, $15-480^\circ$, $490-520^\circ$ and $690-730^\circ$. The results point to a stable anhydride at 520° and 690° . Serpentine from Snarum and antigorite from Valsovaranche behave differently from chlorite. S. L. B. EHERTON.

Camsellite and szaibelyite. A. N. WINCHELL. *Am. Mineral.* 14, 48-9(1929).—Camsellite was found to be in microscopic lath-shaped crystals with X parallel and Y normal to the laths. A method of handling these laths is described. Camsellite was

found to be biaxial —, with $\gamma = 1.649$, $\beta = 1.620 \pm 0.005$, $\alpha = 1.575$; $2V = 80^\circ$. According to the best available data, szaibelyite is uniaxial —, with $\omega = 1.65 \pm$, $\epsilon = 1.58 \pm$. Hence the 2 minerals cannot be the same even if there is no chem. difference (cf. Schaller, *Am. Mineral.* 13, 230). By the same method *sussexite* was found to be biaxial —, with a small optic angle; $\gamma = 1.712 \pm 0.003$, β slightly higher than 1.70, $\alpha = 1.6388$, $\gamma - \alpha = 0.073$.

A. M. BRANT

The crystal form of calcium sulfate. L. S. RAMSDALL AND E. P. PARTRIDGE. *Am. Mineral.* 14, 59-74(1929).—X-ray diffraction patterns indicate the existence of 3 crystal forms of CaSO_4 , gypsum, the hemihydrate, and anhydrite. "*Soluble anhydrite*" is identical in crystal structure with the hemihydrate, the latter apparently belonging to the zeolitic class of substances, which lose and regain water of hydration without change in crystal structure. The equil. diagram of $\text{CaSO}_4 - \text{H}_2\text{O}$, compiled from various sources, is given and discussed. The transition temp. for the change from gypsum to anhydrite when in contact with H_2O is provisionally placed at 38° ; for the change from gypsum to hemihydrate when in contact with H_2O it is more definitely placed at 98° . Anhydrite has been experimentally obtained from gypsum in contact with H_2O at 100° , and gypsum from anhydrite in contact at $11-15^\circ$. In both cases there was evidence of setting similar to plaster of Paris. These conversions are analogous to that of hemihydrate to gypsum noted in the setting of plaster. In each case a more sol. unstable phase dissolves in H_2O with subsequent crystn. of a less sol. stable phase. A list of references is given.

A. M. BRANT

Relations of electrode potentials of some elements to formation of hypogene mineral deposits. B. S. BUTLER AND W. S. BURBANK. *Am. Inst. Mining Met. Eng., Tech. Publ.* 166, 3-15(1929).—The relation of the electrode potentials of the elements to their occurrence in hypogene ore deposits is brought out. Electrode potentials indicate certain fundamental properties having a direct and controlling influence on oxidation-reduction reactions. Such reactions are believed by B. and B. to have a vital bearing on ore deposition. Arranged in the order of their electrode potentials, the groups of elements show a periodicity and a definite and striking relation to their occurrence in primary ore minerals. Elements in each group with electrode potentials above +1 occur only in O combinations, those with — potentials as sulfides, allied minerals or native metals. Elements falling between the 2 groups occur both as O minerals and as sulfides. In ore deposits the O minerals of this intermediate group begin to form before the sulfides. The electrode potential of the sulfide ion falls in the intermediate group, and under conditions that would cause Fe^{++} to be oxidized to Fe^{+++} , the sulfide ion would probably be raised to a higher state of oxidation. The presence of barite and other sulfates formed before sulfides indicates that the S is, in part at least, in a very high state of oxidation prior to the deposition of sulfides. As some of the metals were present as oxidized compds. before they were deposited as sulfides, it is questioned whether most of the metals were not transported as oxidized compds. rather than as sol. sulfides. The groups of elements are deposited in the order of their potentials, and within the range of simple sulfides the metal sulfides tend to be deposited in the order of their potentials. Certain practical results are pointed out: if a vein contains Fe^{+++} minerals that have not been attacked or altered by the ore solns., the conditions are not favorable to the deposition of sulfides, and the latter are likely to decrease toward the source of the solns. Among the sulfide minerals there is an order of deposition from higher to lower temp. that corresponds with the electrode potentials of the metals.

ALBERT L. HENNE

Silver-bearing minerals of some ores from the Tintic Mining District. A. W. HAHN. *Am. Inst. Mining Met. Eng., Tech. Publ.* No. 202, 7 pp.(1929). E. H.

Field observations of electric resistivity and their practical application. J. G. KOENIGSBERGER. Univ. of Freiberg. *Am. Inst. Mining Met. Eng., Tech. Publ.* No. 129, 17 pp.(1928).—Practical applications are made (1) in the detn. of the continuity of a conducting orebody, (2) in the detn. of the surface area of an orebody, and (3) in the detection of a water-bearing fault in a salt mine. Observations are now given (1) on the influence of the depth of a ground-water table, (2) on the detection of gas under high pressure in coal seams. Two plane circular electrodes of Fe or brass are applied to the rock, a contact substance being used and the resistivity is measured on a Wheatstone bridge. The contact substance is powd. hematite with an aq. soln. of FeCl_3 and FeSO_4 or NaCl . Lab. detns. of resistivity of rocks are not useful in geophysics, and the detn. must be made in situ. The methods used in practice in solving various problems are described in detail.

S. L. B. ETHERTON

A comparison of the ore deposits of Långban, Sweden, with those of Franklin, New Jersey. CHARLES PALACHE. Harvard Univ. *Am. Mineral.* 14, 43-7(1929).—

A paragenetic classification of the Långban minerals (after Magnusson) is given. The principal ore minerals of the 2 localities are different and Zn is wholly absent from the Långban ores. The Mn-rich skarn present in large quantity at both is due at Långban to regional, and at Franklin, to contact metamorphism. The rarer elements, Pb, As and Sb seem to have been introduced with the ore at Långban, while at Franklin the comparable elements Pb, As, Cl and S came in with the later pegmatite.

A. M. BRANT

Venezuela of today. NOEL G. HACKNEY. *Mining J.* 164, 138-9(1929).—A brief account of the operating gold companies in Venezuela, with a map showing their location.

ALDEN H. EMERY

Diatomite, its occurrence, preparation and uses. V. L. EARDLEY-WILMOT. Canada Dept. of Mines, *Mines Branch*, No. 691, 180 pp.(1928).—A description of the world's occurrences of diatomite (Canadian in detail); methods of mining, prepn and manuf.; and the properties and uses of the raw and mfd. product. A 7-page bibliography is included.

ALDEN H. EMERY

Investigations of mineral resources and the mining industry, 1927. I. Bituminous sands of northern Alberta—experimental drilling and paving operations, 1927. S. C. ELLS. Canada Dept. of Mines, *Mines Branch*, No. 694, 60 pp.(1928); cf. C. A. 21, 42.—Detailed logs of 4 exploration wells, the equipment used and the methods recommended are given. The 1927 paving operations are described and costs estd. With reasonable freight rates and markets justifying adequate capital expenditure, the cost of road surfaced with bituminous sands should be materially less than other competitive methods.

ALDEN H. EMERY

Composition of Siberian bogheads in connection with the geological theory of their formation. G. L. STADNIKOV AND A. E. WEITZMAN. *J. Russ. Phys. Chem. Soc., Chem. Pt.*, 60, 1123-31(1928); G. L. STADNIKOV AND Z. I. VOZZHINSKA. *Kupor Chem. Inst. Ibid* 1133-6; cf. C. A. 22, 4417, 4418.—For the purpose of establishing the final products of transformation of fatty acids in the course of geologic period, a systematic study of the compn. of 2 different varieties of Irkutsk (Siberia) bogheads was made, the theory being that they were formed by bituminization of fats and alae waxes. 800 g. was taken from each of the 2 samples and both were subjected to the same treatment, which consisted in an extn. with C_6H_6 , followed by an exhaustive extn. with $CHCl_3$, after which the undissolved residues were repeatedly extd. first with boiling alc. NaOH, then with boiling NaOH soln. in isoamyl alc. and finally washed with C_2H_5OH and with H_2O . The C_6H_6 ext., which represented 1.6-1.8% of the samples, consisted of satd. and unsatd. univalent fatty acids contg. 12-22 atoms of C per mol., and also of some tar. The $CHCl_3$ ext., 0.46% of the quantity of the bogheads, consisted of a black tar, which has not been examd. The alc. and isoamyl alc. NaOH exts. were formed of soaps and fatty acids. Conclusion: Bogheads are products of profound polymerization and anhydriization of fatty acids. No wax was obtained in any of the exts., whereas peats and brown coals yielded waxes under similar conditions. B. N.

The temperatures of magmas. ESPEER S. LARSEN. *Am. Mineral.* 14, 81-94 (1929).—Available evidence from field and lab. petrology, geophysics and phys. chemistry seems to justify the conclusions that some basaltic magmas have temps. below 870° , many are below 1000° , very few are as high as 1200° , and probably most are not far from 800° to 900° . Rhyolitic magmas have lower temps., all being above 870° and below 870° . Nearly all are below the temp. of decompn. of biotite, about 870° , and that of common hornblende, about 750° . Probably most rhyolitic magmas have temps. in the neighborhood of $600-700^\circ$.

A. M. BRANT

Etna and its lava. A. RITTMANN. *Vulkaninst. Immanuel Friedländer, Neapel Naturwissenschaften* 17, 94-100(1929).—A short review is given of the types of eruption of Etna. The chem. compn. of the lavas is given in a table; mineralogically they contain plagioclases and augites with little olivite and nephelite. The compn. is SiO_2 49 to 58, Al_2O_3 17 to 20, Fe_2O_3 2.7 to 3.7, FeO 4.3 to 6.8, MnO 0.11 to 0.16, MgO 1.2 to 4.7, CaO 5.0 to 10.0, Na_2O 4.4 to 5.8, K_2O 1.6 to 2.8, TiO_2 1.3 to 2.0, P_2O_5 0.5 to 0.8% for 5 different types of lava. From geological data, changes in compn. of erupted lava with time are plotted in curves for the equiv. amts. of acids and bases. It appears that SiO_2 , Al_2O_3 and alkali have gone through a max., *fm. i. e.*, Fe, Mn and Mg oxides, and *c. i. e.*, CaO , through a min., both extremes lying in the Trifoglietto lava (prehistoric). At the present time the compn. is again almost as it was in the pre Etna (Pleistocene) lava.

The origin of the Mediterranean red earths (Terra rossa). A. REIFENBERG. *Kolloid Chem. Beihefte* 28, Nos. 3-5, 55-147(1929); cf. *C. A.* 22, 2424.—A discussion of the influences affecting the formation of the red earths is followed by an exposition of the colloid chem. aspects of silicic acid protective action on the $\text{Al}(\text{OH})_3$ and $\text{Fe}(\text{OH})_3$ gels present.

The formation of red soil and of black vlei soil from dolerite at Salisbury, Southern Rhodesia. H. B. MAUPF. *Geol. Survey S. Rhodesia. S. African J. Sci.* 25, 156-67 (1929).—This article is chiefly geological, but includes chem. analyses of the various soils.

Relations between submarine sediments and the condition of the surface water. J. THOULET. *Inst. Españ. Oceanografía. Notas Resúmenes* 2, No. 5, 26 pp.(1924).—The filling of the ocean is effected (a) in the shallow parts near continents, by erosion, and (b) more remote from land, by dust carried by the wind and by CaO and SiO_2 deposits from animal or vegetable plankton. Murray's law, that the CaCO_3 content of a sediment varies inversely with the depth, is refuted by T. The bottom of the ocean differs greatly with locality and with time of observation.

The evidence of the kimberlite pipes on the constitution of the outer part of the earth. PERCY A. WAGNER. *S. African J. Sci.* 25, 127-48(1929).—The evidence obtained independently from seismic, astronomical, phys. and geological data leads to the conclusion that the earth exhibits gravitational stratification, being made up of a succession of concentric silicate shells, the d. of which increases progressively inward, surrounding a thick core of Ni-Fe. Between this core and the innermost silicate shell there is, according to certain geologists, a shell composed partly of Ni-Fe and partly of heavy silicates. Many also postulate the existence of a universal layer of basalt some 17 km. in thickness beneath the outermost silicate shell from which the vast outpourings of the plateau-basalts are presumed to have come. Kimberlite pipes with which the southern half of Africa is riddled afford valuable direct evidence in regard to the earth's outer shells. This is supplied mainly by the abundant xenoliths brought up from below by the kimberlite magma which originated at a depth of at least 60 km. The deep-seated rocks represented among the xenoliths include amphibolites of several types, gabbro, pyroxene, granulite, eclogite and a great variety of peridotites. There are 2 main types of eclogite corresponding with those differentiated in the Norwegian Archean. There is a complete absence among the xenoliths of any that could be referred to the hypothetical basaltic substratum, indicating that this does not exist beneath southern Africa. The granitic crust is apparently underlain by a shell composed predominantly of ortho-amphibolites accompanied by gabbroid and granulitic rocks. The lower-most part of the shell is believed to be occupied by a continuous layer of gabbroid eclogite in the form of basalt or basaltic glass. This in turn, is underlain by a universal peridotite or *sima* zone in which there are bands and lenses of pyroxenite and eclogite, both of types allied to peridotite. The chem. compn. and Ra content of the eclogites found in kimberlite do not support the hypothesis that these deep-seated eclogites are piezo-cryst. facies of plateau-basalt. Down to the depth at least from which kimberlite is derived, the deeper substratum consists predominantly of peridotite and not of eclogite. The universal layer of basaltic compn., the existence of which is sometimes considered as necessary to explain the surface history of the earth, may be represented by the hypothetical amphibolite-gabbro-granulite shell underlying the continental crust; the rocks composing the shell are all magmatically identical with basalt. On this view, which at present rests on a very slight foundation, the amphibolite-gabbro-granulite shell constitutes a vast potential reservoir of basaltic magma, and the plateau-basalts are to be ascribed to the periodic fusion of parts of the shell through the accumulation of radio-thermal heat, according to the hypothesis of Joly.

The biochemistry of iodine and the iodine cycle in nature. GULBRAND LUNDE. *Sætertrykk Norges Apotekerforenings Tids.* 1928, 1-17; cf. *C. A.* 23, 401, 1845.—The geochem. aspect of I is considered in view of the assumption that during the cooling and congealing process of the constituents of the earth, a segregation of the elements into several concentric zones (phases) took place. Besides the 4 inorg. phases there is an org. phase or biosphere in which all the life on earth developed, and in which the I concn. was greater than in any of the other phases, i. e., there was a greater striving for I by organisms. Three diagrams are given to show the I cycle in nature. I is continually liberated in the weathering of rocks, and a part of it is carried into the ocean and fresh waters, some into the soil, and some into the atm. Plants obtain I from the soil, and animals get it from plants. Fresh water plants are richer in I than land plants. The I concn. is higher in the ocean (0.02 mg. per l.) than in fresh water. Marine plants and animals contain more I per unit wt. than plants and animals of the land or fresh water.

Attention is called to (a) the high I concn. in (dry) plankton (10,000 times as great as in the ocean), (b) the I concn. in the human blood (0.1 to 0.15 mg. per l.), (c) the physiol. function of the thyroid glands, (d) the chemistry of thyroxine, (e) the prevalence of goiter in certain districts being inversely proportional to the I concn. in the available foods, (f) the amt. of I required per person per day (0.05 to 0.10 mg.). Also in *Chem. Reviews* 6, 45-61(1929).

J. BALOZIAN

An attempt to explain flotation processes by means of osmotic and solution pressures. C. BRUCHHOLD. *Metall u. Erz* 25, 610-8(1928).—A theory of flotation is developed offering an explanation for the presence of sulfides in the scum and gangue minerals in the slime, and based on the soln. pressure of the ore particles and the osmotic pressure of the slimes. Considerations show that the greater the excess of soln. pressure of a sulfide particle over the osmotic pressure of the slime the less is the flotation power of the ore. Further, it is shown that this power of an ore is a function of the soln. pressure of the sulfide particles (those with high pressure are floated with more difficulty than those with low) and the velocity of flow of the slime through the flotation machine. The change of the osmotic pressure and the use of alkali on the flotation is discussed.

J. BALOZIAN

Determination of alkalinity or acidity of pulp in the flotation process. C. BRUCHHOLD. *Bol. Minero (Mex)* 27, 106-17(1929).

E. M. SYMMES

Examination of Swedish tar oils for flotation. KARL RUTBERG. *Jernkontors Ann.* 82, 1-21(1927).—Flotation tests on Zn and Pb ore with tars and oils show that tars with a large distn. residue up to 240° give the largest concn. of sulfides. Tars with over 70% residue have generally given better results than tars with less residue. The residue can profitably go up to 80%, and 10% of the tar ought to distil between 200 and 240°. The frothing power of the tar can be increased by keeping it in open containers. The fraction which is best adapted to froth formation in flotation distills at about 200 to 210°. The lower fractions give less froth, and can often hinder the flotation process.

A. DROGSETH

Ore dressing tests to recover manganese in rhodochrosite ores. F. D. DE VANNEY AND WILL H. COGHILL. Miss. Valley Expt. Sta., Rolla, Mo. Bur. Mines, *Repts of Investigations*, No. 2902, 4 pp. (1928).—Differential flotation, gravity, concn. and magnetic concn. were applied to an ore contg. 40% rhodochrosite. Xanthate and pine oil floated the sulfides while soap flotation removed the $MnCO_3$. The sulfide concentrate contained 8.1% Pb, 18.4 of Zn and 21.3 of Fe. A satisfactory sepn. of the $MnCO_3$ on a lab. scale was secured at a cost of 15 cents per ton for reagents. Gravity concn. through 10 mesh gave a loss of 12.4% of the Mn in 55.4% of the insol. Magnetic concn. gave a promising sepn. of the $MnCO_3$. A composite of fine concentrates, secured by increasing the strength of the magnetic field in steps, contained 45% of the Mn. J. W. SIMPLEY

The reduction of alkaline-earth sulfates in metallurgical operations. G. CHARPY AND L. JACQUE. *Compt. rend.* 188, 473-5(1929).—In certain metallurgical operations, $BaSO_4$ does not combine with S as much as $CaSO_4$. This is due not to a difference in chem. properties of the two sulfates, but to certain phys. particulars.

FRANK V. JOHNSON, JR.

Heat utilization in metallurgical plants. L.-H. STCHEPINE. *Chaleur ind.* 9, 217-22(1928).—Every percentage of moisture prolongs the coking period by 1% and increases the expenses of cooling and draft by 3%. There is a loss of heat by radiation

from the walls and in the hot gases from the coking chamber, amounting to 400,000 cal./ton. For the blast furnace, the slag removes 4-5% of the total heat put in, and the melt removes 3%. Other losses are discussed and a heat balance is drawn up. The utilization of gas heating, the Martin furnace, the rolling mills and auxiliary services are treated.

Copper-cuprous oxide eutectic in copper refining. W. STAHL. *Chem.-Ztg.* 53, 137(1929).—It is shown that an alloy contg. 96.5% Cu and 3.5% Cu_2O , or 99.62% Cu and 0.39% O (cf. Heyn, *Z. anorg. Chem.* 39 (1904) is present in Cu refining furnaces during the "poling period". Samples taken at that time have a stem-like instead of a fibrous structure, and show 0.35 to 0.39% O and 99.6 to 99.7% Cu.

W. C. EBAUGH

Development of high-duty cast iron. F. D. CORBIN. *Foundry Trade J.* 40, 83 4(1929).—The fundamentals of the phys. metallurgy of cast Fe are explained in order to understand more clearly the newer processes developed for the production of high-grade cast Fe.

DOWNES SCHAAF

The use of scrap in gray iron, malleable, and electric steel mixtures. E. K. SMITH AND F. B. RIGGAN. Stockham Pipe & Fittings Co., Birmingham, Ala. *Am. Foundrymen's Assoc.* (preprint), No. 29-3, 51-70(1929).—The use of scrap metal in foundries is an economic necessity, and may cause trouble, or improved quality of product, depending on the melting practice. Careful sorting of scrap, and definite specifications, are essential. The proper size classifications for cupola practice are discussed. Expts. showed that cupola charges might contain up to 75% scrap without bad effects. Burned material or borings in the cupola gave gray Fe that contained numerous fine inclusions, and should be used only in the blast furnace. A little Sn or Zn in cupola charges was not detrimental. Thorough mixing of the molten Fe is important. Steel scrap in gray Fe increases the strength. In scrap for malleable Fe, alloy steels, especially Cr, must be avoided. Rusty scrap should be avoided in acid elec. charges, but not necessarily in basic. By the use of Na_2CO_3 as a flux, the S content of gray Fe from scrap charges can be reduced, and slag inclusions also may be removed.

G. F. C.

Application of nitriding to the surface hardening of steel. ARMY TECH. STAFF OF OSAKA ORDANCE. *Bull. Ordnance* 6, 469-512(1928).—Cr-Mn, Cr-Ti, Si-Mn, various C-steels, Cr steels, etc., totaling 10 kinds in all, were annealed and nitrided by passing NH_3 gas at 560-760°, for 5-30 hrs. in an elec. furnace. Above 610°, Fe_3N is formed on the surface which makes the material brittle. For obtaining a hard and tough surface, the temp. must be between 560° and 610°. Nitriding goes deeper by long treatment, but it is difficult to increase the hardness of the surface, the longest time of treatment which is practically useful being 15 hrs. The Brinell, Shore and Martens hardness were measured with the samples heated for 5, 10 and 15 hrs., the microscopic observation of the samples being made at the same time. Results obtained with Brinell or Shore hardness are generally inaccurate. The steel which is best fitted for surface hardening by nitriding is Cr steel with a low C content; next comes very mild steel. High-C steels are not suitable.

K. SOMEYA

Investigations on molding sands. H. NIPPAR AND E. PIWOWARSKY. Tech. Hochschule Aachen. *Giesserei* 15, 1097-1108(1928).—The effect of the clay and moisture content, and of the size and shape of the grain on the permeability to gases of molding sands are investigated. With increasing clay content the max. permeability of the sand increases, the greatest permeability occurring at a definite clay content. With higher clay content at the max. the moisture is higher, for the same grain size,

being clearer with coarse than with fine grains. For coarse grains with the same clay content, the max. permeability is greater for the sharp than for the rounded grains. There is a pronounced max. for these sands, depending on their clay and H_2O content. The susceptibility of the sand mixts. to H_2O is less with coarse than with fine-grained sand. Further expts. are made to det. the change in permeability on complete drying of the mold.

J. BALOZIAN

Drying and cooling by adsorbents. CONSTANTIN REDZICH. *Apparatebau* 41, 37-9(1929).—Remarks on the advantages of silica gel as a driver for blast-furnace air, with a table showing economies effected in a furnace of 1330-ton output per week.

J. H. MOORE

The blast-furnace theory. RICHARD FRANCHOT. *Am. Inst. Mining Met. Eng., Tech. Publications*, No. 170, 3-20 pp.(1929).—A review of the theories of reduction of Bell and of Johnson is followed by the statement of the N hypothesis, which is in effect that as the blast heat is increased and the combustion temp. tends to rise, this effect is increasingly offset by increasing N activity; the difficulty of raising the hearth temp is increased by a resistance assocd. with the combustion itself. The effectiveness of the high blast heats now in common use is in substantial measure curtailed by an endothermic formation of N compds. in the combustion zone. Several supporting facts for this theory have been published and apparently the only objection is based upon the ground that certain measures of CN concn. made at a southern furnace fail to show substantial amts. of CN vapor in the hearth gases and suggestion is made that means of detg. the KCN concn. in this case might result in very low results. W. H. BOYNTON

New theory of the blast furnace process. II. F. WÜST. *Stahl u. Eisen* 48, 1273-87(1928); cf. C. A. 23, 71.—The literature on the oxidizing zone in front of the tuyères of a blast furnace is reviewed and a great no. of references are given. The presence of an oxidizing zone in front of the tuyères is assumed. Some of the Fe is reoxidized during its downward pass through this zone. FeO is continuously supplied to the slag, and is again reduced by the constituents of the pig Fe. As long as the slag contains a certain amt. of FeO which is easily reduced, no reduction of the oxides which are more difficult to reduce, such as SiO_2 and MnO , takes place. Consequently, the molten Fe bath cannot take up any Si or Mn. The old conception that these oxides are first reduced by the C from the molten slag, then the Mn and Si taken up by the molten Fe bath cannot be correct. The alloying constituents of the pig Fe are reduced and taken up above the tuyères. The Fe pellets suspended in the slag, obtained from 5 charcoal and 1 coke blast furnace, show as a rule a higher percentage of impurities than the pig Fe tapped from the same blast furnace. The compn. of these samples obtained during the working of the furnace proved conclusively that the pig Fe is formed above the tuyères. Lab. tests showed, furthermore, that SiO_2 and MnO can be reduced below the temp. of pig Fe and the alloying constituents can be taken up by cementation. In a H atm. at 1100° Fe absorbed 0.8% Mn from MnO in 7 hrs. At 1200° in a CO atm. it absorbed 3.8% Mn and 0.27% P. At 1170° in contact with C it absorbed in 5 hrs. 8% P, 5% Mn and 2.5% Si from their resp. oxides. From 9 cold blast furnaces, samples were taken from in front of the tuyères. Depending upon the type of the operation of the blast furnace the granules contained up to 60% Mn, 8% Si and 5% P. The higher amt. of these alloying elements showed that they could not have been taken up by the pig Fe in the short distance between the melting zone and the tuyères. They were taken up by the Fe in the solid state through cementation. The compn. of the samples taken during the regular working of the furnace showed that the formation of the pig Fe is already complete above the tuyères. The 173 samples taken during stops contain on the av. more Si than the tapped pig Fe samples. Part of the Si is, therefore, being burnt up either by the O of the hot blast in front of the tuyères or by the O of the FeO in the hearth. Under normal working conditions more Si is being introduced in the Fe than would be warranted by the final compn. of the pig Fe. The oxidizing zone reduces the efficiency of the furnace; every method eliminating this zone or decreasing its size will result in better operation.

J. A. SZILARD

An especially well-crystallized blast-furnace slag. (Mellite-schefferrite-olivine.) FRANZ ANGEL. *Z. Krist.* 68, 157-76(1928).—A thin section of the slag shows 55% mellite and 45% of pyroxene, olivine and glass, with the ratio of pyroxene to olivine about 3:1. According to the fractional chem. analysis the mellite consists of 70% $(Ca_2Al_2Si_2O_{12})$ and 30% akermanite $(Ca_2Mg_2Si_2O_{12})$, the pyroxene approximates scheferrite; and the olivine consists of 65% Mg_2SiO_4 , 30% Mn_2SiO_4 and 5% Fe_2SiO_4 . This slag is compared with other slags and with natural rocks.

L. S. RAMSDELL

The effect of barium oxide on the desulfurizing power of blast-furnace slag. C. E. WOOD AND T. L. JOHNSON. *Am. Inst. Mining Met. Eng., Tech. Publications*,

181, 3-19 pp.(1929).—A brief rept. of exptl. work to det. any increased desulfurizing action of blast-furnace slag due to BaO. The incomplete data tabulated and discussed indicate that: (1) percentages of BaO up to 5% do not markedly increase the desulfurizing action of the slag though it increases the molar basicity of the slag and increases its desulfurizing action; (2) the desulfurizing action of blast-furnace slag varies directly with its molar basicity; (3) the desulfurizing action of a slag is more closely related to the molar ratio of bases to acids than to basicity based upon percentages of bases and acids present; (4) desulfurization of metal by contiguous layers of slag was almost directly proportional to time of contact over a period of 60 mins.; (5) surface contact between slag and metal has an important bearing on desulfurization; (6) BaO is about $\frac{1}{3}$ as effective as an equal wt. of CaO in removing S and in fluxing SiO_2 and Al_2O_3 .

W. H. BOYNTON

Quality of pig iron and castings as affected by blast-furnace practice. A. I. BOEGEHOLD. General Motors Corp., Detroit. *Am. Foundrymen's Assoc.* (preprint), No. 29-5, 91-152(1929).—Eleven casts from 7 blast furnaces were tested for variations in properties, and used for making cast-Fe flywheels contg. 3 to 3.3% C, 2.25 to 2.35% Si, and 0.55 to 0.75% Mn, the cupola conditions in remelting being kept as const. as possible. Specimens for tensile, transverse, hardness, fluidity and shrinkage tests were also cast from each kind of pig Fe. Variations in atm. conditions must be allowed for. The large variations in blast-furnace operating conditions are described fully. These are due largely to differences in the quality of the coke, causing varied rate of combustion, speeds of descent of the charge, and outputs of pig Fe. The moisture in the blast is also very influential. The excessive air required by a slow-burning coke causes too much oxidation of the Si and C in the pig Fe in front of the tuyères. Pig Fe made under different furnace conditions, though of fairly similar analysis, showed decided differences in microstructure, fracture, and dilation-temp. curves, which are all illustrated. On heating to 930°, and cooling, the permanent growth of different lots of Fe varied between 0.052 and 0.024 in., resp. Each lot was used in the cupola for 3 weeks, and test-bars were cast when the influence of the preceding lot on the return scrap had been eliminated. All test-bars were cast at 1330 to 1370°. The design of each bar is shown, and the method of test described. The plotted results indicate trends rather than definite correlations, since it was impossible to vary only a single factor at once. High moisture content of the cupola blast increased the tendency of the Fe castings to have a chilled structure and higher combined C. A higher relative rate of production in the blast furnace gave Fe which shrank less, presumably because of its O or gas content. The dilation characteristics of the pig Fe were maintained practically the same after remelting in the cupola, but there was little individual variation in the dilation curve within any one lot. Machinability was better with less H_2O in the blast, and with well-deoxidized pig Fe, or pig Fe not produced too fast. Some lots of pig Fe gave considerable variation in Si content of different cupola melts, while with other lots the Si remained nearly const. Pig Fe from different lots differed greatly in hardness, though cast to the same section, and contg. the same amt. of Si. The tensile strength decreased, and the deflection increased, with the total C plus $\frac{1}{4}$ the Si content, but the different lots of Fe differed greatly in strength under the same conditions. The cast Fe cooled more quickly in dry-sand than in green-sand molds. The shrinkage was the same in nearly all lots; the fluidity varied, but the causes of variation were not detd. The results showed that the phys. character of pig Fe is influenced by conditions in the blast furnace, and is retained on remelting in the cupola. Classification of pig Fe according to the characteristics detd. by the blast-furnace practice is advocated. Variations in that practice must be controlled to secure pig Fe of uniform quality. The app. and procedure for a combustibility test for coke are described in an appendix. Also in *Foundry* 57, 322-5, 330(1929).

Modern open-hearth practice in Germany. FRIEDRICH STEIN. *Blast Furnace & Steel Plant* 17, 409-14(1929).

E. H.

Basic open-hearth yields. C. D. KING. *Am. Inst. Mining Met. Eng., Tech. Publications* No. 186, 3-38 pp.; *Iron Age* 123, 596-8(1929).—A discussion purporting to stimulate the discussion and study of chem., phys.-chem. and metallurgical phases of cooperation and their relation to ingot yields. Losses are defined and calcd. Conclusion: For any given charge and desired slag analysis of steel there is a definite yield, varying largely with scrap produced and miscellaneous losses. The best yield does not necessarily produce the lowest ingot cost. This depends entirely on relative prices of materials making up the gross metallic charge for equal scrap recovery and the difference in cost in converting any type of metallic charge to ingots.

W. H. BOYNTON

Unreduced oxides in pig iron and their elimination in the basic open-hearth furnace.

C. H. HERTY, JR., AND J. M. GAINES, JR. *Am. Inst. Mining Met. Eng., Tech. Publications* No. 165, 3-20(1929).—Five open-hearth steel heats were made using Fe from a blast furnace, 3 from casts made when the furnace was operating normally, and 2 from casts made when the burden was increased to throw the furnace on the cold side. The operation of the blast furnace and open-hearth was followed closely, a large no. of samples, temp. readings and other data being taken. While the test results are not sufficient to correlate bad Fe with trouble in the finished steel, they do prove that the silicates in the Fe are higher when the blast furnace is operating irregularly than when it is running steadily, and that the higher the silicates are in the Fe the higher they are in the steel.

DOWNES SCHAAF

A study of a thirty-six inch cupola. F. B. COYLE. *International Nickel Co., Bayonne, N. J. Am. Foundrymen's Assoc.* (preprint), No. 29-2, 21-50(1929).—Details of the practice and results from 14 heats of gray Fe for Diesel-engine castings are given and the progressive changes during each heat are plotted in the form of graphs. The compn. was planned to be about 3.2% C, 1.2% Si and under 0.2% P in order to obtain the max. mech. properties. The cupola was lined to 36 in. diam.; the crucible held 3000 lbs. of molten Fe; there were 4 tuyères, each 4 by 14 in. The following conclusions and correlations were deduced from the results: The temp. of the metal tapped increased as the heat progressed, and also with the use of limestone as a flux. The S content was increased by accumulation of slag; the C and Si contents decreased as the heat progressed. The S content did not increase by use of scrap. The temp and melting rate depended on the wt. of the metal charges. 1000 lb. charges were found best for the cupola used. The tensile strength of the product increased with the melting rate and temp. up to 1500°. The Si and C contents decreased as the percentage of steel scrap in the charge was increased; but the Mn content was const. A coke bed 24 in. above the tuyères gave the hottest and strongest Fe. The blast pressure should be controlled to give a rapid melting rate, with higher blast pressure the temp. of the product was higher, and the C content lower. Subsequent operation of the cupola was controlled in accordance with these findings, with excellent results; the strength of the Fe was increased 30% to 40,000 lbs. per sq. in., though keeping the hardness at 200 to 220 Brinell.

GEO. F. COMSTOCK

An analysis of the performance of fifty-four inch cupolas based upon records of practical operation. EDWARD E. MARBAKER. *Whiting Corp., Harvey, Ill. Am. Foundrymen's Assoc.* (preprint), No. 29-4, 71-90(1929).—The efficiency of foundry cupolas has not been given sufficient attention. The results reported were obtained through a questionnaire sent to 136 cupola operators to det. the conditions of practical operation. The ratio of heat evolved from the coke to that used in melting the Fe was studied separately for 8 cupolas with vertical, and 8 with inclined (boshed), 54-in. linings. In estg. the output, only the Fe discharged through the cupola spout was considered as melted. The use of a boshed lining decreased the melting rate to that of a cupola straight-lined to the min. diam. of the bosh. The amt. of coke used for the bed varied greatly. The true melting ratio is the wt. of Fe melted by 1 lb. of C, rather than coke. This ratio varied from 7 to 9.3, irrespective of whether the lining was straight or boshed. The sp. heat of gray Fe is higher when molten than when solid, and more heat must be applied per degree rise of temp. for superheating than for heating to the m p. The calcn. of thermal efficiency is described, taken as the total heat needed for melting and superheating, divided by the total heat supplied by complete combustion of the coke. Data for this detn. are easily secured. The thermal efficiencies from the author's data varied from 25.4 to 37.2%, the form of lining again having practically no effect, and were not closely related to the coke ratios. The blast vol. is very important to insure proper combustion but the data show that this varies greatly from an excess to a deficiency of air, with but small relation to the thermal efficiency. For a thermal efficiency of 35%, and a melting ratio of 8.4, a calcn. is given showing that 6000 cu. ft. of air per min. would be required. The boshed lining has some value in economy of bed-coke, keeping tuyères cleaner, and improving blast penetration.

GEO. F. COMSTOCK

The operation of Siemens-Martin furnace with coke-oven gas. G. BULLE. *Stahl u. Eisen* 48, 1353-62(1928); cf. *C. A.* 23, 1802.—Coke-oven gas gives good results, even with short preheating, due to its high heating value; on the other hand, the flame so obtained has a low heat cond. When overheated coke-oven gas is decomposed, C seps. and a gas rich in H and CO is formed, which has a higher heating value than the original gas, so that the preheating is not a disadvantage. Coke-oven gas is often used with throat gas as mixed gas, with throat gas and producer gas as tri-gas, also as an addn. to producer gas. All 3 types of mixed gases are used in Germany and are more economical than pure producer gas. Several works are using a so-called cold gas, that is, coke-

oven gas blown without any preheating, by means of water-cooled burners into hot air coming from the regenerators.

J. A. SZILARD

Trial of a forge furnace with metal recuperators heated by blast-furnace gas. A. LEMONNIER. *Chaleur ind.* 9, 463-4(1928).—The gas had CO 28, H₂ 3.7, CO₂ 10, O₂ 0.05, N₂ 58.3%, outside temp. 25°, pressure 735 mm., lower cal. value 850 cal./cu. m., external forge temp. 40°. Other necessary data are mentioned. The furnace was run at 1215° on steel ingots. Of 11,300 cal. supplied to the furnace, 2300 cal. were utilized. The yield is calcd. at 16%, the necessary tables and analyses being given in the test.

Improving of alloys and new aging phenomena in iron. G. MASING. *Arch. Eisenhüttenw.* 2, 185-96(1928).—A theoretical paper in which improving the mech. properties of duralumin and Be-Cu alloys is discussed in the light of the theory of dispersed supersatd. mixed crystals. The improvement of Fe-C alloys after quenching from over 650° is described.

J. BALOZIAN

Theory of the plasticity of metals. HIKOROKU SHOJI. Tohoku Imp. Univ. *J. Study of Metals* 5, 357-63(1928); cf. *C. A.* 20, 2808.—S. has previously shown that, when a metallic wire is stretched with a const. load by a very small amt. beyond its elastic limit, the velocity of elongation gradually approaches a definite value, and that the plasticity of metals may be compared by the magnitude of the final const. velocity. The present paper is a theoretical discussion of the same phenomenon, which was made under the assumption, that the act of unloading the wt. from the end of the wire, which had been stretched by a const. load, was equiv. to the act of pushing the wire up from below without taking off the wt., and that the law of the wire contracting with time is the same as in the case of elongation. The result shows that the velocity of elongation of the wire which is subject to a permanent deformation must approach a definite value. When a metallic wire of length l and the sectional area S is stretched by a load W which is greater than its elastic limit W_0 , the definite velocity v_B finally attained is given by the relation $v_B/l = pW/S$ or $p = v_B S/W$, where p is a const. relating to plasticity, $W_0/S = W_0$ is another const., which together with p characterizes the plasticity of metals. Experimentally the order of the metals arranged according to the magnitude of p is Cd, Zn, Pb, Sn, Ag, Al, Cu and that arranged according to the magnitude of W_0 is Cu, Al, Ag, Zn, Sn, Pb, Cd. With the rise of temp. p increases and W_0 decreases.

K. SOMEYA

Alloy cast irons. ARTHUR B. EVEREST. *Foundry Trade J.* 40, 45-8(1929).—A general theory of cast Fe is proposed, showing that the ultimate structure is detd. only by the relative stability of carbide and graphite (chem. compn.), and the thermal history. The manner of origin of the various forms of white, pearlitic, gray, etc., cast irons is described. The addn. of Si, Ni or Al favors graphite formation, while Cr, S and sometimes Mn and P increase the stability of the carbide. The forms of graphite and pearlite are also affected by alloy addns. The P should be low in high-duty cast Fe. For practical value an alloy addn. must not be too costly, and must mix easily with the Fe without bad effects. Al addns. produced graphitization up to 7%, but from 7 to 15% Al caused the formation of a hard, brittle carbide. With over 15%, the alloys were unstable. In small amts., 2 parts Al were required to give the effect of 1 part Si. No advantage of Al over Si was found, and Al made the castings dirty. Ni is easily used without loss or troubles from dirt, and favors graphitization mildly enough so that pro-eutectoid cementite is decomposed without interfering with pearlite. Uniformity of structure and hardness throughout castings of varying section is thus promoted by the replacement of some of the Si content by Ni. The lower-Si cast Fe is also more sound and dense, and the mech. properties are improved. Cast Fe with a soft ferritic matrix is not subject to much improvement from Ni. The addn. of Cr makes the carbide more stable, increasing the hardness, but the mech. properties of the Fe may be improved by small amts. of Cr, especially when the chilling effect of Cr is counteracted by Ni. The use of the alloys may be convenient and economical from a foundry viewpoint, as well as necessary to obtain superior mech. properties. A study of the changes

possible in a cast Fe by adjustment of the Ni, Si and Cr contents is illustrated by graphs. GEO. F. COMSTOCK.

Nickel and chromium alloyed cast iron. E. PIWOWARSKY. *Giesserei* 15, 1073-8 (1928).—A lecture. J. BALOZIAN.

Influence of nickel-chromium on cast iron. ARTHUR B. EVEREST AND D. HANSON, Univ. of Birmingham. *Foundry Trade J.* 40, 5-10(1929).—Cast irons were prepd. contg. from 0 to 0.75% Cr and from 0 to 3% Ni. These were investigated as to chill, hardness, fracture and microstructure. Cr increases and Ni decreases the tendency of Fe to chill. The influence of Cr is very powerful, only a small amt. is necessary to turn the Fe completely from gray to white. Ni reduces the hardness of the thin sections and increases that of the thick. Cr hardens all sections having a gray or a mottled fracture. The effect on white-Fe structures is in the same direction but not quite so regular. With 0.23 to 0.43% Cr, Ni exerts its normal effect but with higher Cr content (0.75%) the addition up to 3% of Ni did not render the Fe machinable. Cr causes a marked refining of the grains while Ni in general does not open up the grains. Increasing the Cr gives a progressively finer form of graphite, while Ni tends to coarsen it; but the result of Ni-Cr additions in the balance ratio produces a definite refining of the matrix. Cr alone produces massive carbide areas, which are eliminated by the addition of Ni. The authors conclude that "Ni will harden the gray portions of cast Fe and at the same time will eliminate its chilling tendency; Cr, on the other hand, increases the hardness of the Fe, but also increases its tendency to chill. Consequently, Ni and Cr may be added to cast Fe together in a ratio, so balanced as to have no effect on the depth of chill given by the Fe under certain circumstances, but in virtue of the combined effects of the alloy-elements on the structure of the Fe, a very marked refining of both the graphite and the pearlite is obtained with consequent increase in the hardness of the casting." For high-grade pearlitic Fe Cr added and Ni-to-Cr ratio, resp., should be: Less than 0.2%, 3 to 1; 0.2 to 0.3%, 4 to 1; 0.3 to 0.4%, 5 to 1. J. W. BOLCK.

Some theories of graphitization. H. A. SCHWARTZ. *Foundry* 56, 871-3, 908-20, *Am. Metal Market* 35, No. 216, 2nd Sect. 1-5, 29-30; *Foundry Trade J.* 39, 297-300(1928).—The formation of free C during freezing is called primary graphitization and that during a subsequent heat treatment is called secondary graphitization. Various theories on the formation of secondary graphite and the effect of other elements are discussed. J. W. BOLCK.

Photomicrography and metallography of graphite flakes. A. L. NORRIS AND L. W. BOLTON. *Bull. Brit. Cast Iron Research Assn.* 1928, No. 22, 52-4. The effects of variations in methods of polishing and photographing on the apparent size of graphite flakes in cast iron are discussed. Polishing often rounds off the edges of the metal bounding the plate, causing them to appear larger, while burnish polishing on the other hand tends to bridge over the flakes and in some cases completely obscures them. J. W. BOLCK.

Alloy cast iron. D. HANSON. Birmingham Univ. *Foundry Trade J.* 39, 319-21 (1928).—Using a Fe-C alloy of approx. 3.5% C and adding Si and Ni, the author concludes that the four main effects due to Ni are "(a) It hardens white iron (when the iron is of such a character that the cementite is stable); (b) it decomposes iron carbide, giving graphite; (c) it hardens the matrix, converting pearlite into sorbite or martensite; and (d) with high nickel, a soft austenitic gray iron is formed." A comparison of the effect of Si and Ni indicates that "above the critical range Ni and Si may be said to supplement one another, but below this range Ni restrains the action of Si in decomposing pearlite, and maintains a structure free from ferrite, while its own matrix hardening through sorbite formation is definitely in the opposite direction to the effect of Si." Ni is effective in reducing chill and eliminating hard spots. Ni up to 3% refines the graphitic structure but above this amount the structure may be coarsened. By reducing the Si and addn. of Ni the equalizing effect in the structure and hardness of castings of variable sections is pronounced. With Ni replacing Si in a ratio of two to one a marked improvement in the strength is obtained. J. W. BOLCK.

Effect of copper upon cast iron. ASHIO HOTARI. Kyushu Imp. Univ. *Bull. Coll. Eng. Kyushu Imp. Univ.* 3, 169-80(1928).—H. measured the tensile strength and the Brinell hardness of 9 kinds of cupriferous cast iron contg. 0.-1.7% Cu, 3.4% total C, and 1.5% S. Both the tensile strength and the Brinell hardness increase to a certain extent with the addn. of Cu, the rate of increase becoming slower in steels of high-Cu content and being linear in those of low-Cu content. Thermal analysis shows that the arrests on the cooling curves lie at different points. Microscopic examn. and chem. analysis show the increase of graphite with the increase of Cu, so that Cu accelerates graphitization. The corrosion test was made by dipping the samples in 5% HCl.

HNO₃, H₂SO₄, 2% NaCl and 9% NaOH soln. for 48 hrs. and measuring the resulting wt. decrease. The results show that Cu increases the resistivity toward acids markedly, the effect being max. at 0.25% Cu.

K. SOMEYA

Oxygen in steel. L. PERSOZ. *Aciers spec.* 3, 259-62(1928).—The effects of oxygen in crucible, elec. furnace, acid open-hearth, basic open-hearth, acid Bessemer and Thomas steels are discussed in detail.

A. J. MONACK

Gases extracted from iron-carbon alloys by vacuum melting. N. A. ZIEGLER. *Am. Inst. Mining Met. Eng., Tech. Publ.* No. 168, 3-15(1929).—Numerical data are given for gas evolution by vacuum melting for a series of lab. Fe-C alloys, ranging from 0.0038 to 4.45% C, as well as some com. steels and cast irons. CO is the principal constituent of the gaseous mixts. in all cases, the amt. increasing with the increase of C in the original sample. H is evolved to a small extent by the open-hearth sample, but not by the lab. samples or cast Fe. CO₂ is evolved in relatively small quantities in all the samples. H₂O vapor is given off in very small amts. by the low-C lab. alloys and the steels, but not by the high-C alloys and cast irons.

DOWNS SCHAAF

Two space models of equilibria in the system iron-carbon-oxygen. ERNST JANECKE. *Z. anorg. allgem. Chem.* 178, 73-96(1929).—Two new models are constructed to establish the factors which det. the equil. in the system Fe-C-O. In one the relation between temp. and compn. is given (without reference to pressure) in a 3-sided prism. The other, a right-angled prism, shows the relation between temp. and pressure with respect to the compn. of the gas phase at equil. For both figures the invariant and monovariant equil. are discussed in detail, particularly those (invariant) which occur at the temp. of the first formation of FeO from Fe₃O₄ and Fe (550°), and at the temp. of the appearance of martensite (740°). In the first case the phases involved are Fe, FeO, Fe₃O₄, gas and C or cementite (metastable). In the second case the phases in equil. are martensite, Fe, FeO, gas and C or cementite. The equil. with cementite is metastable and occurs at lower temp. (700°).

H. STOERTZ

The gamma-alpha transformation in pure iron. ALBERT SAUVEUR AND C. H. CHOU. *Am. Inst. Mining Met. Eng., Tech. Publ.* No. 169, 3-18(1929).—Polished samples of electrolytic Fe were heated in a vacuum, maintained in the gamma range for several hrs. and quenched in Hg. Photomicrographs show that the alpha phase is formed first along the crystallographic planes of the gamma phase and around the grain boundaries. The martensitic structure resulting from the drastic quenching is proved to penetrate to a substantial depth by repolishing and etching. With magnifications of 500 diam. the so-called Widmanstätten patterns are clearly seen and a close relationship is established between this structure and that of martensite. Also in *Heat Treating and Forging* 15, 305-6, 325(1929).

DOWNS SCHAAF

The influence of cold rolling and annealing at different temperatures on the tensile properties and structure of high-grade soft iron sheets. E. MARKE. *Vereinigten Stahlwerke, Hütten i. W. Archiv Eisenhüttenw.* 2, 177-84(1928).—The influence of cold rolling (under the critical range) to give 20-30% thickness decrease, and subsequent annealing (at 580°, 680°, 800°, 930°) on the tensile properties of soft Fe sheets is investigated. It is shown that increased cold rolling causes a strong decrease in the Erichsen no. and breaking strain, and an increase in the elastic limit, tensile strength and Brinell hardness. With increasing cold rolling there is distortion and extension of the crystallites. By heat treating, the effect of cold rolling on the structural and mech. changes is annulled. The change in the mech. properties is large on annealing at 580° and small between 680° and 930°, the greatest being in the breaking strain and the smallest in the Erichsen no. These properties are influenced considerably by annealing 2-3 hrs. instead of one, especially at 580°.

J. BALOZIAN

Axle housings of electric steel. ETHELBERT FAVARY. *Iron Age* 123, 477-8 (1929).—Shrinkage cracks in axle housings made from elec. steel contg. 0.30% C and 1% Ni were overcome (1) by rounding off and adding metal to the corners, (2) by the proper location of chills and (3) by soft cores and the addn. of longitudinal ribs.

DOWNS SCHAAF

The effect of the temperature of rolling on the quality of the rails. R. STUMPFER. *Stahl u. Eisen* 49, 177-87(1929).—Efforts to improve the quality of steel rails by changes in the chem. compn. of the steel, such as the increase of the C content from 0.65% to 0.80-0.88%, also by increased Si and Mn contents, the development of special V steel with 0.25-0.28% V and of Ti steel with 0.2% Ti, finally by heat treatment, are reviewed. The quality of the steel depends not only on the amts. of pearlite, ferrite, etc., present, but also on the form of these constituents. Three characteristic types of grain structures occurring in rail heads are shown (granular, network and overheated structures). The granular structure is transformed into network structure between 0.4 and 0.5% C; at

this point the curve of the tensile strength as a function of the C content shows a greater increase, that of the elongation a greater decrease, than below this point. A granular structure consisting of fine grains of pearlite, surrounded by a noncoherent network of ferrite, is the best. This structure can be obtained by a low C content with a correspondingly increased Mn content. Three series of rolling expts. were carried out, the temp. of the finishing rolling being 950, 1050 and 1015°, resp. Test pieces were taken from the rail head, the middle part and the base. The yield point, tensile strength, impact value and elongation were found to decrease with increasing finishing temp. The finishing temp. had no appreciable effect on the Brinnell hardness. At 950° the structure shows an intermediate stage between granular and network structure; at higher temps. the network structure prevails.

J. A. SZILARD

Heat treatment and testing of tools of high-speed steel. F. RAPATZ. *Stahl u. Eisen* 49, 250-5(1929).—The best grain structure can be obtained by hardening at 1280-1320°, followed by tempering at 550-600°. The high hardening temps. often cause burnt tool edges. This can be eliminated by the use of a bath of $\text{Na}_2\text{B}_4\text{O}_7$. A NaCl bath does not prevent decarburization. The only disadvantage of a $\text{Na}_2\text{B}_4\text{O}_7$ bath is its corrosive action. The tempering should be carried out after the hardened steel is cooled to 150°. The transformation of the rest of the austenite into martensite is rather slow; therefore, it is advisable to use a tempering period of 30 mins. to 1 hr., depending on the compn. of the steel and the size of the tools, followed by air cooling. For the testing of the tools Rockwell hardness, microscopic examn. and filing are used. The possibility of the use of physical methods, such as the testing of elec. and magnetic characteristics (cf. Styri C. A. 22, 2012), is discussed.

J. A. SZILARD

X-ray investigation of iron-zinc alloys. ATOMI ÔSAWA AND YOSHIKI OGAWA. Tohoku Imp. Univ. Sendai. *Z. Krist.* 68, 177-88(1928). (In English).—X-ray analysis was carried out for the complete Fe-Zn system. The crystal forms of several phases are similar to those of Ag-Zn, Au-Zn and Cu-Zn alloys. The crystal form of FeZn_{10} (considered FeZn_7 by previous investigators) is cubic, with $a = 8.93$ A. U. and 52 atoms in the unit cube. The space group is either T_d^3 , O_h^9 or O^1 . FeZn_7 has a close-packed hexagonal lattice, with $a = 2.788$ and $c = 4.481$ A. U. This unit contains 2 atoms. An elementary cell with the value for the a axis doubled would contain 8 atoms (7 Zn and 1 Fe). With Fe atoms at (000) in this larger unit, both Fe and Zn would have a hexagonal distribution.

L. S. RAMSDALL

Some properties of manganese steel. KAZUO MORIDERA. Yahata Steel Works. *J. Study of Steel Manuf.* 104, 274-80(1928).—M. measured the hardness of 2 kinds of Hadfield steel (contg. 1% C and 12% Mn) at the temp. range of 100-1000° with the samples quenched at 950°, and also the same subsequently annealed. No marked change of hardness is observed up to 600°. Above 700°, the steel is gradually softened. The samples which had been heated at 300-1250° were pressed 3 times with a steam hammer, to det. a suitable forging temp. Hardness was detd. on specimens air cooled from a temp. of 100-1000°. The specimen air-cooled from 600° was the hardest and it had a martensitic structure. Mech. properties of the water-quenched and quench-tempered specimens were also tested; it was found that the tensile strength, elongation and bending rate changes in a similar manner, while the hardness change is in opposite direction to them.

K. SOMEYA

Effect of copper upon the properties of steel. KENNOSUKE HAYASHI. *Bull. Ordnance* 6, 401-68(1928).—H carried out tensile tests on Ni-Cr steel contg. 0.04-3.05% Cu, Ni-steel and Cu steel at various temps. ranging between room temp. and 1100° with the following results: The influence of Cu cannot be recognized in the test made at ordinary temp. but the tensile strength decreases rapidly at a temp. above the A_1 point, red shortness being also apparent. At high temp., increase in Cu causes decrease in elongation. Mn steels contg. C 0.25, Si 0.2, Cu 0.3 and Mn 0.4-1.3% were annealed at 900°, and tensile tests made at ordinary temp. and at 600-1100°, together with tensile tests of welded material. At room temp. the tensile strength and the elastic limit increase while elongation decreases with increase of Cu. At high temp. red shortness increases with increase in Cu content; above 1% Cu, the material is difficult to forge. But in the Mn-contg. steel the red shortness caused by Cu is somewhat mitigated, the best result being obtained with 0.7-1% Mn for 1% Cu. The tensile strength tends to increase up to 800°. Above 800°, no change is apparent. No satisfactory result was obtained with the tensile test of welded material. Microscopic examn. shows that the structure of the annealed samples consists of ferrite and pearlite, the pearlitic structure becoming finer with the increase in the Cu content. The transformation point is lowered with the increase of Cu and Mn.

K. SOMEYA

Action of the principal addition elements in steel. L. PERSOZ. *Aciers spec.* 3, 249-55(1928); *Foundry Trade J.* 40, 181-2(1929).—P. discusses in detail the effects in steel of the following elements: N, P, As, S, Mn, Si, Cr, Ni, Cu, W, V, Mo, U, Co, Ti, Al, B and Ce. The amts. of each that should be present in steel are given as well as the effects of excess amts.

A. J. MONACK

Zirconium in steel. L. PERSOZ. *Aciers spec.* 3, 256-8(1928).—Zr added to steel acts simultaneously as a deoxidizer, denitrifier and desulfurizer. When sufficient Zr is added so that some remains in the steel the toughness and tenacity are increased, the best results being obtained when the Zr is equal to or less than 0.15%. The quality is much improved even when the finished steel contains only traces of Zr. Higher percentages than 0.15 tend to cause slag inclusions and favor segregation. In general, Zr should not exceed 0.35%; larger amts. cause steel to become brittle. Zr steels are suitable for making armor-plate. Tests show that nickel-chrome steel of 16 mm. thickness, nickel-molybdenum steel of 13 mm. thickness, and nickel-zirconium steel of 10 mm. thickness have equal resistance to the passage of rifle bullets. A typical Ni-Zr steel contains C, 0.40%; Mn, 1%; Si, 1.5%; Ni, 2%; Zr, 0.34%. Zr is added as ferro-zirconium with 30-35% Zr after the other addns. have been made. An appendix gives complete lab. directions for the detn. of Zr in steel as the phosphate and the detn. by means of phenylhydrazine.

A. J. MONACK

Studies in stainless steel. I. YOSHIHIRO KAWAKAMI. *J. Army Research Staff. Iron and Steel* 14, 838-951(1928).—K. took 20 kinds of Japan-made and 24 kinds of foreign-made stainless steels and classified them according to their chemical compn. into 8 kinds, viz. (1) steel contg. 11-17% Cr, (2) that contg. above 15% Cr, (3) steel contg. Cr and Ni as its chief constituents and contg. less than 5% of Ni, (4) the same contg. more than 5% of Ni, (5)-(8) those steels which contain Si, W, Cu and V as their chief constituent. In the dilatometric test of these samples with Honda's app. for thermal expansion measurement, no transformation was detected with the alloys contg. above 15% Ni. Magnetic analysis showed that those steels contg. above 5% Ni are paramagnetic and have an austenitic structure. With quenched specimens the hardness is the greatest when the C content is above 0.3%, the Cr content above 11% Cr, or in samples having less than 11% Cr and less than 4% W. When the samples whose structures have become martensitic on quenching are annealed, the hardness decreases gradually with annealing temp. up to 500°, while between 500° and 900°, the hardness decreases faster. With an annealing temp. of 1000°, max. hardness is obtained due to self-hardening. When the quenched sample has an austenitic structure, the hardness is little affected by tempering. For destroying the self-hardening property, annealing at 900° or 1050° gives the best results and the cooling velocity must be such that several hrs. are required before the sample passes through the transformation range. Density increases with increase of W, Cu and Ni content, and decreases with increase of Si and Cr. In comparing the acid-resisting property of the quenched specimens, the rusting which occurs on exposing them to atm. for 2 months, and also on keeping them in various acid solns., was detd. In the latter case the samples were kept for 1-15 days in a dil. soln. of NaCl, NaOH, HNO₃, H₂SO₄, HCl, AcOH, (C₂H₃)₃, citric acid, and in concd. solns. of HCl, H₂SO₄ and HNO₃ and in glycerol, and the wt. decrease was measured. When the heat-treated and untreated specimens were tested by this method, it was found that the resistance of the treated steel was always greater. When rolled, the corrosion was found to be greater in the direction of rolling than that perpendicular to it. It was also found that in the same kind of specimen the resistance decreases with increase in inclusions.

K. SOMEYA

Influence of various elements upon the nitrogenation of steel. TSUYOSHI NAKAYAMA. Tohoku Imp. Univ. *J. Study of Metals* 5, 413-27(1928).—N. first made reduced Fe consisting of small grains and studied nitrogenation in the NH₃ stream, measuring the wt. increase by means of a thermobalance. Although the relation between the quantity of combined N₂ and temp. was ascertained, the atm. oxidation of the sample could not be completely prevented. Next the sample was placed in a silica tube and was nitrogenated by passing NH₃ gas and heating. Since the wt. increase and the chem. analysis gave identical N₂ content, the former was taken to represent the degree of nitrogenation in all the subsequent studies of the velocity of nitrogenation at various temps. The velocity of nitrogenation is very small below 300°, increases rapidly above 400°, increasing more with the rise of temp. But the N₂ content measured after 1 hr. shows a max. at 450°, amounting to 10%. At about 600°, it suddenly decreases, becoming almost zero above 750°. When the Fe grain is large, the velocity of nitrogenation is small, and the temp. for obtaining the max. nitrogenation is a little higher than when Fe of small grain is used. To exam. the effect of various elements upon nitrogenation,

Fe-Al, Fe-Si, Fe-Ti, Fe-V, Fe-Cr, Fe-Mo, Fe-W, Fe-Mn, Fe-Co, Fe-Ni, Fe-Cu and Fe-C alloys of varying compns. were prep'd. and the velocity of nitrogenation was studied by passing NH_3 gas over the sample for 1 hr. at various temps. Elements that form stable nitrides (as Al, Si, Ti, Cr) accelerate nitrogenation, and the max. N_2 content attained in 1 hr. treatment is max. at 500° . With elements that form no stable nitride (as Cu, Ni, Co) the max. N_2 content is obtained at 600° . Mn forms a stable nitride and makes the N_2 content larger, showing a max. at 600° . When Al, Si, Ti, Cr, Mn, etc., are present a large amt. of N_2 is retained even when heated at a high temp. K. S.

A metallographic study of tungsten carbide alloys. J. L. GREGG AND C. W. KÜTTNER. Am. Inst. Mining Met. Eng., *Tech. Publication No. 184*, 3-12(1929). Four of five different com. W carbide alloys were found by means of x-ray diffraction patterns and microscopic examn. to consist of W_2C and WC; the fifth contained little if any W_2C , being composed almost entirely of WC. Alk. ferricyanide and a mixt. of concd. HNO_3 and HF were used as selective etching reagents; the alk. ferricyanide attacks WC and not W_2C ; the acid mixt. attacks W_2C and not WC. Also in *Heat Treating and Forging* 15, 317-20(1929).
DOWNS SCHAAP

High-strength brasses. O. W. ELLIS. Am. Inst. Mining Met. Eng., *Tech. Publication No. 167*, 3-25(1929).—As a result of an extensive investigation, the effects of Al, Fe, Mn and Sn upon the mech. properties of brass contg. in the neighborhood of 56.5% Cu are found to be cumulative. Hence, given the analysis of a complex brass and knowing the mech. properties of the basic alloy, and the effects of the elements present in the alloy other than Cu and Zn, the mech. properties of the mixt. in the chill-cast state can be estd.
DOWNS SCHAAP

Some observations in heat treatment of Muntz metal. L. RUSSELL VAN WERT. Am. Inst. Mining Met. Eng., *Tech. Publication No. 180*, 3-10(1929).—Photomicrographs of a quenched alloy of Muntz metal (60% Cu, 40% Zn) reheated to 750° show the general tendency of the alpha soln. to segregate along cleavage planes, and the mechanism whereby the pptd. alpha is taken back into soln. with rise in temp. Heating a quenched alloy results (1) in the breakdown of the metastable beta soln. and the ptn. of the solute preferentially in the cleavage planes of the beta and (2) when the temp. is raised sufficiently, in the re-resolution of this solute. An interesting feature of this re-resolution process is its peculiar mechanism, i. e., soln. occurs exclusively at the ends of the rectangular areas, the alpha "islands" remaining const. in width during the dissolving process and decrease in size takes place through reduction in length alone. Reheating brass quenched from 800° to the beta range and again quenching gives an abnormally large grain size.
DOWNS SCHAAP

Silver-copper eutectic. J. A. A. LEROUX AND E. RAUB. Schwabisch Gmünd. Z. anorg. allgem. Chem. 178, 257-71(1929).—Ag-Cu alloys are studied within the range 68-75% by wt. of Ag. Electrolytic Cu and 99.98% Ag are used; the melts are heated to 1200° and cooled at different rates. In series I they are quenched in H_2O at 2° , in series II they are cooled at a velocity of $2^\circ/\text{sec.}$, in series III at a velocity of 0.18/sec. and in series IV at 0.02-0.03/sec. Microscopic examn. is made on sections etched with dil. H_2SO_4 . The simultaneous occurrence of primary Ag- and Cu-rich mixed crystals is found to be connected neither with undercooling nor with a sepn. of the melt, but is rather explained by the greater tendency toward crystn. of the Cu-rich mixed crystals. Eutectic crystn. is attained by a smaller time difference between the sepn. of the 2 types of crystals. Melts of Ag-rich mixed crystals show a strong tendency to undercooling, while Cu-rich crystals exhibit this tendency to a very limited extent. With increasing undercooling of eutectic melts the tendency toward crystn. becomes greater for the Ag-rich than for the Cu-rich constituents. The detn. of the eutectic concn. microscopically is therefore impossible, nor is thermal or chem. analysis free of objection, because of the non-uniformity in the distribution of the primary sepn. In most cases the eutectic colonies are identical with the grain, but in others several eutectic colonies form one crystal. The form of the colonies always det. the form of the crystal grain. Variation in the form of eutectic colonies is attributed to the strong tendency to directional growth of Cu-rich mixed crystals. The entire crystn. process of the eutectic melt appears to be detd. by the dominant properties of the Cu-rich mixed crystals. Photomicrographs are shown.

Structure of some ternary alloys of copper, zinc and aluminum. A. J. BRADLEY AND C. H. GREGORY. Mem. Proc. Manchester Lit. Phil. Soc. 72, 91-100(1927) 81.—In metallic alloys if the proportions of the ingredients are other than what is required to give an ideal intermetallic compd., the term "solid soln. in an intermetallic compd."

has been used, but the authors prefer "complex solid soln." Three ternary alloys of Cu, Zn and Al were made up from binary alloys of Cu and Zn with the γ type of structure and alloys of Cu and Al with the analogous γ' structure, mixed in the ratios 3:1, 1:1, 1:3. They were found by the x-ray powder method with a tube of the hot-filament type to consist of homogeneous solid solns. with the same type of structure as the binary alloys. The structure in each case is a complex cubic arrangement contg. 52 atoms per unit cell, the lattice dimensions showing a continuous decrease as the Cu + Al content increases. The similarity of these alloys appears to be related to the fact that in each case the concn. of valency electrons is approx. the same. H. STOERTZ

Beryllium and its alloys. A. VALIANE. *Aciers spec.* 3, 240-8(1928).—V. has presented a very complete and detailed review of the subject. The following are discussed: Be-contg. minerals; prepn. of Be by electrolytic and other methods; properties of Be; Al-Be, Be-Ni, Co-Be, Fe-Be alloys—their properties and equil. diagrams. In conclusion, V. states that it is still necessary to rep. alloys of a d. of 4 to 5. A bibliography is appended. A. J. MONACK

Aluminum-silicon alloys: their properties and some applications. II. R. B. DEELEY. *Foundry Trade J.* 40, 87-90(1929); cf. *C. A.* 23, 1857.—Fifteen photographs show the replacement of parts made of wood, pressed steel and malleable castings by Al-Si alloys. DOWNS SCHAAF

Effect of arsenic on dispersion-hardenable lead-antimony alloys. K. S. SELJESATER. *Am. Inst. Mining Met. Eng., Tech. Publication No.* 179, 3-10(1929).—Micro-Brinell hardness figures were obtained for Pb-Sb alloys contg. from 1 to 4% of Sb and from 0 to 1% As for various lengths of time and temp. of aging. The elec. conductivities of Pb-As alloys contg. from 0 to 2.15% As were measured at 25° and 100°. The tensile strength was measured on the same alloys used in the cond. measurements after quenching from 282° and aging at various temps. An explanation is offered for the effect of As on dispersion-hardenable Pb-Sb alloys. DOWNS SCHAAF

An open-flame stationary hearth-type furnace for melting aluminum and its alloys. ROBERT J. ANDERSON, GEORGE E. HUGHES AND MARSHALL B. ANDERSON. Fairmont Mfg. Co., Fairmont, W. Va. *Am. Foundrymen's Assoc.* (preprint) No. 29-6, 153-62 (1929).—Furnaces larger than the usual Fe-pot type are useful in melting Al alloys in large quantities, because of the large-sized casting scrap to be remelted. An open-flame furnace lined with fire brick, suitable for this purpose in sizes from 2000 to 50,000 lbs. capacity, is described. Insulated walls, hearth and roof, and cross-firing by having the burners and stack at the same end of the furnace are recommended to secure fuel economy. A fuel efficiency of 24.75% was obtained, with a melting cost of \$1.48 per ton. GEO. F. COMSTOCK

Non-ferrous casting alloys. WESLEY LAMBERT. *Foundry Trade J.* 39, 345-6 (1928).—A brief description of the compn. and phys. properties of Admiralty gun metal, phosphor bronze and aluminum bronze. Compounding and casting procedure is touched upon. J. W. BOECK

Correlation of laboratory corrosion tests with service: Weather exposure tests of sheet duralumin. HENRY S. RAWDON. *Am. Inst. Mining Met. Eng., Tech. Publication No.* 173, 3-24(1929).—R. compares lab. and weather exposure tests on sheet duralumin. A close parallelism was found between service and lab. tests proving the value of lab. tests in estg. performance in service. Corrosion is intercryst. in most cases. Chloride solns. are the most potent halogens causing this kind of attack. Rate of attack is accelerated by temp. Cold working increases susceptibility to intercryst. attack. Anodic oxide films afford protection only when well greased. Coatings of varnish and bituminous coatings fail rapidly. Al pigmented rubber coatings give excellent performance in lab. tests. Al spray coatings give excellent results. B. E. ROETHLI

Corrosion—an apparent relation of protective film to microstructure. CHARLES VAN BRUNT. *Ind. Eng. Chem.* 21, 352(1929).—The corrosion of teeth in a gear pump was most pronounced at the site of greatest relative movement between parts, indicating that the protective film had been sheared or rubbed off. It is believed that the segregation of impurities along grain boundaries causes a weakening of the structure of the rust film on cast iron and that with resistant alloys the segregated matter forms a very resistant deposit. B. E. ROETHLI

Some aspects of corrosion fatigue. T. S. FULLER. *Am. Inst. Mining Met. Eng.,*

Tech. Publication No. 172, 3-8(1929).—Steel samples exposed to conditions permitting the absorption of H prior to fatigue testing all showed a decrease in the no. of cycles necessary to fracture. Conclusion: in corroding media (10% H_2SO_4 or strong NaOH) permitting the absorption of H this factor lowers the fatigue strength while in other media pitting is the prime cause. Zn-coated specimens fail sooner than Sn-coated ones probably because of the brittle character of the bond between the steel and the Zn coating. B. E. ROETHELI

Corrosion of tin and its alloys. C. L. MANTELL. *Am. Inst. Mining Met. Eng., Tech. Publication, No. 171, 3-38(1929).*—An excellent review on the corrosion of Sn covering chem. properties; phys. corrosion (tin pest); chem. corrosion by inorg. acids, org. acids, bases, salts, halogens, S, org. compds. and food products. A summary of the corrosion and corrosion-resistant properties is given of binary alloys of Sn with Al, As, Ba, Hg, Cd, Ce, Cu, Au, Fe, Pb, Mg, Pt, K, Ag, Na and Si. B. E. ROETHELI

Acid handling in a metal finishing plant. PERCY C. KINGSBURY. *Metal Ind. (N. Y.) 27, 23-4, 78-9(1929).*—A description of the metal-pickling plant of the Siemens-Schuckert-Werke, Siemenstadt, Germany, based upon an article by Paul H. Perl in *Werkstattstechnik*. A sep. building is provided for acid storage and mixing, the acid is dumped into a storage vessel outside the building, elevated by compressed air to 254 gals. storage vessels on the ground floor, and then elevated by the same means to the rooms where needed. Ample vents and exhaust fans carry off fumes. W. C. E.

Oxygen and metals—some features in their relationship. F. JOHNSON. *Foundry Trade J. 39, 279-80(1928).*—The effect of O on corrosion, i. e., differential aeration, passivity and protective character of oxide films, is discussed. Oxidation at high temps. and in melting metals is also discussed. The detrimental effect of O in Cu to be rolled into sheets is pointed out. The subject of deoxidation of molten metals is treated briefly. J. W. BOECK

The practical rapid testing of rust-free steel. V. DUFFEK. *Chem. tech. Reichsanstalt, Berlin. Korrosion 4, 9(1929).*—Tests made by D.'s method (C. A. 21, 2454) are illustrated. J. H. MOORE

Electrochemical behavior of chromium steels and tendency to rust. OSCAR MEYER and KARL ROESCH. *Arch. Eisenhüttenw. 2, 119-25(1928)*—The electrochem. behavior of Cr steels, and the relation between the tendency to rust and the single potentials in aq. solns. of 1/1 N- KNO_3 , NH_4NO_3 (1:1), 0.5 molar $KCrO_4$, $CrSO_4$, cold standard K_2SO_4 , 1/1 N-KCl, sublimate soln. (1:1000), dil. HNO_3 (1:10), dil. H_2SO_4 (1:50), AcOH (4.5%), 1/1 N- $FeSO_4$ and in cond. H_2O are investigated, time-potential curves being obtained. Except in special cases, rusting of the Cr steels commences in the aq. solns. of the salts at $e_H < -0.015$ to -0.010 v. In the HNO_3 soln., after 45 hrs. the easily dissolved specimens show a higher potential than those which were more resistant. In the $FeSO_4$ soln. the rusting is found to be a function of the C content of the steel. The surface conditions of the steels exert a large influence on the potential values and the rusting. In general, the time-potential curves of the specimens treated with emery approach those of the polished specimens. The p. ds. produced at the various surfaces are greater with the hardened than with the forged or annealed materials. J. BALOZIAN

Apparatus for separating and cleaning ores, etc. REMBRANDT PEALE, WILLIAM S. DAVIES and WILLIAM S. WALLACE. Fr. 646,313, Dec. 12, 1927.

Treating ores with nitrates or nitric acid. S. C. SMITH. Brit. 295,224, April 5, 1927. Ores, concentrates, residues, etc., are treated with HNO_3 (or metal sulfate solns. obtained from ores, etc., are treated with $\text{Ca}(\text{NO}_3)_2$) to obtain the metals in soln. as nitrates from which the metal values may be recovered and HNO_3 or $\text{Ca}(\text{NO}_3)_2$ regenerated. When HNO_3 is used, the metals may be completely or fractionally pptd. by addition of CaO , $\text{Ca}(\text{OH})_2$ or CaCO_3 and the $\text{Ca}(\text{NO}_3)_2$ soln. thus formed treated with an acid such as H_2SO_4 to ppt. a Ca salt and regenerate HNO_3 or treated to obtain the $\text{Ca}(\text{NO}_3)_2$ for use as fertilizer. Various examples are given, including treatments of Pb Zn fume, a sulfate liquor contg. Cu and Zn and an oxidized Pb Zn ore. Mention is also made of applying a similar process to the *obtainment of pure MgO* from a mixt. of MgCO_3 and CaCO_3 .

Treating ores or the like containing lead and zinc. WILLIAM H. CORBOULD. U. S. 1,706,143, March 19. See Brit. 273,420 (C. A. 22, 2036).

Reducing ores. T. ROWLANDS. Brit. 295,338, Feb. 10, 1927. Ores or the like are heated with solid C or partly devolatilized coal and with reducing gases obtained by the low-temp. carbonization of coal or like material, the gases being treated to convert at least a large proportion of the CO_2 into CO and the low-temp. carbonization being effected by heat from the reduced ore and gases obtained at various stages of the process. An app. is described.

Reducing ores. PAUL GREDT. Ger. 471,271, Sept. 10, 1925. In reducing fine ores, particularly oolitic ores and slimes obtained from minette, a furnace of known kind is used, but the velocity with which the ore is conveyed through the furnace and

the temp. of the reducing gases supplied thereto are regulated in accordance with temp. measurements at various parts of the furnace.

Desulfurizing ores. DÉSIRÉ J. P. DELVILLE. Fr. 646,883, Jan. 9, 1928. Ores are desulfurized by roasting in a closed space, a gas contg. O and SO₂ being passed through so as to obtain a gas contg. sufficient SO₂ to produce H₂SO₄ economically.

Concentrating copper ores. JAMES A. HOLLADAY (to Union Carbide Sales Co.). U. S. 1,706,293, March 19. Oxidized Cu minerals are prep'd. for froth flotation by suspending the finely ground mineral in water as a pulp, treating with C₂H₂ and preventing aeration of the pulp during the process by displacing air with a noncombustible inert gas such as N so that the action of the C₂H₂ on the mineral particles is intensified.

Smelting tin-bearing tungsten ores. FREDERICK M. BECKETT and WILLIAM C. READ (to Electro Metallurgical Co.). U. S. 1,705,655, March 19. The ore is treated with a Cl comp'd. such as S chloride and the mixt. is then heated by an exothermic reaction between the ore and Si, to a temp. suitable for the formation and volatilization of Sn chloride.

Iron ore briquets, etc. K. GRÖPPEL, E. GRÖPPEL and A. WASCHKAU (trading as Maschinenfabrik F. Gröppel C. Lührig's Nachfolger) and C. P. DEBUCH. Brit. 295,910, March 2, 1928. Granular Fe ore or other Fe-bearing material such as blast-furnace dust is heated in a rotary oven and then while in a plastic condition is passed between cooled molding rollers (of an app. which is described).

Melting pot for magnesium or other light metals and alloys. JOHN E. HOY (to Dow Chemical Co.). U. S. 1,707,161, March 26. Structural features.

Melting stereotype metal, etc. MASCHINENFABRIK AUGSBURG-NÜRNBERG A.-G. Brit. 296,086, Aug. 26, 1927. Melting pots are heated by the satd. vapor of a liquid, the b. p. of which is near the casting temp. of the metal and the pressure of which is only a few atm. at the casting temp. Satd. CaCl₂ soln., tetraline, aniline, naphthalene, paraffin or Hg may be used. Structural details of double-walled melting pots are described.

Mixing apparatus suitable for use in treating molten lead with sulfur for refining, etc. HERBERT W. YORK (to American Smelting and Refining Co.). U. S. 1,706,722, March 26.

Treating molds for producing soft castings of ferrous metals. HUBERT A. MYERS (to Metal Castings Holding Co.). U. S. 1,706,858, March 26. The matrix of a mold, which may be formed from iron or an Fe alloy, is coated with a material contg. a CN salt, such as NaCN or KCN and the mold and coating are heated to liberate C from the CN salt. The cyanide may be mixed with plumbago or MgO.

Casting metal ropes, etc. EMIL HAMMERSCHMID. Ger. 471,492, Nov. 7, 1926. Addn. to 460,873. Ger. 460,873 describes app. for casting metal ropes, etc., in which the metal flows into a rotating channel. This is now modified by providing a stationary channel while moving the means for pouring the metal, and (or) by shaking the channel during the casting.

Increasing the density of cast metal. N. N. YAROTZKII. Russ. 5357, May 31, 1928. The d. is increased by giving a rotating motion to the molten metal and subjecting it simultaneously to a pressure of gases.

Treating sand for molding. GILBERT MICHEL. Ger. 471,461, Oct. 15, 1924. Molds for casting easily oxidized metals, e. g. Mg, are prep'd. from sand which has been pretreated by thorough incorporation with a mobile soln. of a resin in an oil.

Apparatus (with an adjustment to fix the time of treatment) for mixing and mulling foundry sand, etc. JOSEPH T. SIMPSON. U. S. 1,706,417, March 26. Structural features.

Oil burner for metallurgical furnace. SOC. TUBALCAIN. Fr. 646,068, Dec. 22, 1927.

Vertical retort furnace for treating ores, etc. F. L. WILDER, E. MORRIS, E. SCHIFF and E. S. KING. Brit. 295,226, April 6, 1927. A furnace suitable for roasting ores, sulfides, arsenides, etc., comprises a vertical retort surrounded by an annular heating chamber heated by producer gas, and successively surrounded further by an annular air passage (through which air for combustion is introduced) and an annular flue. Various structural details are described.

Rotating furnace for roasting sulfur ores and the like. METALLBANK and METALLURGISCHE GESELLSCHAFT A.-G. Fr. 646,881, Jan. 9, 1928. The furnace is divided into compartments by vertical partitions with openings, the partitions having projections or ribs between which the ore flows and which direct the ore to the opening into the next compartment.

Cupola furnace forehearth. CARL REHN. Ger. 471,460, Feb. 26, 1927. Addn.

to 402,438. The forehearth has a partition and the arrangement is such that the molten Fe from the furnace fills both compartments of the forehearth simultaneously.

Heat-treating furnace (cooled rim on cyanide pots). CRANSTON H. CARPENTER and ALVIN D. KEENE (to Westinghouse Elec. & Mfg. Co.). U. S. 1,705,714, March 19. A flange and cooling pipe is arranged to cool the rim of a crucible or cyanide pot used for heat-treating, in order to effect solidification of molten material creeping out of the crucible.

Furnace for heat-treating metal articles. THOMAS J. LAURENCE (to Chrysler Corp.). U. S. 1,705,621, March 19.

Furnace (with a continuous track) for bright annealing of balls for bearings, etc. JOHN F. BAKER (to Westinghouse Elec. & Mfg. Co.). U. S. 1,705,703, March 19.

Furnace with an annular heat-treatment chamber for heat-treating and quenching. JOHN F. BAKER (to Westinghouse Elec. & Mfg. Co.). U. S. 1,705,704, March 19. Structural features.

Recuperative furnace for annealing or similar heat treatments of wire in bundles, etc. JOHANN SCHNEPF (to Westinghouse Elec. & Mfg. Co.). U. S. 1,705,686, March 19. Structural features.

Regenerative welding furnace with two separately heated hearths. JULIUS BERTRAM. Ger. 471,478, Nov. 15, 1923.

Charging blast furnaces with compressed coal. OTTO VOM BOVERT. Fr. 646,734, Jan. 6, 1928.

Cast iron. EUGEN PIWOWARSKY (to Edeltgussverband G. m. b. H.). U. S. 1,705,995, March 19. Molten iron is heated above that temp. above which the formation of carbide will decrease while the formation of graphite will increase (this temp. being substantially higher than that of solidification, and suitably about 1400°).

Gray cast iron. HEINRICH HANEMANN (to Edeltgussverband G. m. b. H.). U. S. 1,705,972, March 19. In order to destroy the graphite nuclei in the metal, it is heated to 1250–1300° and this temp. is maintained for a few hrs. before casting until a substantially uniform distribution of finely divided nonlamellar graphite is effected throughout the metal.

Wrought iron containing nickel. INTERNATIONAL NICKEL CO. Brit. 295,857, Oct. 11, 1927. Wrought iron is prepd. with a C content of not more than 0.08% and Ni 0.25–5.0% and may contain "up to 1% or even 2%" of Cu, Cr and Mo. The presence of Ni 2% increases the tensile strength of the wrought iron 20%. Various details of procedure for prepg. wrought-iron alloys of this character are given.

Iron and steel. H. J. VAN ROYEN. Brit. 295,315, Aug. 9, 1927. Iron or steel suitable for use in the process described in Brit. 285,814 (C. A. 23, 87) is obtained by blowing through the molten metal (suitably under a new slag) a reducing noncarburizing gas which does not increase in volume on oxidation such as a mixt. of CO, CO₂ and N.

Carburizing iron and steel. ROBERT G. GUTHRIE and OSCAR J. WOZASEK (to Peoples Gas By-Products Corp.). U. S. 1,706,356, March 19. Iron or steel while heated and maintained at an elevated temp. in a container or retort is treated with a carbonaceous gas such as "town gas" and at the beginning of this treatment is also treated with a minute quantity of O to form an oxide catalyst so that the rapidity of penetration of the C into the iron or steel during the carburizing is increased.

Heating of steel. VEREINIGTE STAHLWERKE A.-G. Fr. 646,119, Dec. 23, 1927. Carburizing and superficial decarburizing of steel when heated to incandescence is prevented by using an atm. consisting of a mixt. of carburizing gases such as CO or CH₄ with decarburizing gases such as H, blast-furnace gas or N.

Chromium steel. ALEXANDER L. FEILD. Fr. 646,008, Dec. 17, 1927. Stainless steels contg. about 12–18% Cr and little C are made by incorporating ferrochrome contg. a high amt. of C in a Fe bath and C is eliminated by iron ore or scale, Cr also passing into the slag. The Cr is reduced from the slag by the addn. of a noncarbonaceous reducing agent, e. g., Fe-Si, and a base such as lime; it then passes into the bath. The content of Cr may be finally adjusted by the addn. of Fe or ferrochrome. Other alloying elements such as Ni, Cu, Mo or V may be added.

Semi-steel castings. J. ROBINSON. Brit. 296,080, Aug. 25, 1927. A mingled charge of molten cast iron and steel (such as that used for chill rolls and ingot molds) is intimately mixed by the reaction of aluminothermic material (such as 1% of aluminothermic reaction metal together with BaO₂) which is added to the charge.

Alloy. A. GUDZ. Swiss 127,824, Feb. 15, 1927. An alloy contg. Cu, Cr, Ni and Mg is prepd. by melting the metals together with the usual layer of KF, to form an intermediate alloy, in such percentages as to give the desired properties. A small amt.

of Mg is added. Thus, 50% Al, 25% Cu, 12½% Cr and 12½% Ni are melted together and a layer of powd. KF added. About 1% Mg is then added.

Alloys. SIEMENS & HALSKE A.-G. Brit. 295,971, May 21, 1927. Heavy metals such as Ni, Co and Pb or their alloys and Cu-P or Cu-Ni alloys contg. at least 10% Ni (but excluding Fe-Cu, Ag and Cu-Ni alloys contg. less than 10% Ni) are improved by alloying with 0.1-15% of Be. Mg, Sn, Zn, Sb, Al, Cd, C or Si may also be added. Various details of heat treatment of the alloys are given and they may be used for the manuf. of springs, for parts subjected to frictional stresses of elec. app., etc.

Alloys for bearings. ELECTROLYTIC ZINC CO. OF AUSTRALASIA, LTD. Brit. 295,991, Aug. 22, 1927. Alloys are formed of Cu 95-97 and Cd 3-5 parts, with or without addn. of up to 0.5% Mg. Rosin may be used as a flux in making the alloys. Cf. C. A. 23, 88.

Brazing alloy. ROBERT T. GILLETTE (to General Electric Co.). U. S. 1,706,154, March 19. An alloy is formed mainly of Cu and contains also Sn about 8% and Ag 8%. It has a m. p. of about 925°, and is suitable for brazing Cu to cast iron.

Alloy for use in telephone receivers. STANDARD TELEPHONES & CABLES, LTD., and S. T. BUER. Brit. 295,668, May 17, 1927. Pole pieces are formed of an alloy of Ni and Fe, or of Ni, Fe and Cr and are welded to the permanent magnet.

Magnetic alloys. W. S. SMITH, H. J. GARNETT and J. A. HOLDEN. Brit. 295,443, May 13, 1927. Iron alloys are formed contg. not more than 0.05% C and contg. Si 1-10 and Cr 1-10% (the Si content being, preferably, 3-5 times the Cr content). A deoxidizer such as Al may be used.

Magnetic alloys. W. S. SMITH, H. J. GARNETT and J. A. HOLDEN. Brit. 296,137, April 30, 1927. Alloys of high permeability suitable for loading telephone conductors contain Cr 1-10, Al 1-4% and the balance Fe. Mo may be used wholly or partly to replace the Cr and up to 1% of Mn or Si or both may also be added. The alloys may be made from iron contg. 0.04% C and may be heat treated to develop high magnetic permeability as by passing through a tube furnace at a temp. of 900° or may be annealed at 1020°.

Magnetic material. ISAAC F. KINNARD (to General Electric Co.). U. S. 1,706,172, March 19. A magnetic material having a temp. permeability characteristic which approaches unity at about 100° and which increases substantially uniformly with decrease in temp. below about 100° over a wide range of temp. contains Cu 40-20 and Ni 60-80 parts and a small quantity of Fe. U. S. 1,706,171 relates to temp. compensation of magnets such as those of an induction type watt-hour meter.

Aluminum alloys for bearing metals. T. GOLDSCHMIDT A.-G. Brit. 295,265, Feb. 25, 1926. Al is first treated with one or more of the metals Ca, Ba, Sr and Be, and afterward with one or more of the metals Ti, V, Mo, W, Cr, Fe and Mn or with B. Among the other materials which may be present are: Mg, Zn, Cu, Ce, Li silicide, Mg silicide, Si, Co and Ni.

Copper alloys. C. BILLINGTON. Brit. 295,769, May 25, 1927. Alloys of Cu are formed contg. also 7-28% Mn and either 2-9% Al or 2-9% Al and 2-8% Zn, or 3-20% Pb and 2-8% Zn. Up to 1% of Cr, Ni, V, Mo or Fe may also be added.

Alloys of lead with alkaline earth metals. GUILLAUME J. KROLL. U. S. 1,707,059, March 26. Lead is heated at a reacting temp. (not exceeding 1100°) with alk. earth metal carbides such as CaC₂ in the absence of any substance such as would form a protective layer around the carbide impenetrable by Pb.

Tungsten alloys low in tin and arsenic. FREDERICK M. BECKET (to Electro Metallurgical Co.). U. S. 1,706,344, March 19. Ores of W contaminated with Sn and As are reduced and Si is alloyed with the W as it is reduced to produce an alloy contg. at least 10% Si; most of the Si is then oxidized with a metal oxide such as W oxide in which the ratio of the total reducible metals to the total Sn and As is higher than in the ore first reduced.

Alloy screens in internal-combustion engine construction. R. W. BAILEY AND METROPOLITAN-VICKERS ELECTRICAL CO., LTD. Brit. 295,303, May 4, 1927. Screens which may be made of alloys of Ni and Cr or of ferrous metals contg. addns. of Ni, Cr or W, and which may be perforated or slotted, are attached to pistons, valve faces or cylinder walls of internal-combustion engines to reduce the transfer of heat from the combustion chamber. Various structural details are described.

Dissolving difficultly corrodible alloys. THEODOR KIRTL. Ger. 471,281, July 15, 1927. Alloys which normally resist attack by acids and anodic attack, e. g., alloys rich in Sn, Cu, and Sb, are rendered susceptible to attack by alloying them with "light elements," e. g., Na, Ca, P or Si. Waste of such alloys may be thus worked up.

Heat-resistant metal articles. WILLIAM E. RUDER (to General Electric Co.).

U. S. 1,706,130, March 19. Articles such as wires are formed mainly of iron with a surface layer alloyed with Al to form a heat-resisting coating and an interior portion substantially free from Al and contg. a material such as Cr or Ni to prevent penetration of the Al into the interior of the metal when the article is exposed to high temps. Cf. C. A. 22, 1130.

Heat treatment of steel railway rails. EDWARD F. KENNEY (to Bethlehem Steel Co.). U. S. reissue 17,240, March 19. See original pat. No. 1,619,025 (C. A. 21, 1247).

Hardening the heads of steel rails, etc., by water sprays. VEREINIGTE STAHLWERKE A.-G. Brit. 295,986, Aug. 22, 1927. Various mech. features and an app. are described.

Receptacle for holding metal articles during carburizing. WILLIAM J. MERTEN (to Westinghouse Elec. & Mfg. Co.). U. S. 1,705,674, March 19. Structural features.

Apparatus for pickling metal articles. HARRY F. WAHR. U. S. 1,706,718, March 26.

Ornamental effects on metal surfaces. K. BARANOWSKI. Brit. 295,889, Dec. 21, 1927. Metal articles are pickled, placed in an electrolytic bath to produce a granular surface and subjected to the action of a flame directly on removal from the bath or after coating with solns. such as NaOH soln. or with pastes made from salts such as AgNO_3 . A protective coating of enamel or varnish may be applied. The bath used may be formed from iron, brass, Ag or Cu but preferably is a 24° Bé. CuSO_4 soln. A voltage of 1-2 increasing to 10 volts may be used. Preferably, the article is preliminarily coated with Cu, and varnish resist designs may be applied to produce inlaid effects.

Increasing the elastic limit of metal rods, tubes, etc. G. KERÉKGYARTO. Brit. 295,390, Aug. 11, 1927. Various articles, especially those formed of wrought iron, have their elastic limit increased by applying torsional stress to cause permanent set and then removing the stress. The metal may be heated during twisting and further worked after the treatment. Rods, tubes, gun barrels, and shafts or airplanes or automobiles may be subjected to the treatment.

Copper tubing with highly flexible deeply corrugated walls. FRANK L. O. WADSWORTH (to Fulton Sylphon Co.). U. S. 1,706,198, March 19. Relatively deep and narrow corrugations are formed in a thin-walled tube, and the deeply corrugated wall is heated to 230-400° for about 1-5 hrs. in order to develop a high degree of elasticity.

Coating metals. SIMON B. WEINMANN. Ger. 470,118, June 7, 1925. A coating for metals contains aldehydes. A suitable mixt. contains water, polishing material such as siliceous chalk, NH_4OH , olein and aldehyde.

Coating metal bands, wires, etc. SPEZIALFABRIK FÜR ALUMINIUM-SPULEN UND LEITUNGEN G. m. b. H. Fr. 646,374, Dec. 27, 1927. Metal bands, etc., to be coated are passed through an electrolytic pptn. or other bath in a circuitous path over rollers so that the band becomes bent in different directions and the coating becomes elastic. Cf. C. A. 23, 370.

Apparatus for coating tubes, pipes, etc., with zinc by submerging in a zinc bath. GOTTFRIED BUCHERT. U. S. 1,706,348, March 19.

Protecting metals. COMPAGNIE FRANÇAISE POUR L'EXPLOITATION DES PROCÉDÉS THOMSON-HOUSTON. Fr. 645,990, Dec. 21, 1927. Metals are protected against corrosion by covering the surface with a mixt. of powd. Zn and a volatile binder having a basis of cellulose or nitrocellulose such as pyroxylin. An example contains Zn powder 454 g., soln. of pyroxylin 72, C_2H_5 36, AcOAm 18 cc. The mixt. may be projected with a pulverizing pistol De Vilbiss, type D.

Removing rust. I. G. FARBENIND. A.-G. (Carl Immerheiser, inventor). Ger. 471,172, Mar. 2, 1926. The affected objects are treated with sulfonation products of anthracene residues or of crude anthracene, alone or mixed with minor amts. of other org. or mineral acids and (or) with oils or fats.

Deoxidizing copper. SIEMENS & HALSKE A.-G. (Georg Masing, inventor). Ger. 571,209, Nov. 28, 1926. Li is used to deoxidize Cu. It may be added to the Cu before or during smelting, suitably as a Cu-Li or Zn-Li alloy. An addn. of less than 0.2% is sufficient. The deoxidized product has a higher sp. gr. and cond. than Cu.

Cuprous oxide on copper. HANOVIA CHEM. & MANUF. CO. Fr. 646,408, Dec. 27, 1927. Cryst. Cu_2O is obtained on Cu surfaces by placing the Cu in a furnace, reducing the partial pressure of the O and heating to within less than 58° of the f. p., increasing the partial pressure of O until the required thickness of Cu_2O is obtained without formation of CuO . The partial pressure is again reduced and the furnace cooled. As elec. currents pass easily from the Cu_2O to the Cu but not as easily from the Cu to the Cu_2O , the process is of value in the manuf. of elec. rectifiers. Fr. 646,409 describes a process

whereby a good elec. contact is obtained between Cu_2O and Cu by obtaining chemically or electrolytically a fine deposit of Cu or Ni on the Cu_2O .

Separating platinum. ÉTABLISSEMENT MÉTALLURGIQUE DE VIENNE and GEORGES A. L. R. COLLARD. Ger. 471,208, Feb. 11, 1927. The method of sepg. Pt from another noble metal in which the mixt. is fused with PbO and a S compd., the noble metals collecting in the Pb bath so obtained, is modified by adding to the bath at least 1% Cu calcd. on the Pb. The Cu sepg. on the surface carries with it the Pt and a little Au and Ag, while the Pb is free from Pt and rich in Au and Ag. The Pt-stanniferous layer may then be further refined by fusion with Pb free from Cu. The treatment is especially suitable for jewellers' filings, ashes, waste, etc.

Tin. E. A. ASHCROFT. Brit. 295,805, July 7, 1927. In reduction of Sn compounds, a salt which acts as a catalyst (such as ZnCl_2 , FeCl_3 or NH_4Cl) and a collecting metal such as Ni are added during or after the reduction and the mixt. is heated. The Sn and Ni may be recovered electrolytically.

Annealing metal bands. O. BUSSE and MANSFIELD A.-G. FÜR BERGBAU UND HÜTTENBETRIEB. Brit. 296,146, June 11, 1927. An intermediate layer of heat-resisting material such as asbestos is inserted between the bands and the sole of the annealing oven to take up dirt, splinters, etc., which may be attached to the bands.

Annealing metal sheets. AUSTIN LE BOUTILLIER (to Western Electric Co.). U. S. 1,706,725, March 26. Sheets of metal such as Ni-Fe alloy to be annealed are interleaved with metallic plates having an oxide scale to prevent welding of the sheets together during annealing.

Annealing silicon-steel sheets. WILLIAM E. CAUGHERTY and CARL J. STROBLE (to Allegheny Steel Co.). U. S. 1,706,438, March 26. A stack of sheets is built up upon a flat surface within a furnace heated to annealing temp. while ventilating the furnace so that the gases given off by the sheets during annealing are dissipated and their reabsorption is prevented.

Alumino-thermic welding of rails. F. LANGE. Brit. 295,774, May 28, 1927. Mech. features.

Electric arc welding. MICHAEL ZACK. U. S. 1,707,036, March 26. A system of operation is described in which electrodes are used, one of which is formed of carbon and another of metal.

Arc-welding electrodes. B. TURNER and FERRO-ARC WELDING CO., LTD. Brit. 295,514, Aug. 26, 1927. An insulating material of higher m. p. than the outside coating (which may be of blue asbestos yarn) is inserted between the individual wires of a twin electrode for use with a. c. to avoid unequal melting of the electrode metal. White asbestos may be used and may be treated with fluxes such as lime, china clay, Na silicate or Na_2CO_3 . Cf. C. A. 22, 4456.

Welding rails by the thermo-aluminic process. J. WATTMAN. Brit. 295,459, May 28, 1927. Mech. features.

10—ORGANIC CHEMISTRY

CHAS A. ROUILLER and CLARENCE J. WEST

Structure of aliphatic hydrocarbons. F. M. SHERMYAKIN. *J. Russ. Phys.-Chem. Soc., Chem. Pt.* 60, 871-83(1928).—Baeyer's strain theory remains in force in the case of C rings contg. 5 members or less, as their atoms cannot be so arranged as to avoid strain. In the case of all other rings, the C atoms can be spatially arranged in several different ways which represent a consecutive series of configurations. The sizes and the angles of the centric configurations of C_6H_6 and C_6H_{12} have been calculated by the method of Ingold and Short, and the results, which have been verified experimentally, show that, for C_6H_6 , the configuration assigned by Henri (cf. C. A. 20, 329) is the most stable one, whereas for C_6H_{12} , C_7H_{14} and C_8H_{16} the most stable configuration is octahedric and for C_7H_{12} and C_8H_8 (with sym. disposed double links) the most stable configuration is the hexahedric one.

BERNARD NELSON

The action of sulfuric acid on olefins, etc. W. R. ORMANDY and E. C. CRAVEN. *J. Soc. Chem. Ind.* 47, 317-20T(1928).—It was shown in an earlier paper (C. A. 22, 2919) that paraffins are formed by the interaction of H_2SO_4 and olefins or alic. contg. 3 or more C atoms. This paper is another contribution on the mechanism of these reactions. From open-chain olefins ($\text{MeHC}:\text{CH}_2$, butylenes and amylenes) and an excess of 98% H_2SO_4 at a temp. below 25° were obtained large amts. of open-chain paraffins, which sepd. from the mixt., and "acid wash oils," which remained in the

acid soln., but after diln. could be extd. with pentane. No alcs. were formed from the higher olefins beginning with C_4 . The mean phys. properties of the paraffins, which were colorless, pleasant smelling, mobile oils of a very complex nature, were: $d_{20} 0.76$, $n_D^{20} 1.43$, $r_L 0.34$, b. $100-350^\circ$, mean mol. wt. 200, mean analysis C = 85%, H = 15%. They did not react with Na at 150° and absorbed only traces of Br. The acid wash oils had a high n and absorbed large quantities of Br; they resembled much the wash oils obtained from alcs. In the case of $MeHC:CH_2$, at least 3 mols. were absorbed by 1 mol. H_2SO_4 , before formation of paraffins occurred. Large amts. of open-chain paraffins were obtained by allowing H_2SO_4 to interact with olefins of higher mol. wt. A mixt. of amylene and PhH reacting with H_2SO_4 yielded phenylated paraffins of unknown constitution, while $MeHC:CH_2$ interacting with $PhSO_3H$ and H_2SO_4 gave only a small quantity of satd. hydrocarbons, the main product being an alkylbenzenesulfonic acid. The reaction of cyclic olefins with H_2SO_4 yielded paraffins of probably polycyclic character. Cyclohexane gave 45.6% sepd. oils, $d_{20} 0.8895$, $n_D^{20} 1.4815$, $r_L 0.3200$. From pinene were obtained 7.5% sepd. oils, $d_{20} 0.9238$, $n_D^{20} 1.4969$, $r_L 0.3166$. From open-chain alcs. ($PrOH$, Me_2CHOH , $BuOH$, Me_2CHCH_2OH), large amts. of paraffins were obtained, whose mean properties were: $d_{20} 0.73-6$, $n_D^{20} 1.41-3$, $r_L 0.33-4$, b. $80-350^\circ$, mol. wt. 170-200, C = 84.8%, H = 15.2%. The Br absorption was very low. The constitution of the acid wash oils could not be ascertained as yet. Me_2CHOH yielded wash oils of probably triolefinic character with the following properties: $d_{20} 0.9025$, $n_D^{20} 1.5$, mol. wt. 260, Br absorption 184%, C = 81.4%, H = 12.7%, S = 3.1%, O = 2.8%. Cetyl alc. yielded paraffin wax, m. 50° . The hydrocarbons obtained from cyclohexanol, and *o*-, *m*- and *p*-methylcyclohexanol were colorless, viscous, of high b. p. and of cyclic and dicyclic character. From mixts. of 2 different alcs. or an alc. and PhH, no condensed paraffins were produced. By bringing Me_2CHOH or $AmOH$ in contact with $PhSO_3H$ small amts. of open-chain paraffins were obtained. No other compds. than olefins and alcs. were found to give paraffins with H_2SO_4 . In the reaction with acetic esters, the formation of paraffins had been noted; however, it was discovered that this reaction was a coupled reaction, the formation of paraffins depending on the amt. of alcs. set free by hydrolysis. G. S.

Ozonization of unsaturated gaseous hydrocarbons. I. Ozonization of ethylene. II. Ozonization of propylene and a gas obtained by cracking. E. BRINER AND P. SCHNORF. *Helv. Chim. Acta* 12, 154-81, 181-6(1929).—An app. is described and illustrated for the prepn. and purification of O_3 , and the measurement of the quantities used in the reaction; it permits a mixing of the O_3 with the gas to be oxidized. The stable products of ozonization of C_2H_2 are $HCHO$ and HCO_2H which result from the decompn. of the ozonides formed by the addn. of 1 mol. O_3 to 1 mol. C_2H_2 :

By the action of H_2O the ozonide is converted into formaldehyde peroxide, which is identical with dihydroxymethyl peroxide (cf. C. A. 17, 2558). In the presence of H_2O and under the most favorable conditions 90% of the O_3 and 75% of the C_2H_2 reacted. The decompn. of the reaction products can be so conducted that the formation of aldehyde is increased at the expense of the formation of acid. The ozonization of C_2H_2 is similar to that of C_2H_4 ; the stable products are $HCHO$, AcH , HCO_2H and $AcOH$, which are formed by interaction of H_2O and the ozonide of C_2H_2 . A gas obtained by cracking, contg. about 15% C_2H_2 , 12% C_2H_4 and 8% C_2H_6 was ozonized; when a slight excess of the unsatd. gas was used the yields were 79% on consumption of O_3 and 59% on C_2H_2 ; with excess O_3 the yields were 55 and 68%, resp. N. A. L.

The reaction between β -pentenyl bromide and ethylmagnesium bromide. CHARLES PRÉVOST. *Compt. rend.* 187, 946-8(1928).— $EtMgBr$ and $EtCH:CHCH_2Br$ give $EtCH:CHPr$, b. 94° , $d^{20} 0.701$, $n_D^{20} 1.4017$, whose oxidation with $KMnO_4$ yields exclusively $EtCO_2H$ and $PrCO_2H$, in equimol. proportion, and $Et_2CHCH:CH_2$, b. 85° , $d^{20} 0.6948$, $n_D^{20} 1.3906$, whose oxidation gives Et_2CHCO_2H and whose bromination gives a dibromide b. 93.5° , $d^{20} 1.5251$, $n_D^{20} 1.5006$. These results confirm the existence of a β -pentenyl ion. The dibromide treated with KOH in alc. yields an acetylenic hydrocarbon b. 87° , $d^{20} 0.7272$, $n_D^{20} 1.4023$. It gives a ppt. with aq. or ammoniacal $AgNO_3$, which is sol. in H_2O , $EtOH$ or an excess of the hydrocarbon. A. L. H.

Methylene bromide. W. W. HARTMAN AND E. E. DREGER. *Org. Syntheses* 9,

56-7(1929).—Reduction of 540 g. com. CHBr_3 (88%) by Na_3AsO_3 (prepd. from 230 g. As_2O_3 and 445 g. NaOH) gives 88-90% of CH_3Br . C. J. WEST

Pentamethylene bromide. J. VON BRAUN. *Org. Syntheses* 9, 70-1(1929).—Benzoylpiperidine (80 g.), treated with cooling with 115 g. PBr_3 and then with 65 g. Br , gives a mixt. of $(\text{CH}_2)_5\text{Br}_2$, PhCN and POBr_3 ; the latter is hydrolyzed by H_2O and the PhCN is hydrolyzed by 40% HBr ; the yield of $(\text{CH}_2)_5\text{Br}_2$ is 65-72%. C. J. WEST

Methanol from hydrogen and carbon monoxide. II. Dimethyl ether. RALPH L. BROWN AND A. E. GALLOWAY. Pittsburgh Expt. Sta. *Ind. Eng. Chem.* 21, 310-3 (1929); cf. C. A. 22, 4104.—The production of Me_2O (I) as a side reaction of the synthesis of MeOH (II) over ZnCrO_4 at 300-400° and 180 atm. has been studied. The formation of I is slow and increases with temp. to 5.2% at 397°, while II reaches a max. of about 30% at 375° and then falls off. High space velocity favors the formation of II. A. S. CARTER

Butyl *p*-toluenesulfonate. A. T. ROOS, HENRY GILMAN AND N. J. BEABER. *Org. Syntheses* 9, 28-30(1929).—A mixt. of 148 g. BuOH and 210 g. $p\text{-MeC}_6\text{H}_4\text{SO}_2\text{Cl}$ is treated with 320 cc. 5 *N* NaOH at such a rate that the temp. does not exceed 15° (3-4 hrs.); another portion of 210 g. $p\text{-MeC}_6\text{H}_4\text{SO}_2\text{Cl}$ is added and then 320 cc. 5 *N* NaOH as before; extn. with petr. ether (b. 60-70°) or C_6H_6 gives 50-4% of $p\text{-MeC}_6\text{H}_4\text{SO}_2\text{OBU}$, b_{10} 170-1°. The ester should be distd. in small lots. The Me ester may be prepd. in a somewhat similar manner in 90% yields. C. J. WEST

Chloromethyl ether. C. S. MARVEL AND P. K. PORTER. *Org. Syntheses* 9, 58-9 (1929).—A mixt. of 350 g. MeOH and 900 g. tech. formalin (contg. 252 g. HCHO) is treated with a rapid stream of HCl for 4-5 hrs., giving 86-9% of ClCH_2OMe . C. J. WEST

Remark on the joint communication with Gustav Rutz: Method for the preparation of nitro- and chloronitroolefins. ERICH SCHMIDT. *Ber.* 61B, 2613(1928); cf. C. A. 23, 372.—The observation that substitution of Cl for H in the system $\text{C}:\text{CHNO}_2$ results in a depression of the refractive exaltation of the system is in agreement with similar observations by v. Auwers on conjugated systems derived from a pure C chain or an at. grouping $\text{C}:\text{CHC}:\text{O}$. C. A. R.

Influence of poles and polar linkings on tautomerism in the simple three-carbon system. I. Experiments illustrating prototropy and anionotropy in trialkylpropenylammonium derivatives. CHRISTOPHER K. INGOLD AND EUGENE ROTHSTEIN. Univ. of Leeds. *J. Chem. Soc.* 1929, 8-14.— $\text{ClCH}:\text{CHCH}_2\text{Cl}$ and Et_2NH give 75% of diethyl- γ -chloroallylamine, b_{10} 55°; HCl salt, m. 221°; picrate, m. 78°. EtI gives triethyl- γ -chloroallylammonium iodide (I), m. 210°; chloride (II), hygroscopic; picrate, m. 125°. The same salts were prepd. from $\text{ClCH}:\text{CHCH}_2\text{Cl}$ and Et_3N in EtOH . Trimethyl- γ -chloroallylammonium chloride (III), m. 63°; picrate, m. 141°. Warming I or II with EtONa gives the $\alpha\text{-EtO}$ deriv. (IV), whose picrate, m. 122-3°; the corresponding tri- Me deriv. (V), m. 111-2°. Warming the chloride of IV with concd. HCl gives triethyl- α -hydroxyammonium chloride, viscous liquid; picrate, m. 145°; chloroplatinate, orange. Similarly V gives an $\alpha\text{-HO}$ deriv., whose picrate m. 149°. $\text{Et}_2(\text{ClCH}:\text{CHCH}_2)\text{N}$ and O_3 give HCl , CO and a base, which may be $\text{Et}_2\text{NCH}_2\text{CHO}$. $\text{Me}_3(\text{ClCH}:\text{CHCH}_2)\text{NCl}$ and O_3 give HCl , CO and betaine. $\text{Me}_3(\text{EtOCH}:\text{CHCH}_2)\text{NOAc}$ and O_3 give HCHO and trimethylethoxyaldehydomethylammonium salts; the picrate m. 168°. Warming the latter with concd. HCl gives the corresponding HIO deriv., whose picrate, m. 182-4°. $\text{Me}_3(\text{HOCH}:\text{CHCH}_2)\text{NOAc}$ and O_3 give the same products as the EtO deriv. Triethyl- α -ethoxyallylammonium picrate, m. 110-1°; the corresponding HO deriv., m. 195-6°. These reactions indicate not only prototropic, but also anionotropic mobility in 3-C systems terminated by 1 NH_4 salt group only. C. J. WEST

Tertiary phosphines containing the butyl radical. WALTER C. DAVIES AND WM. JACOB JONES. Univ. College, Cardiff. *J. Chem. Soc.* 1929, 33-5.— BuMgBr (from 42 cc. BuBr) and 9 g. PCl_3 at 0° give 11 g. tributylphosphine, b_{10} 149.5°, d_4^{20} 0.8118; CS_2 addn. product, deep red, completely dissociated in hot Et_2O or EtOH ; HgCl_2 complex, plastic mass. Methyltributylphosphonium iodide, m. 133.5°; Et deriv., m. 153°. Using POCl_3 , there results tributylphosphine oxide, b. 300°, very hygroscopic needles; the oxide also results from the Bu_3P by boiling in a current of air and by oxidizing with warm 40% HNO_3 . Phenyltributylphosphine, in 16 g. yield from 19 cc. PhPCl_2 , b_{10} 184.5-5.5°, d_4^{20} 0.9115; HgCl_2 compd., m. 160.5°; phenylmethyltributylphosphonium iodide, m. 168°; Et deriv., m. 147°. *p*-Tolyltributylphosphine, in 15 g. yield from 20 cc. $p\text{-MeC}_6\text{H}_4\text{PCl}_2$, b_{10} 197°, d_4^{20} 0.9076; HgCl_2 addn. compd., m. 112°; *p*-tolylmethyltributylphosphonium iodide, m. 130.5°. C. J. WEST

Structure and activation of aliphatic aldehyde molecules. I. Analysis of the spectrum of formaldehyde vapor. SVEND AAGE SCHOU. *J. chim. phys.* 25, 665-721 (1928); cf. *C. A.* 22, 1907, 2325.—A review of the theoretical study of absorption spectra is given as a background to the consideration of the mechanics of the polyatomic system of CH_2O . Depolymerization of trioxymethylene furnished pure CH_2O for observation. In a concn. of 60 mg. per l., 35 bands were found between 3700 and 2500 A. U., with a max. at 2935 A. U. (F band). AcH and EtCHO gave max. absorption at 2940 and 2900 A. U., resp. An extensive mathematical analysis of the spectrum has been made. Rotational states of the mol. were evaluated from series of lines resolved from the bands. Rotational consts. were calcd. and comprehensive tables of observations and calcns. show a good agreement between the data and theory for the double rotation of the mol. The moments of inertia for both normal and activated mols. were detd. and thus the distance between H atoms were calcd. from the moments about the sym. axes through the CO linkages.

A. S. CARTER

α -Bromo- and hydroxyaldehydes. II. Bromination of valeraldehyde. RUDOLF DWORZAK AND ANTON ENENKEL. *Univ. Wien. Monatsh.* 50, 449-58 (1928); cf. *C. A.* 21, 3608.—The starting material was a fermentation AmOH from molasses, b. 128-131.3°, with $[\alpha]_D -2.47^\circ$, or contg. about 42% of $\text{EtMeCHCH}_2\text{OH}$; the aldehyde from this mixt. b. 90-2° and had $[\alpha]_D 0.35^\circ$; the paraldehyde obtained by the action of H_2SO_4 b.₁₀ 122-4° and had $[\alpha]_D 0.04^\circ$. Bromination of the paraldehyde with 4 mols. Br at -5° to -10° and treatment with abs. EtOH gives a mixt. of *monobromovaleraldehyde acetal* (I), b.₁₀ 83°, $d_{18}^{18} 1.29$, $[\alpha]_D 0.12^\circ$, and the *di-Br deriv.*, b.₁₀ 121°, $d_{18}^{18} 1.37$. Boiling I with 5 parts H_2O for 1 hr. gives α -hydroxyvaleraldehyde, b. 120°, which reduces Fehling soln. on warming. III. Preparation of crystalline lactaldehyde and its behavior toward dilute aqueous alkalis. R. DWORZAK AND WILHELM PRODINGER. *Ibid* 459-75.—Detailed directions are given for the sapon. of $\text{MeCHBrCH}(\text{OEt})_2$ and the extn. and distn. of the lactaldehyde (I) formed, 35.4% of I being obtained cryst. Mol. wt. detns. in H_2O indicate the presence of the dimol. form at first, but the monomol. form after 24 hrs. One g. CuO corresponds to 0.4882 g. I. Cryst. I gives the same derivs. as the previously studied liquid form. While I is stable toward air, it is easily oxidized in the presence of alkali. I in 1% NaOH, after 8 days' standing, reduced Fehling soln. only slightly, but considerable Cu_2O sepd. on heating. Four % NaOH after 5 days gave a yellowish brown sirup, corresponding to the compd. $3\text{C}_3\text{H}_4\text{O}_2 \cdot 1 \text{H}_2\text{O}$ (mol. wt. and analyses); this reduces Fehling soln., especially on boiling. Oxidation of I with $\text{Cu}(\text{OAc})_2$ gives AcCHO .

C. J. WEST

Atmospheric oxidation of esters of β -eleostearic acid with monohydric alcohols. A. B. MILLER AND K. L. ROHRBACH. *Ind. Eng. Chem.* 21, 338-42 (1929).—The following esters of β -eleostearic acid were prepd. by esterification of β -eleostearic acid (I), m. 45° (prepd. from American tung oil), and the corresponding alc. with dry HCl as condensing agent: *Me*; *Pr*, light yellow oil, $n_D^{25} 1.4982$; *iso-Pr*, dark oil, $n_D^{25} 1.4940$; *Bu*, dark oil, $n_D^{25} 1.4947$; *benzyl*, dark oil, $n_D^{25} 1.5312$. These esters oxidize rapidly (cf. *C. A.* 22, 943) and completely similarly to the esters of polyhydric alcs. but without drying; splitting forms simpler acids having a tendency to add to the ester mol.; hydrolysis with the formation of I occurs to a limited extent. Associates of several mols. of oxidized ester are usually dissolved in a dispersion of simple oxidized mols.; the acid set free from oxidized esters are mostly di- and polybasic. There is little neutral and no acid hydrolysis and since these esters form abundant strong acids on oxidation, hydrolysis is inhibited in an acid medium. The consts. of the end products vary with the no. of C atoms in the straight-chain alc. esters and are regularly higher or lower in the case of isopropyl and benzyl ester; this is attributed to the relative tendency of the esters to hydrolyze on oxidation, producing I. The *Me* ester oxidized in the presence of I gels, the acid forming an addn. product with the ester (stearic acid does not combine under these conditions). These results confirm the hypothesis that an important function of the alc. group in the esters of I is the stability imparted to the ester, thus detg. the tendency to split off I, which, because of addn. and aggregation of the long C chains, actively influences gel formation.

N. A. LANGE

Cyanoacetamide. B. B. CORSON, R. W. SCOTT AND C. E. VOSE. *Org. Syntheses* 9, 36-7 (1929).— $\text{NCCH}_2\text{CO}_2\text{Et}$ (400 g.), poured into 300 cc. concd. NH_4OH and the mixt. allowed to stand 1 hr., gives 86-8% of $\text{NCCH}_2\text{CONH}_2$, m. 119-20°. Gaseous NH_3 was tried with poor success. The following soly. data are given (g. in 100 cc. 95% EtOH): 0°, 1.3; 12°, 1.7; 26°, 3.1; 38°, 5.0; 44°, 7.0; 52°, 9.5; 62°, 14.0; 66°, 16.3; 69°, 18.7; 71°, 21.5.

C. J. WEST

Butyryl chloride. B. HELFERICH AND W. SCHAEFER. *Org. Syntheses* 9, 32-3

(1929).— SOCl_2 (56 g.), warmed on the H_2O bath and treated with 35.2 g. PrCO_2H , gives 85% of PrCOCl , b. $100-1^\circ$. C. J. WEST

A modified Curtius degradation. II. C. NÄGGLI. *Helv. Chim. Acta* 12, 205-7 (1929).—Polemical. Answer to Lindemann's criticism (cf. C. A. 23, 827) of the term "modified Curtius degradation" (cf. C. A. 23, 113). N. A. LANGE

Symmetrical ethers of the alcohols, $\text{XCH}_2\text{CH}(\text{OH})\text{CH}_2\text{X}$ and $\text{XCH}_2\text{CH}(\text{OH})\text{CH}_2\text{OR}$. L. BLANCHARD. Faculty of Sciences of Angers. *Bull. soc. chim.* 45, 1194-1204 (1928).—Treating $\text{ClCH}_2\text{CH}(\text{OH})\text{CH}_2\text{Cl}$ (I) with SO_2Cl_2 gave 65% of the *dichlorohydrin chlorosulfonate*, $b_{11} 113-4^\circ$, $d_{20} 1.592$, $n_D^{20} 1.48325$. Distg. the chlorosulfonate at 160° produced $\text{CH}_2\text{ClCHClCH}_2\text{Cl}$, b. $154-6^\circ$. One mole SO_2Cl_2 to 4 or 5 moles of I gave the *dichlorohydrin ether*, $[(\text{CH}_2\text{Cl})_2\text{CH}]_2\text{O}$, $b_{11} 141-2^\circ$. From the alk. wash water there was obtained $\text{SO}_2(\text{ONa})\text{OCH}(\text{CH}_2\text{Cl})_2$. $\text{SO}_2(\text{OH})\text{Cl}$ and I liberated HCl and gave $\text{SO}_2(\text{OH})\text{OCH}:(\text{CH}_2\text{Cl})_2$. By substituting $\text{ClCH}_2\text{CH}(\text{OH})\text{CH}_2\text{Br}$ for I in the above reaction the chlorobromohydrin chlorosulfonate was not prepd. but dichloro-1,2-bromopropane, $b_{17} 74-5^\circ$. SO_2Cl_2 and $\text{ClCH}_2\text{CH}(\text{OH})\text{CH}_2\text{Br}$ (1:5) gave 85% of the *chlorobromohydrin ether*, $b_{28} 175-7^\circ$, and a residue of $\text{SO}_2(\text{ONa})\text{OCH}(\text{CH}_2)_2\text{BrCl}$. SO_2Cl_2 and dibromohydrin and chloriodohydrin gave no products that could be identified. B. was unsuccessful in obtaining derivs. of chloromethylin, chloroethylin and chloroamylin with SO_2Cl_2 . R. C. ROBERTS

Partial esterification of polyhydric alcohols. VII. The unreliability of proofs of the structure of disubstituted glycerols. ARTHUR FAIRBOURNE AND GEOFFREY WILSON COWDREY. King's College, London. *J. Chem. Soc.* 1929, 129-35; cf. C. A. 21, 1096.—Previous work has shown that the alleged structures of " β "-monoglycerides were untrustworthy; several " α,β "-disubstituted glycerols have now been prepd and found identical with their " α,γ "-isomers. " α,β "-Diphthalimidohydroxypropane, prepd. by the methods of Philippi and Seka (C. A. 18, 72) and of Gabriel (*Ber* 22, 224 (1889)), m. 204° and are identical; their *mono-Ac* derivs. have also been independently prepd. and found identical, as have the *Bz* derivs.; the former m. 194° , the latter, $194-5^\circ$. On the other hand, different dibromohydrin *p*-nitrobenzoates have been obtained (C. A. 21, 1090). *Allyl palmitate* was not obtained pure; the impure product m. $20-5^\circ$. α,β -Dibromohydrin palmitate, m. 34° ; α,γ -dibromohydrin palmitate, m. 35.5° ; neither reacts with K phthalimide. Either isomer, with $p\text{-O}_2\text{NC}_6\text{H}_4\text{CO}_2\text{Ag}$, gives the same *monopalmitin di-p-nitrobenzoate*, m. 102° . α,γ -Dichlorohydrin triphenylmethyl ether, m. $108-9^\circ$. When direct rotatory evidence is not available, and until the matter is better understood, it would seem reasonable, therefore, (a) when a disubstituted glycerol exists as 2 isomers, to assume, in the absence of proof to the contrary, that these have the structures of their respective parent substances or derivs., and (b) in all other cases, to appreciate that conversion may have occurred.

C. J. WEST

Keto-lactol tautomerism. I. Ring-chain tautomerism in α -carboxy- γ -acetyl- β,β -dimethylbutyric acid and a synthesis of γ -acetyl- β,β -dimethylbutyric acid. MUHAMMAD QUDRAT-I-KHUDA. Imp. College Sci. Tech., London. *J. Chem. Soc.* 1929, 201-9.—Evidence of the existence of the keto-lactol type of tautomerism in some δ -ketonic acids is presented; effect of alteration of the C tetrahedral angle, due to the presence of different substituents, on the tautomeric character of the various acids is also examd. Na (2.3 g.), 500 cc. abs. EtOH, 84 g. $\text{NCCH}_2\text{CONH}_2$ and 108 g. $\text{Me}_2\text{C}:\text{CHAc}$ give nearly quant. 6-hydroxy-2-keto-3-cyano-4,4,6-trimethylpiperidin (I), m. 272° (decompn.). I does not lose NH_3 on treatment with dil. NaOH, does not react with NaNO_2 in cold AcOH and on heating with POCl_3 for 2 hrs. gives 2 keto-3-cyano-4,4,6-trimethyl-2,3,4,5-tetrahydropyridine (II), m. 253° . $\text{NCCHNaCO}_2\text{Et}$ and $\text{Me}_2\text{C}:\text{CHAc}$ in EtOH, heated 4 hrs., give 70% of *Et* α -cyano- γ -acetyl- β,β -dimethylbutyrate (III), $b_{11} 160^\circ$, $d_4^{20} 1.03705$, $n_D^{20} 1.44652$, $[R_L]_D 54.39$ (calcd. 54.43), semicarbazone, m. 168.5° . Shaking with NH_4OH (d. 0.880) for 48 hrs. gives 6-amino-6-hydroxy- α -cyano- β,β -dimethylhexoamide, crystg. with 3 mols. H_2O , decomp. in the steam oven and loses NH_3 when heated with H_2O at 100° ; it does not give a semicarbazone. Hydrolysis of I with concd. HCl by heating 4 hrs. on the H_2O bath gives

quant. the dilactone (IV)

m. 137° (cf. Vorländer and Gärtner, *Ann.*

304, 17 (1898)), also obtained by the hydrolysis of II or III by concd. HCl ; IV slowly

decomps. at 200° with the loss of CO₂ and the production of the unsatd. lactone, Me₂CCH:CMc. O. CO. CH₂(V). Hydrolysis of I with concd. KOH (heating about

28 hrs.) gives α -carboxy- γ -acetyl- β , β -dimethylbutyric acid, m. 95°; semicarbazone, m. 177°; Et ester, b₁₅ 153°, d₄^{20.2} 1.03921, n_D^{20.2} 1.4413, [R_L]_D 65.59 (calcd. 65.55) (semicarbazone, m. 76°); oxidation of the acid with NaOBr gives α -carboxy- β , β -dimethylglutaric acid, m. 173°; heating the acid 5 hrs. at 130–40° gives 25% of IV and 72% of HO₂CCH₂CMc₂CH₂Ac (VI), b₁₆ 162°, d₄^{19.5} 1.03646, n_D^{19.5} 1.44652, [R_L]_D 40.6 (calcd. 40.69); Ag salt; semicarbazone, m. 172° (decompn.); Et ester (VII), b₁₇ 112°, d₄^{19.8} 0.96248, n_D^{19.8} 1.43047, [R_L]_D 49.97 (calcd. 50.05) (semicarbazone, m. 114°). This behavior of the acid suggests that the parent acid is a mixt. of the 2 forms AcCH₂CMc₂CH(CO₂H)₂ and Me₂C. CH₂. C(OH)Me. O. CO(CO₂H)CH₂, approx. in the ratio

of 3:1. β , β -Dimethylglutaric anhydride, heated with twice the calcd. quantity of abs. EtOH for 3–4 hrs., gives Et H β , β -dimethylglutarate, b₁₆ 164°, d₄^{18.1} 1.05574, n_D^{18.1} 1.4403, [R_L]_D 46.97 (calcd., 46.95); Ag salt; the chloride, b₁₄ 117°, with ZnMeI gives VII. The action of AcCl on VI gives V, b₁₆ 82°, d₄^{22.2} 0.98658, n_D^{22.2} 1.45573, [R_L]_D 38.55 (calcd. 38.13). VI, reduced with Na and boiling EtOH, gives β , β , δ -trimethylvalerolactone, b₁₈ 120°, d₄¹⁷ 0.98039, n_D¹⁷ 1.44743, [R_L]_D 38.73 (calcd. 38.70).

C. J. WEST

dl-Alanine. E. C. KENDALL AND B. F. MCKENZIE. *Org. Syntheses* 9, 4–7(1929).—Detailed directions are given for the prepn. of MeCH(NH₂)CO₂H, starting with AcH, NH₄Cl and NaCN, the resulting nitrile being hydrolyzed with concd. HCl; the alanine-HCl is extd. with 95% EtOH and the HCl removed by Pb(OH)₂ followed by Ag₂O. Yield, 52–60%.

C. J. WEST

Levulinic acid. B. F. MCKENZIE. *Org. Syntheses* 9, 50–1(1929).—Cane sugar (500 g.), heated with 250 cc. concd. HCl on the H₂O bath for 24 hrs., and the solid product extd. with Et₂O for 6–8 hrs., gives 22–3% of AcCH₂CH₂CO₂H, b₁₈ 137–9°, m. 30°. Starch may also be used.

C. J. WEST

The technical importance of adipic acid and its derivatives. WALTHER SCHRAUTH. *Chem.-Ztg.* 53, 41–3(1929).—Adipic acid has not been able to compete with other dibasic acids heretofore, but with the recent introduction of special methods of prepn. a product is now obtainable that can be used in baking powders, fruit essences, soft drinks, and hygienic and medicinal preparations in competition with tartaric and other acids. This is of importance as Germany now gets its tartaric acid raw materials from foreign countries. Advantages claimed for baking powders made from adipic acid, in comparison with tartaric acid, etc., are greater CO₂ formation per unit wt., stability of the baking powder itself, more gradual evolution of CO₂, better taste, lower cost, etc. Disadvantages include low soly. in H₂O (1.4 parts in 100 of H₂O at 15°); this is in part offset by its great soly. in hot H₂O, e. g., 180 parts of acid per 100 of H₂O at 100°. For this reason β -methyladipic acid is better to use in soft drinks, as its soly. is much greater. As raw material for making adipic acid *p*-methylcyclohexanol is most important, but the hydrogenated products of certain crude cresols can be used also, although mixts. of lower mol. wt. then result; since these can be employed as such in the leather industry, textiles, dyeing, etc., it really makes little difference technically. Derivatives of adipic and methyladipic acid, such as their esters, are also important, as in the celluloid, artificial leather, lacquer and photographic-film industries, synthetic fats and waxes, perfumes and analytical chemistry.

W. C. EBAUGH

Some transformations of propine- α , γ -dicarboxylic acid. FR. MAKULEC, R. MALACHOWSKI AND L. MANITIUS. *Roczniki Chem.* 8, 576–82; French 582(1928).—The propine- α , γ -dicarboxylic acid (glutinic acid) (I) could not be transformed into the cyclic anhydride (II); the dehydration by Ac₂O gave 4-acetyl-4,6-dihydroxy- α -pyrone (III). Di-Me glutinate, obtained by the action of CH₃N₃ on glutinic acid, b₅ 101.0–1.5°, d₄²⁰ 1.1657, n_D²⁰ 1.48779, has a pungent odor, gives a red color with NaOH and KOH. The *cis*- β -bromoglutaconic acid, C₅H₆O₄Br (IV), from I and 65% HBr, m. 143–4°, sol. in H₂O and alc. The β -bromoglutaconic anhydride, C₅H₄O₄Br (V), from IV and Ac₂O, m. 148–9°. The *cis*- β , γ -dibromoglutaconic acid, C₅H₄O₄Br₂ (VII), from I and Br in AcOH crystals from 35% HBr in needles, m. 132°, sol. in H₂O, alc., ether; its Ag salt is insol. in H₂O. The *cis*- α , β , γ -tribromoglutaconic acid, obtained by the further action of Br on VII, m. 151°. The β , γ -dibromoglutaconic acid anhydride, C₅H₂O₄Br₂ (VI), m. 93–96°, sol. in C₆H₆, CHCl₃, slightly sol. in ether.

JAROSLAV KUČERA

Replacement by chlorine of the hydroxyl group in esters of hydroxy acids by

means of phosphorus oxychloride and pyridine (steric course of the substitution). THEODOR WAGNER-JAUREGG. Technische Hochschule, Zurich. *Helv. Chim. Acta* 12, 61-3(1929).— POCl_3 can be used to replace OH by Cl in HO acids, provided pyridine is present. In its absence, dehydration often occurs. The chlorination is often accompanied by a reversal in polarity of the optically active acids. *d*-Chlorosuccinic ester is prepd. by treating 12.2 g. of *l*-malic acid ($\alpha_D^{16.6} -4.62^\circ$) and 11.9 g. pyridine with 11.5 g. of cold POCl_3 , allowing to stand for 1 hr. in a freezing mixt. After 12 hrs. standing at room temp., the mass is decompd. with H_2O and extd. with CHCl_3 . The ext. is washed with H_2O , dried with Na_2SO_4 and distd. It b_{10-1} 110-1° (yield 4.8 g.). After refractionation it b_{10-1} 106-7° (uncor.), $\alpha_D^{20} +36.6^\circ$. *Me phenylchloroacetate*: 7.4 g. of *d*-mandelic acid, α_D^{18} (CS_2) 172 (pure acid: 214°) + 7.1 g. pyridine + 6.8 g. POCl_3 yielded 4.2 g. b_{12-20} 133-40°. After refractionation it b_{12-20} 130-1 (cor.) $\alpha_D^{18} -62.2^\circ$ (calcd. for optically pure product -77.4°). *dl*-Isomer: 12.5 g. *dl*-mandelic acid + 12 g. pyridine + 11.5 g. POCl_3 gave 6.8 g. of *dl*-product; b_{12-18} 129-30° (cor.).

G. CALINGAERT

Modern tartaric acid industry. KARL DOPP. *Deutsche Essigind.* 33, 35 (1929).—A presentation mainly of statistical data covering the production of tartaric acid in European countries.

W. O. F.

Alkyl derivatives of octacyanotungstic acid. FRANZ HÖLZL. *Monatsh.* 51, 1 22 (1929); cf. *C. A.* 22, 3137; 23, 820 —H has prepd. intermediate products of the hydrolysis of isonitriles. Several Ag salts of $\text{H}_4\text{W}(\text{CN})_8$ with MeI yield simple and condensed alkyl derivs. which are shown to contain isonitrile groups. These add water or ale to form half-hydrolysis products of isonitrile, contg. the acid group $\text{HO}-\text{C}-\text{NHMe}$. Further hydrolysis yields acid and amines; NaOH and MeI give carbamines; analyses and structures of about 10 compds. are given. A typical simple formula is $\text{W}(\text{CN})_6(\text{CNMe})_2(\text{HO}-\text{C}-\text{NHMe})_2$.

VALENTINE F. HARRINGTON

Selenocyanopropionic acid. I. ARNE FREDGA. Univ. Upsala. *J. prakt. Chem.* 121, 56-69(1929).— $\text{MeCH}_2\text{BrCO}_2\text{K}$ and KSeCN in a little H_2O give 50-60% of the *K* salt, thin needles, hygroscopic, of $\text{MeCH}_2(\text{SeCN})\text{CO}_2\text{H}$ (I), m. 69-70° (Simon, *Monatsh.* 26, 959(1905), reports the acid as not m. at -15°); I decomp. in the air after several weeks, giving diselenodilactylic acid (II). The elec. cond. of the acid is reported at 25°. The strychnine salt of I yields a free acid with $[\alpha]_D^{19}$ (H_2O 0.1*N* soln.) but on further purification the acid was lost through decompn.; the quinine salt, crystg. with 3 H_2O , yields an inactive free acid. Active I was obtained from the active Br acid and has $[\alpha]_D^{19}$ 54.8° (as *K* salt), increased after 5 crystns. to 65°. β -Selenocyanopropionic acid, m. 58°; *K* salt; cond. values indicate that this acid is about 16 times weaker than I. If in the prepn. of I an equal vol. of concd. HCl is added and the soln. heated at 80-90° (HCN removed by a stream of air), there result, upon neutralization with KOH, 2 *K* salts, both crystg. with 2 H_2O , from which 2 forms of II are obtained, m. 70.5-25 and 107-8°; both have the mol. wt. of 304.4 (calcd. 372); the higher-melting form may be the *dl*-form. I is rather stable in neutral soln; NH_4OH does not attack it at room temp.; concd. alkali decomp. it with sepn. of Se, yet the principal product is II; in acid soln. the formation of I is quant. The reaction is probably monomol.

C. J. WEST

Butyl carbamate. TENNEY L. DAVIS AND STANLEY C. LANE. *Org. Syntheses* 9, 24-6(1929).—A soln. of 180 g. $\text{CO}(\text{NH}_2)_2$ in 1200 cc. BuOH is refluxed 30 hrs.; extn. with ligroin (b. 60-90°) gives 75-6% of $\text{C}_4\text{H}_9\text{CO}_2\text{NH}_2$, b_1 108-9°, m. 53-4°; the residue (9-14%) is practically pure cyanuric acid. The carbamate b. 203-4° with some decompn. into BuOH and cyanuric acid.

C. J. WEST

Derivatives of hydantoin-3-acetic acid. R. LOCQUIN AND V. CERCHEZ. *Compt. rend.* 188, 177-9(1929).—With SOCl_2 hydantoin-3-acetic acid (I) gave its chloride, from which its anilide, m. 215°, *Et* aminomalonate, m. 172-3°, *Et* glycoylate, m. 168°, and methyl-3-isopropyl-5-pyrazoline deriv., m. 185°, were prepd. Aq. NH_3 and I gave hydantoin-3-acetamide, m. 225-6°.

R. C. ROBERTS

Theory of color on the basis of molecular strain. V. Absorption spectra and dissociation constants of organic salts of violuric acid. NARENDRA NATH GHATAK AND SIKHIBHUSHAN DUTT. Allahabad Univ. *J. Indian Chem. Soc.* 5, 665-72(1928), cf. *C. A.* 21, 3194.—In the course of a study of the phenomenon of color in violates and violuric acid (I), G. and D. have studied the absorption spectra and detd. the disocn. consts. of 29 org. salts of I. The color produced by salt formation is in general directly proportional to the basic character of the org. base.

LOUISE KELLEY

Reduction behavior of sugars and their degradation products. F. FISCHLER, K. TAUFEL AND S. W. SOUQI. Univ. München. *Z. angew. Chem.* 41, 950-5(1928) —

Twenty-one sugar reagents are listed and their compns. given. A table shows the behavior of various sugars towards AgNO_3 , KMnO_4 , $\text{K}_2\text{Cr}_2\text{O}_7$, HgCl_2 , Fehling soln. and Ost's soln. under various conditions. The original should be consulted for the details and conclusions.

C. J. WEST

Reaction between sugars and amino acids. HANS V. EULER AND EDVARD BRUNIUS. Univ. Stockholm. *Ann.* **467**, 201-16(1928).—F. p. detns. on mixts. of dextrose and glycylglycine in H_2O at p_{H} 6.0-9.2 show that condensation increases rapidly with increasing p_{H} . This is contrary to the results of Waldschmidt-Leitz and Rauchalles (*C. A.* **22**, 2381), but is similar to the reaction between dextrose and glycine. The decolorization of methylene blue soln. by a mixt. of dextrose and glycylglycine at p_{H} 9.1 is rather slower than with a mixt. of dextrose and glycine. This last mixt. decolorizes methylene blue still more rapidly at p_{H} 10.5. A mixt. of levulose and glycine begins to decolorize methylene blue at p_{H} 9.1; at p_{H} 10.3, reduction is more rapid.

C. J. WEST

Decomposition of sugars and glucosamines in a dilute alkali solution. RYUKI MASUI. Osaka Med. Coll. (*Osaka J. Med.* **27**, 1137-46(1928).—The quantity of methylglyoxal formed on distg. a weakly alk. soln. (0.02 M Na_2CO_3 soln. mixed with Na_2SO_3 to make its amt. 6% of the Na_2CO_3) decreases in the order fructose, glucose and glucosamine, the distn. residue being lactic acid. The decompn. of glucose is retarded by the use of a phosphate buffer. No such reaction could be detected with starch, alanine and cane sugar.

K. SOMEYA

The chemistry of organic compounds with high molecular weight, with respect to the structural theories of Kékulé. XII. H. STAUDINGER. Freiburg-in-Breslau Univ. *Z. anorg. Chem.* **42**, 37-40, 67-73(1929).—A general article, in which S. summarizes the views advocated by himself in his previous publications: highly polymerized substances are formed by smaller units bonded together by ordinary linkages, not residual valences; the length of the C chain det. the characteristics of the compds.; in cryst. compds., the chain arranges in such a way that a lattice may result; x-ray investigations give no clue as to the magnitude of the chain, since one chain may involve several elementary cells.

ALBERT L. HENNE

General structural chemistry of the higher carbohydrates. M. BERGMANN. *Z. physik. Chem.* **130A**, 692-4(1928).—A short theoretical discussion of the structure of carbohydrates, based on the behavior of lactaldehyde and its derivs.

C. J. WEST

Aldehydes from acetylenecarbinols. IV. **1-Methyl-4-isopropylcyclohexylidene-3-acetaldehyde.** H. RUPE AND ALOIS GASSMANN. *Helv. Chim. Acta* **12**, 193-204(1929); cf. *C. A.* **23**, 2928.—*d*-Menthone (I) was prepd. in 90% yield by adding the theoretical quantity of H_2 to 300 g. pulegone and 100 g. Ni catalyst in 1500 cc. 70% EtOH during 3.5-4 hrs., steam distg. to remove EtOH (which was then fractionated to recover I and this was added to the residue from the steam distn.); the crude I was shaken with ice-cold KMnO_4 soln. until the KMnO_4 color was no longer discharged, then shaken with Beckmann's soln. keeping below 45° , warmed to 50° for 5 mins., Na_2CO_3 soln. added and steam distd.; it b_{12} 89° , $[\alpha]_D^{20}$ 25.7° ; semicarbazone, m. 181° ; oxime, purified by distn., b_{12} 132.3° , m. 59° . **1-Methyl-4-isopropyl-3-ethinylcyclohexanol** (II) is obtained when 350 g. I is added slowly (15-20 g. in 5 mins.) to 106 g. powd. NaNH_2 and 400 cc. pure PhH in a 1.5-l. flask with 3 necks and fitted with a dropping funnel, a reflux condenser closed with soda-lime, a stirrer and stuffing box, then warmed 2.5 hrs. longer on a water bath, cooled, filtered through glass wool into a 2.5-l. flask, the filter washed with abs. Et_2O , cooled, evacuated until the Et_2O begins to boil, then adding purified C_2H_2 with shaking and cooling until the pressure is 0.7 atm.; after standing in the ice box overnight, ice and dil. HCl are added, the Et_2O + PhH is layer sepd.; unchanged I is removed by adding 15 g. $\text{N}_2\text{H}_4\text{CONH}_2$, HCl + K_2CO_3 , allowing to stand 24 hrs., adding H_2O and removing II by steam distn.; it is a colorless oil with a slight peppermint odor, which was purified by forming the Ag salt (20 g. AgNO_3 in 60 cc. H_2O + the calcd. amount NH_4OH) and then decomp. with NH_4CNS and steam distg.; it b_{12} $101.5-2.5^\circ$; crude II can also be purified by prepn. of the Bz ester in $\text{C}_6\text{H}_5\text{N}$, steam distg. to remove I and then hydrolyzing the residue of pure Bz ester with alc. KOH. When 120 g. II in 600 g. 70% HCO_2H (5 parts techn. 86% HCO_2H and 1 part H_2O) was warmed under reflux with stirring for 0.75 hr., cooled with ice, neutralized with Na_2CO_3 , extd. with Et_2O , the ext. dried over MgSO_4 and distd., it gave 85 g. of crude **1-methyl-4-isopropylcyclohexylidene-3-acetaldehyde** (III), $\text{MeCH}_2\text{CH}_2\text{CH}_2\text{CH}(\text{C}_6\text{H}_7)\text{C}(\text{CHCHO})\text{CH}_3$, in the fraction b_{12} $107-13^\circ$; the

semicarbazone, m. $146-7^\circ$, was prepd. and on hydrolysis gave pure III, b_{12} 111° , $[\alpha]_D^{20}$

82.9°, d_4^{20} 0.9115; *oxime*, colorless crystals from EtOH, m. 93°, $[\alpha]_D^{20}$ 103.09° (PhH), d_4^{20} 0.8846; this *oxime* (15 g.) when hydrolyzed by boiling 0.75 hr. with 24 g. $H_2C_2O_4$ and 100 cc. H_2O gave I. Treatment of III in Et_2O with $EtMgBr$ gave [4-methyl-2-isopropylcyclohexylidene]methylethylcarbinol (IV), $CH_3.CHMe.CH_2.CH_2.CH(C_2H_5).C$.

H:CH.CH(OH)Et, which is partly dehydrated to [4-methyl-2-isopropylcyclohexylidene]-2-butene (V), $C_{10}H_{18}:CH.CH:CHMe$, which was sepd. by heating with sufficient Na to react with IV, then removing V by distn. *in vacuo*; V is an oil, b_{12} 99°; IV was obtained by adding dil. HCl to the Na alcoholate, extg. with Et_2O , washing with Na_2CO_3 and distg. *in vacuo*; it is a yellow, viscous oil, b_{12} 125°. Oxidation of 20 g. III in Na_2CO_3 with 5.2 l. 4% $KMnO_4$ added with stirring and cooling during 6 hrs., filtering, evapg. the filtrate to 1 l. acidifying with HCl, extg. with Et_2O and distg. *in vacuo* into 2 fractions gave 4-5 g. b_{12} 167°, which is a ketonic acid deriv. of β -methyl- δ -isobutyrylvaleric acid and forms a semicarbazone, m. 152° (cf. Baeyer and Oehler, *Ber.* 27, 1914(1894), 29, 27(1896)); the fraction b_{12} 206-12° (10 g.) is β -methyladipic acid. Reduction of 50 g. III in 350 cc. EtOH, 150 cc. H_2O and 100 g. Ni consumed 6.7 l. H_2 during 3 25 hrs.; after removing the EtOH with steam, extg. with Et_2O , drying with $MgSO_4$, evapg. the Et_2O , fractionally distg. at 12 mm. 25 g. of 1-methyl-4-isopropylcyclohexane-3-acetaldehyde, $C_{10}H_{18}CH_2CHO$, was obtained, b_{12} 106-7°, d_4^{20} 0.9032, $[\alpha]_D^{20}$ -51.28, n_D^{20} 1.46111; the semicarbazone, m. 222°; *oxime*, m. 102°, d_4^{20} 0.8855, $[\alpha]_D^{20}$ 34.11.

N. A. LANGE

Properties of conjugated compounds. VI. Dibromination products of cyclic butadienes. ERNEST H. FARMER AND WM. D. SCOTT. *Imp. College Sci. Tech., London. J. Chem. Soc.* 1929, 172-80; cf. *C. A.* 22, 3391.—When $\Delta^{1,4}$ -cyclohexadiene is dibrominated in C_6H_{14} or $CHCl_3$ below -15° and the solvent removed immediately, without application of heat, a mixt. of 2 isomeric di-Br derivs., a liquid and a solid, m. 68°, is obtained; from their behavior, they are probably isomeric 1,2-dibromo- Δ^2 -cyclohexenes. Each of these substances passes readily into a 3rd solid isomer at room temp. or, more rapidly, on heating; this is the 1,4-di-Br deriv., m. 108°. The isomerization of the original solid form is slow in the dry state, requiring several weeks, that of the liquid is more rapid (8% at 15° in 25 hrs., 40% at 100° in 15 mins.); both forms change readily in a solvent. The 1,4-di-Br isomer was the only product isolated when there was a delay of 3 days in working up the mixt. or when heat was used in removing the solvent. The 1,4-isomer is very slowly oxidized; the solid 1,2-isomer with $KMnO_4$ in Me_2CO at 0° gives 25% of 1,2-dibromo-3,4-dihydroxycyclohexane, m. 96-8°; the liquid 1,2-isomer gave only a trace of this compd. Further oxidation gave only $(CH_3CO_2H)_2$. Bromination of cyclopentadiene in C_6H_{14} at -15° gives a mixt. of *trans*-1,4-dibromo- Δ^2 -cyclopentene (I), m. 45-6°, and 1,2-dibromo- Δ^3 -cyclopentene (II), d_{20} 1.8867. The amt. of I that could be frozen out varied considerably with the proportion of diluent used. With $CHCl_3$, less than 2% of I was obtained, the product consisted of a mixt. of II and the *cis*-I. On distn. II is converted into *cis*-I. On oxidation these derivs. behave as reported by Thiele (*Ann.* 314, 296(1900)).

C. J. WEST

1,3,5-Diphenylcyclohexenone and its reactions. A. D. PETROV. *Leningrad Inst. Agron. J. Russ. Phys.-Chem. Soc., Chem. Pt.* 60, No. 9, 1441-5(1928).—1,3-Diphenyl-5-cyclohexenone was prepd. by the method of Knövenagel and Schmidt (*Ann.* 281, 59) and, after a series of recrystns., it m. 82-3°, and not 70-2° as found by K. For the identification of the ketone, the latter was hydrogenated under pressure with Ni_2O_3 and hexahydrotoluene, whereupon the 2 isomers of 1,3-dicyclohexylcyclohexene which have recently been studied by Schrauth (*C. A.* 17, 1221) were obtained. For the purpose of dehydrogenating the ketone, unsuccessful attempts were first made to obtain Br addn. products. The dehydrogenation had to be effected thus: 10 g. diphenylcyclohexenone was heated at 300° for 1.5 hrs. in a long-necked flask with 5 g. activated C with Pt deposited on its surface. Evolution of H was observed. On cooling, the dehydrogenation product was extd. with C_6H_6 and, after repeatedly being boiled with petroleum ether to sep. the small quantity of tar formed, m. 88-92°. $CH:CPh.CH_2.CPh.CH_2.CO \rightarrow H_2 + CH:CPh.CH:CPh.CH:C(OH)$. Thus

the action of a high temp. in presence of a dehydrogenating catalyzer is a more universal and powerful means of transforming unsatd. cyclic ketones into phenols than through the intermediate production of a bromide. The $Ph_2C_6H_3OH$, on being heated for 1.25 hrs. with $PhNCO$ in presence of C_6H_6 , gives, with an excellent yield, the phenylmethan, m. 180°. To obtain a hydrogenated product, 30 g. of the ketone was dissolved in 200

cc. abs. EtOH, 20 g. metallic Na was gradually introduced through the reflux condenser, then H_2O and dil. H_2SO_4 were added to weak acid reaction, after which the alc. was evapd. and the hydrogenation product was extd. with ether. 1,3-Diphenyl-5-cyclohexanol, $C_{18}H_{20}O$, which is thus obtained in 50% yield, formed after 3 crystns. snow-white needles, m. 127° . Its phenylurethan, m. 152° . By oxidation of 1,3-diphenyl-5-cyclohexanol either by boiling 6–8 hrs. with a chromic mixt. with frequent agitation, or by CrO_3 in AcOH, the corresponding ketone 1,3-diphenyl-5-cyclohexanone, $C_{18}H_{18}O$, is obtained in 70% yield in needles, m. $139-40^\circ$. The oxime, obtained by heating for 2 hrs. on a water bath 1 g. of the ketone with 1 g. $NH_2OH \cdot HCl$, 50 cc. H_2O and 5 cc. EtOH, m. 201° .

BERNARD NELSON

Nitrostyrene. DAVID E. WORRALL. *Org. Syntheses* 9, 66–8(1929).—Details are given of the condensation of BzH and $MeNO_2$ by NaOH, which gives 80–3% of PhCH:CHNO₂.

C. J. WEST

Iodobenzene. F. B. DAINS AND R. Q. BREWSTER. *Org. Syntheses* 9, 46–8(1929).—A mixt. of 381 g. I and 400 g. C_6H_6 at 50° , slowly treated with 275 cc. HNO_3 (d. 1.50), gives 86–7% of PhI. Stirring decreases somewhat the time of reaction. A test for the presence of NO_2 compds. is given.

Some derivatives of *p*-bromoethylbenzene and their organo-magnesium compounds. RAYMOND QUELET. *Bull. soc. chim.* 45, 75–97(1929); cf. *C. A.* 22, 231.—Addn. of 30 cc. of Br_2 to 110 g. of cold *p*-bromoallylbenzene (I) gave upon distn. 60% of 1-*p*-bromophenyl-2,3-dibromopropane (II), b_{11} $178-80^\circ$, d_4^{17} 1.950, n_D^{17} 1.622. Slow addn. of 120 g. of II to 200 cc. of AcOH contg. 25 g. of Zn, followed by boiling for 8 hrs., gave 60% of I, b_{11} 96° , b_{710} $222-3^\circ$. Heating I with K_2CO_3 in EtOH for 24 hrs. gave 40% of *p*-bromopropenylbenzene (III), b_{11} 110° , m. 35° , d_4^{16} 1.332, n_D^{16} 1.590; at higher temp. in AmOH, 75% was obtained in 6 hrs. With BzO_2H in $CHCl_3$, I gave *p*-bromobenzylethylene oxide, b_{10} 132° , d_4^{10} 1.430, n_D^{10} 1.570. 1-*p*-Bromophenyl-3-butene (IV) was prepd. (*C. A.* 21, 2466) and brominated to the 3,4-dibromobutane and again dehalogenated with Zn to give IV. One mol. of $p-BrC_6H_4MgBr$ with 45 g. of AcH gave 45% of 1-*p*-bromophenyl-1-ethanol (V), b_{11} 130° , d_4^{18} 1.464, n_D^{18} 1.574. Ninety-five percent of V was also prepd. by adding 80 g. of $p-BrC_6H_4CHO$ in ether to 0.5 mol. of $MeMgI$. Heating 5 g. of V with 3 g. of $PhNCO$ and crystg. from EtOH gave the phenylurethan deriv., m. $103-4^\circ$. V (30 g.) in 100 cc. of PhH was heated with 10 g. of P_2O_5 for 1 hr., washed with H_2O and distd., giving 10 g. of *p*-bromostyrene, b_{11} $87-8^\circ$, d_4^{18} 1.401, n_D^{18} 1.599, which gave *p*-bromophenyl-1,2-dibromoethane, m. 61° , with Br_2 . 1-*p*-Bromophenyl-1-propanol, b_{11} $140-1^\circ$, d_4^{18} 1.405, n_D^{18} 1.561 (phenylurethan, m. 102°) was prepd. from $p-BrC_6H_4MgBr$ and EtCHO and converted to 60% of III by heating with $KHSO_4$, or 80% by the use of P_2O_5 . With Br_2 , III gave 1-*p*-bromophenyl-1,2-dibromobutane, m. 62° ; with BzO_2H in $CHCl_3$, 80% of 1-*p*-bromophenyl-2-methylethylene oxide, b_{11} $123-4^\circ$, d_4^{11} 1.426, n_D^{11} 1.570. In a similar manner 1-*p*-bromophenyl-1-butene was prepd. (*C. A.* 22, 1341), but in this case, the use of P_2O_5 was not successful. A. S. C.

***o*-Nitroaniline.** LOUIS EHRENFELD AND MILTON PUTERBAUGH. *Org. Syntheses* 9, 64–5(1929).—2,4- $O_2N(HO_2S)C_6H_4NH_2$ (218 g.), refluxed with 775 cc. concd. H_2SO_4 and 950 cc. H_2O for 1 hr., gives 56% of $o-O_2NC_6H_4NH_2$.

C. J. WEST

Bis-semidine inversion in aromatic dihydrazo compounds. PRAPHULLA C. GUHA AND HIRENDRA K. BANERJEE. Univ. of Dacca and Indian Inst. Sci., Bangalore. *J. Indian Inst. Sci.* 11A, 231–9(1928).— $PhNHNHCS_2NH_2NPh$ (50 g.), heated at 80° for 3–4 hrs. and then at 90° , gives 30–40 g. $CS(PhNHNH)_2$; heating with 3% HCl for 30 mins. at 30° and then 1 hr. at $60-5^\circ$ out of contact with air, gives diaminodiphenylthiourea (I); attempts to isolate the free base, the HCl salt, the disulfide or metallic derivs. proved futile, black, tarry substances being obtained. The acid soln. of I, diazotized and treated with $\beta-C_6H_4OH$, gives thiocarbamidobisbenzenesazo- β -naphthol, deep orange, m. $131-2^\circ$; the dimethylaniline deriv., deep yellow, m. $164-6^\circ$; the resorcinol deriv., brick-red, m. 158° (explosively). The neutral soln. of I, heated with $PhNCS$ for 3–4 hrs., gives diphenylthiocarbamidodiphenylthiocarbamide, brown, m. $182-3^\circ$; $PhNCO$ gives diphenylcarbamidodiphenylthiocarbamide, m. $238-40^\circ$; $HCHO$ gives dimethyleneaminodiphenylthiocarbamide, does not m. 300° . Diaminodiphenylcarbamide, obtained by the inversion of $(PhNHNH)_2CO$, could not be isolated; the diazo soln. and $\beta-C_6H_4OH$ give carbamidobisbenzenesazo- β -naphthol, deep red, m. $131-2^\circ$; the dimethylaniline deriv., yellow, m. $160-1^\circ$; the resorcinol deriv., brick-red, m. 157° .

(decompn.). *Diphenylcarbamidodiphenylcarbamide*, m. 236-8°; *dimethyleneamino-diphenylcarbamide*, does not m. 300°. Reduction of $\text{CS}(\text{NHC}_6\text{H}_4\text{NO}_2\text{-}p)_2$ gives *p-aminophenyl-p-phenyleneguanidine* (II), m. 295° (decompn.); HCl salt, crystals with $2\text{H}_2\text{O}$, does not m. 300°; the diazo soln. gives a deep red azo dye with $\beta\text{-C}_{10}\text{H}_7\text{OH}$; PhNCS gives *phenylthiocarbamidophenyl-p-phenyleneguanidine*, does not m. 300°. $p\text{-C}_6\text{H}_4(\text{NHAc})_2$, CS_2 and EtOH , heated 3 hrs., give *p,p'-diacetylaminodiphenylthiocarbamide*, m. 239-40°, which on hydrolysis with HCl gives II. $\text{CO}(\text{NHC}_6\text{H}_4\text{NH}_2)_2$, diazotized and treated with $\beta\text{-C}_{10}\text{H}_7\text{OH}$, gives *Na carbamidobishenzeneazo- β -naphtholate*, red, m. 263°; with PhNCS there results *diphenylthiocarbamidodiphenylcarbamide*.

C. J. WEST

Action of phenylmagnesium bromide on phosphorus pentachloride. J. H. KOLI TOWSKA. *Roczniki Chem.* 8, 568-75 (575 French) (1928).—By the action of PhMgBr on PCl_5 the following compds. are obtained: Ph_2PPh , m. 79-80°; Ph_2PCl_2 ; *tetra-phenylphosphonium bromide*, $(\text{C}_6\text{H}_5)_4\text{PBr} \cdot 2\text{H}_2\text{O}$, m. 286-8°, sol. in H_2O , alc. insol. in ether, and crystals of the etherate $\text{PhMgBr} \cdot \text{MgBr}_2 \cdot \text{MgCl}_2 \cdot 4\text{Et}_2\text{O}$. PPh_3 forms with HgCl_2 a compd. $(\text{Ph}_2\text{P})_2\text{HgCl}_2$, white crystals, insol. in water and ether; the formation of this compd. can be used for titration of PPh_3 .

JAROSLAV KUČERA

β -Substituted alkylarsonic acids and derivatives. I. S. M. SHERLIN AND G. I. EPSTEIN. Moscow High Tech. *J. Russ. Phys.-Chem. Soc., Chem. Part* 60, No. 9, 1487-92 (1928).—By interaction of $\text{ClCH}_2\text{CH}_2\text{OH}$ with Na_2AsO_3 a thick non-crystg. sirup is obtained from which *di-Na β -hydroxyethylarsonate*, $\text{HOCH}_2\text{CH}_2\text{AsO}_3\text{Na}_2$, cannot be isolated, as has already been pointed out by Quick and Adams (C. A. 16, 1560-1). There are also very great difficulties in the way of sepg. the free acid, the latter being extremely hygroscopic. The reduction product obtained in the reaction $\text{HOCH}_2\text{CH}_2\text{AsO}(\text{OH})_2 + \text{SO}_2 = \text{H}_2\text{SO}_4 + \text{HOCH}_2\text{CH}_2\text{AsO}$ could not be sepd. either. *β -Hydroxyethylenearsonic dichloride* obtained by the reaction $\text{HOCH}_2\text{CH}_2\text{AsO} + 2\text{HCl} = \text{HOCH}_2\text{CH}_2\text{AsCl}_2 + \text{H}_2\text{O}$ was sufficiently little sol. to ppt. as a colorless and odorless transparent oil, but the attempt to purify it by a vacuum distn. failed on account of its decompn. accompanied by an abundant emission of gases. The oil is sol. in water, very easily in CHCl_3 , not so easily in Et_2O . Boiling water or alkalis decomp. it sepg. C_2H_4 . The dichloride was acetylated by mixing with a 20% excess of 95-6% AcOH and passing an energetic current of HCl gas: $\text{AcOH} + \text{HOCH}_2\text{CH}_2\text{AsCl}_2 = \text{AcOCH}_2\text{CH}_2\text{AsCl}_2 + \text{H}_2\text{O}$. The action of Ac_2O on the dichloride yields the same product. The *β -hydroxyethylidichloroarsine acetate* thus obtained was fairly stable and could be refractionated several times *in vacuo*; it b₁₀ 120-1° (yield 80-5%), is a colorless and almost odorless viscous oil, strongly refractive, hardly sol. in H_2O , easily in Et_2O and in CHCl_3 . On being boiled with alkalis, or with water, it quant. splits off C_2H_4 , this reaction apparently being due to a migration of the hydroxyl: $\text{HOCH}_2\text{CH}_2\text{As}(\text{ONa})_2 \rightarrow \text{CH}_2=\text{CH}_2 + \text{HOAs}(\text{ONa})_2$. This migration of the hydroxyl seems to be a property common to all β -hydroxy-fatty derivs. of trivalent As, and it explains the decompn. by heat of $\text{HOCH}_2\text{CH}_2\text{AsCl}_2$ and $\text{HOCH}_2\text{CH}_2\text{AsO}$. *Chloroethylidichloroarsine*, $\text{ClCH}_2\text{CH}_2\text{AsCl}_2$, was obtained in 70% yield by treatment of $\text{HOCH}_2\text{CH}_2\text{AsCl}_2$ with POCl_3 or PCl_5 followed by heating and vacuum fractionation, taking the fraction b₁₀ 88-92°; it is a colorless oil b₁₀ 90.8°, b₀ 87°, b₀ 80.6°, d_{20}^{20} 1.8401, hardly sol. in H_2O , easily in C_6H_6 or in CHCl_3 . Like the acetate, it is saponified by water or by alkalis, giving C_2H_4 quant. By its cautious oxidation with H_2O_2 , *chloroethylarsonic acid*, $\text{ClCH}_2\text{CH}_2\text{AsO}_3\text{H}_2$, was obtained in soln. After evapg. this soln. to a sirupy consistency *in vacuo* at 35-45°, the acid crystd. on cooling and could be purified either by a recrystn. from acetone or by pptn. from acetone with CCl_4 ; it forms brilliant small scales, m. 134°, easily sol. in water, MeOH and EtOH , less in acetone, totally insol. in CCl_4 . By the action of phosgene on *β -hydroxyethylidichloroarsine* an oil was obtained which possessed the characteristic odor of chlorocarbonic esters. The product is easily saponified with warm water with emission of CO_2 . In the course of a vacuum distn. it decompd. and gave a fraction b. 78-80° consisting of $\text{ClCH}_2\text{CH}_2\text{AsCl}_2$: $\text{ClCH}_2\text{CH}_2\text{AsCl}_2 \rightarrow \text{CO}_2 + \text{ClCH}_2\text{CH}_2\text{AsCl}_2$. The powerful influence of all enumerated substituents in β -position on the odor of EtAsCl_2 has been noted: under their influence the odor all but disappears.

BERNARD NELSON

Mercury diphenyl. H. O. CALVERY. *Org. Syntheses* 9, 54-5 (1929). Refluxing a mixt. of 900 g. 3% Na-Hg, 180 g. PhBr , 200 cc. dry PhMe or $\text{C}_6\text{H}_5\text{Me}$, and 10 cc. AcOEt for 12 hrs. and extg. with 600 cc. boiling C_6H_6 gives 32-7% of HgPh_2 , m. 121-3°.

C. J. WEST

Interactions of selenium oxychloride and phenols. GILBERT T. MORGAN AND FRANCIS H. BURSTALL. Chem. Research Lab., Teddington, Middlesex, Eng. *J. Chem. Soc.* 1928, 3260-70; cf. Michaelis and Kunckell, *Ber.* 28, 609 (1895); 30, 2833

(1897).—Phenols react with SeOCl_2 in the following two ways: (1) $3\text{HROH} + \text{SeOCl}_2 = (\text{HOR})_2\text{SeCl} + \text{HCl} + \text{H}_2\text{O}$; (2) $3\text{HROH} + \text{SeOCl}_2 = \text{Se}(\text{ROH})_2 + \text{ClROH} + \text{HCl} + \text{H}_2\text{O}$. 33.2 g. SeOCl_2 + 50 cc. CHCl_3 was added to a stirred soln. of 56.4 g. of phenol in 500 cc. of CHCl_3 . After an hr. the mixt. was refluxed until the insol. product had adhered to the containing vessel as a gum. Decantation of the CHCl_3 and trituration of the residue with MeAc gave *tri-4-hydroxytriphenylselenonium chloride* (I) as a white powder, prisms from $\text{EtOH-Et}_2\text{O}$, m. 232° (decompn.). I is a stable salt, dissolving readily in hot H_2O to an almost neutral soln. (p_H 5.7) from which it sepd. in anhyd. condition, insol. in other org. media. Concd. H_2SO_4 dissolved it with evolution of HCl ; the soln. became yellow to green on warming. FeCl_3 gave a reddish purple color. NaOH gave a pale yellow soln. from which CO_2 pptd. the amorphous *tri-4-hydroxytriphenylselenonium oxide* (II), decomp. 240° , insol. in neutral org. media, forms salts with mineral acids. Sulfate, decomp. $269-70^\circ$; bromide, decomp. 237° . AgNO_3 quant. pptd. the Cl in I. I_2 , PtCl_4 , decomp. 244° . I on methylation gave a gum which with HgCl_2 yielded *tri-4-methoxytriphenylselenonium mercurichloride*, identical with that by the method of Hilditch and Smiles (C. A. 3, 425). II stirred gradually into an excess of Br_2 , evapd. to dryness, triturated with Et_2O , and crystd. from EtOH yielded *tri-3,5-dibromotri-4-hydroxytriphenylselenonium bromide* (III), which after repeated evapn. with Br_2 gave prisms (from EtOH) decomp. 261° . $\text{Cl}_2\text{-H}_2\text{O}$ converted III into 4,2,6- $\text{ClBrC}_6\text{H}_2\text{OH}$. From the mother liquors of III, on evapn. and addn. of Et_2O was obtained *tri-3-bromotri-4-hydroxytriphenylselenonium bromide*, m. 251° , insol. in H_2O and org. media (except EtOH), sol. in NaOH (from which soln. CO_2 pptd. an oxide, m. 198°), which was converted by $\text{Cl}_2\text{-H}_2\text{O}$ into 2,4,6- $\text{Cl}_2\text{BrC}_6\text{H}_2\text{OH}$, m. $67-8^\circ$. The MeAc filtrate from I yielded on evapn. a sol. isomer of I which crystd. with $2\text{H}_2\text{O}$, decompd. 125° , sol. in hot H_2O but sepd. on evapn. as a gum. CO_2 pptd. an amorphous oxide from its soln. in NaOH ; methylation yielded a viscid tri-MeO deriv. whose mercurichloride, m. $54-5^\circ$. *o*-Cresol yielded *tri-4-hydroxytri-3-methyltriphenylselenonium chloride* (IV), insol. in H_2O and most org. solvents (except EtOH). Alc. FeCl_3 produced no color, while warm concd. H_2SO_4 gave a green tint. Oxide, decomp. 236° . Nitrate, decomp. 224° . *Tri-5-bromotri-4-hydroxytri-3-methyltriphenylselenonium bromide*, decomp. 253° . The corresponding oxide was decompd. by $\text{Cl}_2\text{-H}_2\text{O}$ into 5-chloro-3-bromo-*o*-cresol, m. 48° . *Di-4-hydroxydi-3-methyldiphenyl selenide* was sepd. from the CHCl_3 washings of IV by steam distn. of volatile substances and petroleum ether extn. of the residue. It was insol. in H_2O , sol. in NaOH and org. media; concd. H_2SO_4 gave a deep green tint. HI decompd. it into 5-iodo-*o*-cresol, m. 72° . *p*-Cresol gave *tri-2-hydroxytri-5-methyltriphenylselenonium chloride*, freed from alc. of crystn. at 110° , decomp. $260-5^\circ$, insol. in H_2O , sol. in NaOH or hot EtOH . Concd. H_2SO_4 gave an olive-green tint on warming; alc. FeCl_3 also gave an olive-green color. Oxide, decomp. 160° , gave with $\text{Cl}_2\text{-H}_2\text{O}$ 3,5-dibromo-*p*-cresol, m. 48° ; with Br_2 *tri-2-bromotri-2-hydroxy-5-methyltriphenylselenonium bromide*, pinkish prisms, decomp. 195° . *Di-2-hydroxydi-5-methylphenyl selenide*, m. 111° , and 5-chloro-4,4'-dihydroxy-3,3'-ditolyl, m. $129-30^\circ$ were obtained as by-products. The selenide yielded 3-iodo-*p*-cresol, m. 38° , on treatment with HI. From resorcinol was obtained *tri-2,4-dihydroxytriphenylselenonium chloride*, pptd. from EtOH by MeAc, m. 206° . FeCl_3 gave a reddish purple color, warm concd. H_2SO_4 a green tint. $\text{Br}_2\text{-H}_2\text{O}$ decompd. it completely. β -Naphthol gave *di-2-hydroxydi-1-naphthyl selenide*, prisms, m. 186° to a red liquid, sol. in alkali; FeCl_3 gave no color, cold concd. H_2SO_4 a green tint. 2-Chloro β -naphthol, m. 70° , was obtained as a by-product. Salicylic acid was condensed without a solvent. Extn. of the reaction mixt. with hot C_6H_6 followed by EtOH gave *disalicyl selenide*, yellowish plates, decomp. 272° , insol. in H_2O , CHCl_3 , C_6H_6 , sol. in Et_2O , MeAc, AcOH. Concd. H_2SO_4 gave a green color, FeCl_3 a bluish violet. *m*-Cresol, α -naphthol, and 2,3- $\text{C}_6\text{H}_3(\text{OH})\text{CO}_2\text{H}$ did not give well-defined products.

DAVID DAVIDSON

The alkyl esters of aromatic sulfonic acids as alkylating agents. V. M. RODIONOV. *Bull. soc. chim.* 45, 109-21(1929); cf. C. A. 20, 1795.—R. and co-workers have found that $\text{PhSO}_2\text{Me(I)}$ can successfully replace $p\text{-MeC}_6\text{H}_4\text{SO}_2\text{Me(II)}$ as an alkylating agent under practically the same conditions. Esters of naphthalenesulfonic acids are also good alkylating agents. The methylation of phenolic aldehydes is best accomplished with the addn. compd. of a Me aromatic sulfonate and PhNMe_2 , since Me halides and Me_2SO_4 , reacting only in alk. soln., give secondary products, perhaps through Cannizzaro reaction. Preliminary expts. indicate that the esters of $p\text{-MeC}_6\text{H}_4\text{SO}_2\text{H}$ cannot be used for alkylation and do not give addn. compds. with tertiary bases. I and hydrazine heated in H_2O give quant. the addn. compd. (III), m. 218° . III with dil. NaOH forms quant. methylhydrazine. Narcosine boiled in H_2O with II and KI gives narceonic

acid, m. 207–8°. p -MeC₆H₄SO₃CH₂CH:CH₂ and KCNS heated in H₂O give only CH₂:CHCH₂NCS (40–3%), b. 148°, which heated with NH₃ and alc. and evapd. forms thiosinamine (allylthiourea), m. 74–5°, in good yield. II warmed with 5% NH₃ in abs. alc. gives MeNH₂, isolated as the HCl salt (30%). EtNH₂ is formed in the same way in only minute amt., confirming R.'s earlier observation that Et esters are in general more inert than Me. Replacing NH₃ by MeNH₂ in the same reaction does not yield the expected secondary amine. Alkylated hydrazines could not be prepd. from N₂H₄ and II because of the violence of the reaction. The Me aromatic sulfonates of PhNMe₂ do not react at all with aliphatic alcs, (Schöpf, *Ann.* 452, 211–67). The Me p -toluenesulfonate of PhNMe₂ and dil. MeONa form PhNMe₂OH, which heated 1–1.5 hrs. with vanillin or protocatechualdehyde gives almost 86% and 58.3%, resp., of veratraldehyde, m. 41–2°. Salicylaldehyde is 72% methylated by II, and the m - and p -aldehydes, 88 and 70%, resp. Me and Et naphthalenesulfonates are prepd. from the sulfonyl chlorides (made from the Na salts of the SO₃H acids and PCl₅) with MeOH or EtOH and 35% NaOH below 20° with these yields: 82% of Me β -naphthalenesulfonate (IV), m. 56°; 68–70% of the Me α -ester (V), m. 72–3°; 65–6% of the Et α -(VI) and Et β -(VII) esters. IV and PhNMe₂ yield 87% of the addn. compd. (VIII), m. 206–8°. V, VI and VII also give addn. compds. with PhNMe₂; that with V, m. 161° and is formed almost quant. Phenol heated with IV gives 80% anisole (IX), b. 153–5°. V gives 70% IX. The Et α -naphthalenesulfonate of PhNMe₂ gives with phenol only phenetole (88%). VIII and morphine give 75% codeine. ClSO₃H and C₁₀H₈ at 85° form 88% 1,5-naphthalenedisulfonyl chloride (X), m. 183°. X is prepd. also from C₁₀H₈(SO₃Na)₂ and PCl₅ or ClSO₃H. X in NaOH and MeOH below 20° yields the di-Me ester (XI), m. 205°. The addn. compd. from XI and PhNMe₂ (in 70% yield), m. 260°, and with morphine gives 73–4% codeine. The quaternary bases of esters of aromatic SO₃H acids are constituted like leucotropes and can also be used to some extent in cotton printing. Leucotrope, PhNMe₂(CH₂Ph)Cl, and EtONa give PhNMe₂(CH₂Ph)OH, which with morphine at 115° forms only peronine (benzyl-morphine) (50%), m. 125–6°.

JANET D. SCOTT

Preparation of xylenols from technical xylydines and ethylphenols from benzene. HORST BRÜCKNER. Tech. Hochschule Dresden. *Z. angew. Chem.* 41, 955–6 (1928) — m -4-Xylydine and p -xylydine are sepd. successively as acetates from tech. xylydines, the m -2-, o -3- and o -4-isomers by means of H₂SO₄, each base being purified as formyl derivs. Waste xylydines, from which most of the m -4- and all the p -xylydine had been removed, gave 25% of m -4-, 21% of m -2-, 27% of o -3-, and 19% of o -4-xylydine. m -5-Xylenol is best prepd. from m -4-xylydine by acetylation, nitration, hydrolysis and diazotization, followed by treatment of the diazo compd. with NaOH and Zn(OH)₂, reduction of the 5-nitro- m -xylene so formed, diazotization and boiling with H₂O. Et-C₆H₄OH are conveniently obtained by ethylating C₆H₆ with C₂H₅I and AlCl₃, followed by nitration, reduction, diazotization and boiling with H₂O. C. J. WEST

Nitroarylsulfuric acids and their reduction products. GEORGE N. BURKHARDT AND HAROLD WOOD. Univ. of Manchester *J. Chem. Soc.* 1929, 141–52. — ClSO₃H (1.4 mols) was added to 3.7 mols. PhNMe₂ in 500 cc. CS₂ kept below 16°; to the mixt. heated to 35°, O₂NC₆H₄OH or O₂NC₁₀H₈OH (1 mol.) was added all at once; after stirring at 35° for 1 hr., the product was poured into dil. KOH; details for the sepn. of the K salts are given. *K o*-nitrophenyl sulfate, soly. in H₂O at 17° 6"; the p -isomer has the same soly.; *K 1*-nitro-2-naphthyl sulfate, pale yellow needles; the 4-nitro-1-naphthyl deriv. forms fine, pale yellow needles. These are all rapidly hydrolyzed by very dil. HCl at 70° and slowly at 100° by 10% Ba(OH)₂ or dil. AcOH contg. AcONa. Reduction with FeSO₄ in a suspension of CaCO₃ or BaCO₃ gives the corresponding NH₂ derivs., which give Ac and benzylidene derivs. without loss of the SO₄ group. *K o*-aminophenyl sulfate, gives with Br a faint violet color; the p -isomer crysts. with 1 H₂O, gives a violet color with Br and with HCl or AcOH and *H* deriv.; the *K benzylidene deriv.* crysts. with 0.5 H₂O. *K 1*-amino-2-naphthyl sulfate, crysts. with 0.5 H₂O; soly. in H₂O at 17° 1.1%; Br gives a dirty green ppt., changing to yellow with excess of Br; FeCl₃ gives an opalescence and then a blue ppt., which changes to brown; HCl or AcOH ppts. the *H* deriv., needles. p -H₂NC₆H₄SO₃H yields a diazo compd., which couples with m -C₆H₄(OH)₂, giving *K dihydroxybenzeneazophenyl sulfate*, orange plates with 1.5 H₂O; boiling with dil. HCl splits off the HSO₄ group; the 2-hydroxynaphthalene deriv., dark red, crysts. with 0.5 H₂O; ppts. are formed with BaCl₂, CaCl₂, HgNO₃ and MgSO₄. Results of dye tests with wool are given. The SO₄H group is removed when it is o - to the NH₂ group, but the diazo oxide results. Alk. reduction of o -O₂NC₆H₄SO₃K gives a mixt. of azo and hydrazo derivs. *K azobenzene 2,2'-disulfate*, orange plates with 0.5 H₂O, rapidly hydrolyzed at 70° by HCl. *K hydrazobenzene 2,2'-disulfate*,

needles; soly. in H_2O at 19° 3.2%, at 32° 5.4%; a satd. soln. at 20° with concd. HCl deposits 4,4'-diaminodiphenylene di- H 3,3'-disulfate, needles with 2.5 H_2O ; the K salt crystals with 1 H_2O ; characteristic reactions with Br and $FeCl_3$ are given. Diacetyl-dihydroxybenzidine, m. 292° (decompn.); heating at $300-20^\circ$ for 0.75 hr. gives the dianhydro deriv., m. $164-5^\circ$; the same compd. was prepd. from the sulfate.

C. J. WEST

Anisole. G. S. HIERS AND F. D. HAGER. *Org. Syntheses* 9, 12-4(1929).— $PhOH$ (235 g.) and 100 g. $NaOH$ in 1 l. H_2O , cooled below 10° , are treated with 315 g. Me_2SO_4 (during 1 hr.) and heated 0.5 hr.; then 235 g. $PhOH$ and 100 g. $NaOH$ are added and the mixt. is refluxed for 15 hrs. Yield of $PhOMe$: 72-5%; use of 0.5 this amt. of $PhOH$ gives a yield of 85-92%. $\beta-C_{10}H_7OMe$ was obtained in 65-73% yields.

C. J. WEST

Synthesis of polyphenol ketones. K. W. ROSENMUND AND HANS LOHFERT. Univ. Kiel. *Ber.* 61B, 2601-7(1928); cf. *C. A.* 22, 1579.—The observations that simple phenol ketones can be advantageously synthesized by the Friedel-Crafts reaction as modified by Behn and that the rearrangement of phenol esters into phenol ketones by means of $AlCl_3$ can likewise be smoothly effected in $PhNO_2$ have been utilized in the synthesis of polyphenol ketones. Thus, 4-chloroacetopyrocatechol is obtained in 60% yield by heating $o-HOC_6H_4O_2CCH_2Cl$ 15 mins. with $AlCl_3$ in $PhNO_2$. The simple pyrocatechol ketones can be prepd. in 3 ways: (1) $C_6H_4(OH)_2$ and $AlCl_3$ in hot $PhNO_2$ are treated with 1 equiv. acid chloride; (2) the di-esters of $C_6H_4(OH)_2$ are rearranged in hot $PhNO_2$ with $AlCl_3$, one acyl radical migrating to the nucleus and the other being split off; (3) the same as (2) except that an extra mol. of $C_6H_4(OH)_2$ is added and this reacts with the acyl group split off from the other mol. of $C_6H_4(OH)_2$ to form a 2nd mol. of ketone. In general, the best yields are obtained by heating 2 hrs. at 75° . Below are the yields (%) obtained by the 3 methods, resp.: 4-acetopyrocatechol, 34.0, 46.6, 88.0; 4-butyropyrocatechol (II), 27.0, 35.0, 70.0; quinacetophenone, 40, 23, 54; quinopropylphenone, 40, 34, 61. The phloroglucinol ketones are prepd. by allowing the $C_6H_3(OH)_3$ and $AlCl_3$ to react with each other in $PhNO_2$ until a complex has been formed and soln. is complete before adding the acid chloride. Pyrocatechol dipropionate, from $C_6H_4(OH)_2$ and $EtCOCl$ on the H_2O bath, b_{14} $153-7^\circ$, b_{160} 281° . Propionylpyrocatechol (39% from the preceding compd.), yellow, m. 146° . II, m. 146° . Pyrocatechol diisovalerate (yield, 70%), thick oil, b. $153-73^\circ$ in vacuo; isovaleropyrocatechol (yield, 40%), m. 108° . Pyrocatechol distearate, m. $83-5^\circ$; stearopyrocatechol, m. 70° . 3,4-(HO) $_2C_6H_3Bz$, m. 134° , is obtained almost quant. from $C_6H_4(OBz)_2$. Phlorobutyphenone, needles with 1 H_2O , m. $179-80^\circ$, was obtained in 2.7-3.4 g. yield from 3.5 g. $C_6H_3(OH)_3$; phlorocapronophenone, m. 100° (hydrated), 120° (anhyd.), in 63% yield; phloroisovalerophenone, m. 145° , was similarly prepd. Tribenzoylphloroglucinol (30% from $C_6H_3(OBz)_3$ and $AlCl_3$ at $130-40^\circ$), m. 185° .

C. A. R.

Synthesis of naringenin and phloretin. K. W. ROSENMUND AND MARGARETHE ROSENMUND. Univ. Kiel. *Ber.* 61B, 2608-12(1928); cf. preceding abstr.—Having found that their new method of synthesizing phloroglucinol ketones can be used for the prepn. of aromatic and aliphatic-aromatic ketones also, R. and R. undertook the synthesis of naringenin (I), at the time thought to have the chalcone structure $(HO)_3C_6H_2COCH:CHC_6H_4OH$ (II); Fischer from $PhCH:CHCN$ and $C_6H_3(OH)_3$ under the conditions of the Hoesch ketone synthesis had obtained, not the expected chalcone but the isomeric hydrocoumarin $(HO)_3C_6H_2.CHPh.CH_2.CO.O$ (III). By allowing

$PhCH:CHCOCl$ to stand several days below 20° in $PhNO_2$ with the complex from $C_6H_3(OH)_3$ and $AlCl_3$, R. and R. obtained, together with much resinous products, 2 cryst. compds. (IV and V). IV, $C_{18}H_{12}O_4$, m. 202° , depressed the m. p. (211°) of F.'s III to 176° and gave a strong $FeCl_3$ reaction (red-violet-brown). The compd. V, red-brown crystals, m. 210° , was not further studied because of the small quantity available. p -Carbomethoxycoumaryl chloride under the same conditions likewise gave 2 compds. $C_{17}H_{14}O_7$ (VI and VII). Elimination of the CO_2Me group from VII yielded I. At this time appeared the paper of Asahina and Inubuse (*C. A.* 22, 4526) showing that natural I is a flavanone, $(HO)_3C_6H_2.O.CH(C_6H_4OH).CH_2.CO$ (VIII),

and as IV and VII give the flavanone reactions described by A. (red color on reduction with Mg and HCl) their flavanone structure is proved, leaving the chalcone structure for VI and (presumably) V, i. e., in R. and R.'s expt. most of the II isomerized into VIII. The di-Me ether of the synthetic I m. $115-6^\circ$ (A. gives $116-7^\circ$ for the ether of natural I (sakuranetin Me ether)) but contrary to A.'s observation synthetic I can

be reduced catalytically with rupture of the ring and formation of phloretin. After this work had been presented in Sept., 1928, before the Naturforscher-Versammlung at Hamburg there appeared in the *Chem. Zentr.* an abstr. of the paper of Shinoda and Sato (*J. Pharm. Soc. Japan* 48, 109), who prepd. a no. of phloroglucinol ketones and flavanones by apparently the same methods. Benzophloroglucinol, m. 165°, was obtained in 1.7 g. yield from 2 g. $C_6H_5(OH)_2$ and $AlCl_3$ in $PhNO_2$ with $BzCl$. Phenylacetophloroglucinol, from $PhCH_2COCl$, m. 164-6°, gives a red-violet color with $FeCl_3$. Anisoylphloroglucinol, yellow, m. 177-8°, gives a red-violet color with $FeCl_3$. Dihydrocinnamoylphloroglucinol, yellow, m. 137-8°. [*p'*-Carbomethoxyoxy]benzophloroglucinol, 2,4,6-(HO), $C_6H_5COC_6H_4OCOC_2H_5$, from *p*- $EtO_2COC_6H_4COCl$, yellow, m. 172°. 5,7-Dihydroxyflavanone (IV), yellowish white. 4'-[Carbomethoxyoxy]-2,4,6-trihydroxychalcone (VI), yellow, m. 166°. 4'-[Carbomethoxyoxy]-5,7-dihydroxyflavanone (isopmethoxynaringenin) (VII), m. 183-4°. C. A. R.

The action of ethylamine and diethylamine upon the oxide of isosafrole. T. S. KUSNER. *J. Russ. Phys.-Chem. Soc.* 60, 655-9 (1928).—The NH_2Et deriv. of isosafrole oxide, $CH_3O_2C_6H_4CH(OH)CHMeNH_2$, was obtained by adding 7 g. of $EtNH_2$ in a mixt. of 1 part of alc. and 2 parts of water to 9 g. of isosafrole oxide and allowing the mixt. to stand for 3 days at 35°-40°, after which the reaction mass was freed from alc. and water by evapg. on the water bath. The resulting brown liquid, after drying over $CaCl_2$, was subjected to fractional distn., the fraction b_m 175-180° yielded 9 g. of a colorless, viscous liquid, which on standing solidified to an oily cryst. mass, and on recrystn. from ligroin produced needle-like crystals, m. 67°. The substance is readily sol. in alc., Et_2O , acetone, $AcOEt$, and sparingly sol. in water with alk. reaction. The HCl salt was obtained by conducting dry HCl gas into the soln. of the amino alc. in dry Et_2O ; the ppt. of the HCl salt is not hygroscopic, and is easily sol. in water. When recrystd. from alc. it m. 181°. The picrate, obtained by mixing alc. solns. of equimol. proportions of picric acid and the amino alc., and recrystg. from $AcOEt$, m. 168-9°. The diethylamine deriv. of isosafrole oxide, $CH_3O_2C_6H_4CH(OH)CHMeNEt_2$ was obtained by heating a mixt. of 7 g. of isosafrole oxide, 3 g. of NH_4Et , 3 g. of alc. and 3 g. of water in a sealed glass tube for 4 hrs. in a water bath. The reaction mass was removed from the tube and treated on the water bath to expel water and alc., after which it was dried over $CaCl_2$, twice fractionated, and the fraction b_m 174-8° was collected, yielding 6 g. of a mobile almost colorless liquid having an NH_2 odor and alk. reaction, and sol. in Et_2O , alc. and acetone. The HCl salt, m. 196-7°, and the picrate, m. 160°, were obtained by the same method as described above. CHAS. BLANC.

The ultra-violet absorption spectra curves of isoeugenol and of eugenol. J. SAVARD. *Bull. soc. chim.* [4], 43, No. 10, 1072-5 (1928); cf. C. A. 22, 3157.—The ultra violet absorption curve for eugenol gives a max. (A) at $\lambda = 2807$, and another (B) at about $\lambda = 2300$. It shortly bends again and continues upward thereafter. Isoeugenol gives a somewhat similarly shaped curve with a max. (A) at $\lambda = 2925$, another at (B) $\lambda = 2565$, after bending downward it then continues upward to the end. When an allyl chain is replaced by a propenyl one, thereby bringing the C:C group nearer the nucleus, the max. (A) is displaced toward the red about 120° A. U. (B) is likewise shifted, but to a greater extent, i. e., 280 A. U. (A) is probably due to the phenolic ether function and (B) to the C:C group. The curve for veratrole is similar in shape to, and near that of eugenol. When in veratrole a β, γ -C:C side chain is introduced, no notable change in the curve results; when the new C:C group is conjugated with the aromatic nucleus, and hence is in the α, β -position the curve is shifted toward the red. G. ALBERT HILL.

Phloroglucinol. H. T. CLARKE AND W. H. HARTMAN. *Org. Syntheses* 9, 74-6 (1929).—Details are given of the reduction of 2,4,6-(O_2N), $C_6H_2CO_2H$ with Sn and HCl to the tri- NH_2 deriv., which is then hydrolyzed by boiling H_2O , giving 46.5% of $C_6H_3(OH)_3 \cdot 2H_2O$. C. J. WEST.

γ -Phenoxypropyl bromide. C. S. MARVEL AND A. L. TANENBAUM. *Org. Syntheses* 9, 72-3 (1929).—Details are given of the reaction of $PhONa$ and $(CH_2)_3Br$, which gives 84-8% of $PhO(CH_2)_3Br$ (cf. C. A. 17, 260). C. J. WEST.

Dehydration of benzyl alcohol by phosphoric anhydride in presence of benzene. S. S. NAMETKIN AND D. N. KURBANOV. *J. Russ. Phys.-Chem. Soc., Chem. Pt.* 60, 917-20 (1928).—Nef has pointed out (cf. *Ann.* 298, 254 (1897)) that in the action of P_2O_5 on $PhCH_2OH$ in presence of C_6H_6 , dehydration of the alc. does not take place and CH_2Ph_2 is obtained. In repeating the expt., N. and K., after careful fractionation of the products of reaction, found that *p*- $C_6H_4(CH_2Ph)_2$ has been formed together with Ph_2CH_2 . The formation of the former substance apparently takes place in 2 stages: at first the alc. condenses with C_6H_6 , then the latter condenses with a 2nd mol.

of the alc.: $\text{CH}_3\text{Ph}_2 + \text{HOCH}_2\text{Ph} = \text{H}_2\text{O} + \text{C}_6\text{H}_4(\text{CH}_2\text{Ph})_2$. After driving off C_6H_6 , the distn. under 11 mm. of the products of reaction yields 2 fractions: 128–9° (22 g.) and 210–8° (12 g.); the 1st consists of CH_3Ph_2 , the 2nd is composed of $\text{C}_6\text{H}_4(\text{CH}_2\text{Ph})_2$. The residue is a thick, tarry substance which has not been examd. B. N.

***o*-Aminobenzyl alcohol.** ARNOLD REISSERT AND KARL CRÄMER. Univ. Marburg. Ber. 61B, 2555–66(1928).—Reduction of *o*- $\text{O}_2\text{NC}_6\text{H}_4\text{CH}_2\text{OH}$ with all of the usual reducing agents proved unsatisfactory for the prepn. of *o*- $\text{H}_2\text{NC}_6\text{H}_4\text{CH}_2\text{OH}$ (I), but 91–2% of crude and 88% perfectly pure I was obtained with NaSH , although according to Ger. pats. 99,542 and 106,509 *o*- and *p*- $\text{O}_2\text{NC}_6\text{H}_4\text{CH}_2\text{OH}$ and related compds. are converted by alkali sulfides into the corresponding amino aldehydes. The diazonium salts of I are extraordinarily labile. The diazotized HCl soln. decomp. so rapidly at 0° that in 3 hrs. the decompn. into N_2 and saligenin (II) is complete. The coupling of diazotized I with resorcinol and the naphthols (Paal and Senninger) has been in part repeated and coupling with *p*- $\text{MeC}_6\text{H}_4\text{NH}_2$, 2- $\text{C}_{10}\text{H}_7\text{NH}_2$ and 2,3- $\text{C}_{10}\text{H}_6(\text{OH})\text{CO}_2\text{H}$ has also been effected; PhOH and *o*- $\text{HOC}_6\text{H}_4\text{CO}_2\text{H}$ gave no products which could be purified. Of these azo dyes, those contg. only C_6H_5 nuclei are not anhydridized by concd. H_2SO_4 to compds. contg. the N:N group in an 8-membered ring but the dye from 2- $\text{C}_{10}\text{H}_7\text{NH}_2$ readily undergoes such a dehydration and those from 2- $\text{C}_{10}\text{H}_7\text{OH}$ and $\text{C}_{10}\text{H}_6(\text{OH})\text{CO}_2\text{H}$ yield SO_2H acids of the anhydro dye. Diazotized I gives by the Leuckart xanthate method a mixt. of xanthic esters with II. With Na_2S was obtained a mixt. of 13% (*o*- $\text{HOCH}_2\text{C}_6\text{H}_4$) $_2\text{S}$ (III), 17% II and 60% *o*- $\text{HSC}_6\text{H}_4\text{CH}_2\text{OH}$ (IV). The diazonium chloride cautiously treated with Na_2S_2 forms smoothly and in good yield an explosive compd. which with boiling H_2O gives ($\text{HOCH}_2\text{C}_6\text{H}_4$) $_2\text{S}_2$ (V); if the reaction is carried out in the presence of NaOH the primary diazo compd. decomp. at room temp. with a uniform evolution of N_2 . Zn dust and NaOH reduce V to IV. V never gave $\text{HOCH}_2\text{C}_6\text{H}_4\text{SCl}$ by the Zincke method, even in non-dissociating solvents; there was always formed the nucleus-chlorinated *o*- $\text{HOCH}_2\text{C}_6\text{H}_4\text{ClSO}_2\text{Cl}$ (VI). The nature of the solvent influenced only the yield of VI (almost quant. with AcOH , only 30–5% with CHCl_3). NH_3 in Et_2O not only replaces the Cl in the SO_2Cl group of VI but also splits off H_2O , giving 83% of the compd. $\text{ClC}_6\text{H}_4\text{CH}_2\text{NH}\cdot\text{SO}_2$ (VII).

PhNH_2 , on the other hand, gives the normal sulfonanilide (VIII), which with hot NaOH loses H_2O to form *N*-phenyl-*bz*-chlorobenzyl alc. sulfinide (IX), oxidized by HNO_3 or CrO_3 to the intensely sweet chlorobenzoic sulfinide, $\text{ClC}_6\text{H}_4\text{CO}\cdot\text{NH}\cdot\text{SO}_2$ (X), which is different

from the known 4- and 6-chlorosaccharins and which must, therefore, be the 3- or 5-deriv. Attempts to establish the position of the Cl atom by oxidation of VI or rupture of the ring in X and subsequent elimination of CO_2 gave only viscous oils. Cautious fusion of VI with KOH gave in very small yield a chloro-2-hydroxybenzyl alc. (XI) different from the 5- Cl compd. and X yielded a chlorosalicylic acid (XII) different from the 5- Cl acid. VI, VII and X can, therefore, contain the Cl atom only in the *o*-position to the S. In harmony with this structure is the fact that VI offers such resistance to hydrolysis that it can be distd. unchanged with steam. Attempts to prep. *o*- $\text{HONHC}_6\text{H}_4\text{CH}_2\text{OH}$ (XIII) by the Bamberger method gave a compd. XIV having the compn. of a mol. compd. of 1 mol. each of XIII and the azoxy alc. (XV) and quickly changing in the air into XV. XIV was also obtained by fusing together equimol. quantities of XIII and XV but 3 months later when it was again attempted to prep. XIV only XIII could be obtained. *p*-Toluenediazo-*o*-aminobenzyl alc., from diazotized I and *p*- $\text{MeC}_6\text{H}_4\text{NH}_2$ in AcOH with NaOAc , yellow, m. 108–9°, insol. in dil. acids and alkalies, easily sol. in concd. acids, converted by *p*- $\text{MeC}_6\text{H}_4\text{NH}_2$ and its HCl salt in hot H_2O into *p*-toluidine-*o*-azobenzyl alc., m. 112–3°, easily sol. in dil. acids. With *m*- $\text{C}_6\text{H}_4(\text{OH})_2$ in the calcd. quantity of NaOH diazotized I gives (HO) $_2\text{C}_6\text{H}_3\text{N}:\text{NC}_6\text{H}_4\text{CH}_2\text{OH}$ in deep red crystals with 1 H_2O , m. 159–60° and, after dehydration at 150°, m. 180–1° (Paal and Senninger describe it as anhyd. red-brown needles with metallic luster, m. 170°). β -Naphthol-*o*-azobenzyl alc., dark red, m. 185°, converted by concd. H_2SO_4 at 70° into anhydro- β -naphtholsulfonic-*o*-azobenzyl alc., $\text{HO}_2\text{SC}_{10}\text{H}_7\text{O}\cdot\text{CH}_2\cdot\text{C}_6\text{H}_4\text{N}:\text{N}$, m. above

300°. β -Naphthylamine-*o*-azobenzyl alc., orange-red, m. 150–1°, insol. in dil. acids, sol. in concd. H_2SO_4 with blue, in alc. and Et_2O with dark red color; anhydro deriv., light brown, m. 161°. 2,3-Hydroxynaphthoic-*o*-azobenzyl alc., m. 214–6°, easily sol. in alkalies, insol. in acids. Anhydro-2,3-hydroxynaphthoic-sulfonic-*o*-azobenzyl alc., m. above 320°. Et [*o*-hydroxymethylphenyl]xanthate (obtained through a yellowish cryst. intermediate product, probably the diazo compd., $\text{HOCH}_2\text{C}_6\text{H}_4\text{N}_2\text{SCSOEt}$, which decomp. explosively at 3°), oil which decomp. on distn. *o*-Mercaptobenzyl

alc. (IV), obtained from the above xanthate with boiling alc. KOH and isolated as the yellow to orange-red *Pb* salt; benzoate, m. 125–6°, insol. in alkalis and cannot be oxidized to the disulfide, indicating that the Bz group is on the S, not the O, mol. wt. in camphor 250.6. *o*-Benzyl alc. disulfide (bis-[*o*-hydroxymethylphenyl] disulfide) (V), from IV with FeCl_3 or H_2O_2 , m. 144°, is obtained in better yield (73%) from diazotized I and Na_2S_2 . *o*-Benzyl alc. sulfide (bis-[*o*-hydroxymethylphenyl] sulfide) (III), yellow, m. 164°. 1-Hydroxymethyl-3-chlorobenzene-2-sulfonyl chloride (VI), m. 62°, mol. wt. (Rast) 239, easily sapond. by boiling dil. NaOH, but stable toward steam even in 60% H_2SO_4 . 7-Chlorobenzyl alc. sulfinide (VII), m. 158°, easily sol. in NaOH, mol. wt. (Rast) 209.4, gives in NaOH with Me_2SO , the 2-Me deriv., m. 127°. VIII, m. 94°, mol. wt. (Rast) 294. 2-Ph deriv. (IX) of VII, m. 151°, insol. in alkalis and unchanged on boiling, mol. wt. (Rast) 271. X, m. 153.5°. 3-Chlorosaligenin (XI), m. 116°, gives a blue-violet color with FeCl_3 . XII, m. 170°, gives a red-violet color with FeCl_3 . XIV, m. 84°, sol. in dil. HCl, NaOH pptg. XV, m. 123°, from the soln.

C. A. R.

p-Methoxycinnamyl alcohol. P. KARRER. *Helv. Chim. Acta* 11, No. 6, 1209 (1928).—*p*-Methoxycinnamyl alc., reported as m. 73°, m. 79–80° when pure.

G. ALBERT HILL

The use of zirconium tetrachloride in organic synthesis. P. KRISHNAMURTI. *J. of Madras Univ.* 1928, 5 pp. (reprint).—Anhyd. ZrCl_4 , prepd. by passing Cl mixed with CCl_4 over strongly heated zirconia, resembles AlCl_3 in its phys. and chem. properties and can be used in Friedel-Crafts reactions. 65–70% of PhCOMe and 75% Ph_2CO were obtained from the acid chlorides and ZrCl_4 in dry C_6H_6 by the usual method. By the modified Gatterman synthesis, a poor yield of $\text{MeOC}_6\text{H}_4\text{CHO}$ was obtained from PhOMe, $\text{Zr}(\text{CN})_2$ and ZrCl_4 in dry C_6H_6 . Ph_3CH was obtained in poor yield from CHCl_3 . With PhCH_2Cl in C_6H_6 a mixt. of hydrocarbons was obtained from which 30% Ph_3CH_2 was isolated. 25% phenolphthalein was prepd. from $\text{C}_6\text{H}_5(\text{CO})_2\text{O}$ and PhOH. A theoretical yield of PhOH from PhOMe was obtained. PhNCO and C_6H_5 with ZrCl_4 gave PhNHCOPh. With PhMe, PhNCO gave *p*- $\text{MeC}_6\text{H}_4\text{CONHPh}$. *p*- $\text{C}_6\text{H}_4\text{Me}_2$ and PhNCO gave *p*- $\text{Me}_2\text{C}_6\text{H}_3\text{CONHPh}$. $\text{C}_6\text{H}_5\text{Me}_2$ and PhNCO gave $\text{Me}_2\text{C}_6\text{H}_3\text{CONHPh}$. With PhCl the yield of the anilide was very poor. PhCOMe and PhNCO gave $\text{MeOC}_6\text{H}_4\text{CONHPh}$. PhNCO would not react with PhNO_2 and PhCOMe. Since large quantities of the mineral Baddeleyite (ZrO_2) occur in Brazil and Ceylon, the use of ZrCl_4 as a lab. reagent is predicted. R. C. ROBERTS

p-Bromophenacyl bromide. W. D. LANGLEY. *Org. Syntheses* 9, 20–1 (1929)—*p*- $\text{BrC}_6\text{H}_4\text{Ac}$ (50 g.) in 100 cc. glacial AcOH, slowly treated at 20° with 40 g. Br (30 mins.), gives 69–72% of *p*- $\text{BrC}_6\text{H}_4\text{COCH}_2\text{Br}$.

C. J. WEST

o-Chlorobenzoyl chloride. H. T. CLARKE AND E. R. TAYLOR. *Org. Syntheses* 9, 34–5 (1929).—Directions are given for the chlorination of *o*- $\text{ClC}_6\text{H}_4\text{CHO}$ at 150–60° (Cl absorption complete after 15 hrs.); distn. gives 70–2% of *o*- $\text{ClC}_6\text{H}_4\text{COCl}$, b_{10} 93–5°, b_{76} 137–9°. With 2665 g. $\text{ClC}_6\text{H}_4\text{CHO}$, the yield was 81%. At 125–40°, the reaction requires about 30 hrs. for completion.

C. J. WEST

A case of the isomorphous replacement of the chlorine atom by the hydroxyl group in organic compounds. VICTOR VILLIGER. I.-G. Farbenindustrie Aktiengesell., Ludwigshafen a. Rh. *Ber.* 61B, 2596–9 (1928).—In attempts to prep. 2,4,5- $\text{Cl}(\text{HO})(\text{O}_2\text{N})\text{C}_6\text{H}_2\text{CO}_2\text{H}$ (I) by treating $\text{Cl}_2(\text{O}_2\text{N})\text{C}_6\text{H}_2\text{CO}_2\text{H}$ (II) with alkalis it was found that when the reaction had not gone to completion there were obtained products which, although apparently homogeneous (homogeneous cryst. form, sharp m. p.), were mixts. of I and II whose m. ps. lay between those of the I and II and which did not depress the m. p. of the lower melting I (161–3.5°). A 1:1 mixt. of the 2 compds. (II m. 202–4°) m. 183–6°, a 2:1 mixt. m. 174–6°. Grimm has undertaken the further study of this case of isomorphism and will report on it elsewhere. The I is prepd. by converting *p*- $\text{MeC}_6\text{H}_4\text{SO}_2\text{Cl}$ with Cl and SbCl_5 into 4,3- $\text{MeClC}_6\text{H}_3\text{SO}_2\text{Cl}$, chlorinating this at 150–200° in the absence of all metals, treating the resulting 2,4- $\text{Cl}_2\text{C}_6\text{H}_3\text{CCl}$ with concd. H_2SO_4 and nitrating the 2,4- $\text{Cl}_2\text{C}_6\text{H}_3\text{CO}_2\text{H}$ thus obtained. I is purified through the Ca, II through the red Ba salt, and mixts. of the II are sep'd. by means of the latter salt.

C. A. R.

Stovaine. I. RIBAS AND A. RANCAÑO. *Anales soc. españ. fis. quim.* 26, 430–4 (1928).—The apparently racemic stovaine has been found to be truly racemic by the Bakhuis Roozeboom criteria. By the van't Hoff dilatometric method the racemic form is stable from –10° to 175°, its m. p.

E. M. SYMMES

Acid ammonium *o*-sulfobenzoate. H. T. CLARKE AND E. E. DREGER. *Org. Syntheses* 9, 1–2 (1929).—Saccharin (188 g.) is heated with 565 cc. H_2O and 188 g. concd. HCl for 2.5–3 hrs. (soln. results); 188 g. of saccharin is again added and the

heating continued for 1.5–2 hrs.; on concg. the soln., 91–5% of $\text{HO}_2\text{CC}_6\text{H}_4\text{SO}_2\text{NH}_4$ is obtained. Recrystn. from an equal wt. of H_2O gives 90% of a purer product.

C. J. WEST

***o*-Sulfobenzoic anhydride.** H. T. CLARKE AND E. E. DREGER. *Org. Syntheses* 9, 80–2(1929).—*o*- $\text{HO}_2\text{CC}_6\text{H}_4\text{SO}_2\text{NH}_4$ (219 g.) and 200 cc. dry C_6H_6 , treated with 145 g. SOCl_2 , give 64–6% of *o*-sulfobenzoic anhydride; with larger quantities the yields are significantly increased.

C. J. WEST

Phenylsuccinic acid series. IX. Resolution of *dl*-diphenylsuccin- α - and β -naphthylamic acids into their optical antipodes. HENRY WREN AND EDWARD WRIGHT. Municipal College of Tech., Belfast. *J. Chem. Soc.* 1929, 136–8; cf. *C. A.* 19, 265.—*dl*-Diphenylsuccinic anhydride and α - $\text{C}_{10}\text{H}_7\text{NH}_2$ give *dl*-diphenylsuccin- α -naphthylamic acid, m. 217–9°, the quinine salt, repeatedly recrystd. from EtOH, gives the *d*-acid, m. 206–7°, $[\alpha]_D^{16}$ 205.8° (Me_2CO , *c* 0.8432); the sol. portion of the quinine salts, transformed into the cinchonidine salt, yields the *l*-acid, m. 206–7°, $[\alpha]_D^{17}$ –206.6° (Me_2CO , *c* 0.9484). Boiling 3% EtOH-HCl transforms the *d*-acid into *d*-diphenylsuccin- α -naphthil, m. 145°, $[\alpha]_D^{16}$ 139.2° (Me_2CO , *c* 1.0916), $[\alpha]_D^{17}$ 123.3° (CHCl_3 , *c* 1.2608); this is unusually readily racemized by EtONa in EtOH; crystn. from EtOH occasionally caused complete racemization; this was avoided by using EtOH contg. a trace of HCl. *dl*-Diphenylsuccin- β -naphthylamic acid, m. 201–2°, was also resolved by quinine; the *d*-acid, m. 188°, $[\alpha]_D^{16}$ 386.9° (Me_2CO *c* 0.7288); the *l*-acid could not be obtained pure. *d*-Diphenylsuccin- β -naphthil, m. 178–9°, $[\alpha]_D^{18}$ 104.9° (Me_2CO , *c* 0.8792). **X. Racemization phenomena observed during the action of water and bases on the optically active diphenylsuccinic anhydrides.** *Ibid* 138–41.—The production of substituted amic acids from the active anhydrides and PhNH_2 , *p*- $\text{MeC}_6\text{H}_4\text{NH}_2$, α - or β - $\text{C}_{10}\text{H}_7\text{NH}_2$ in the presence of cold C_6H_6 is accompanied by not more than slight, if any, racemization; *l*-diphenylsuccin- β -naphthylamic acid, m. 188–8.5°, $[\alpha]_D^{17.5}$ –388.2° (Me_2CO , *c* 0.7355). Interaction of H_2O and *d*-diphenylsuccinic anhydride in the presence of Me_2CO (20 cc. Me_2CO and 5 cc. H_2O) gives a product with 4.5% meso-acid; in $\text{C}_6\text{H}_6\text{N}$, 3.4%; in Et_2O , 2.8%; in AcOH, 3.6%. From the *dl*-anhydride, the % of meso-acid obtained by use of aq. Me_2CO , $\text{C}_6\text{H}_6\text{N}$ and Et_2O was 2.0, 2.0 and 1.0, resp. With AcOH the av. value (3 expts.) was 21%.

C. J. WEST

Hydrocinnamic acid. A. W. INGERSOLL. *Org. Syntheses* 9, 42–5(1929).—Details of the app. for and method of the electrolytic reduction of $\text{PhCH}_2\text{CH}_2\text{OH}$ to $\text{PhCH}_2\text{CH}_2\text{CO}_2\text{H}$ are given. The yields are 80–90%, depending upon the quality of acid used; a technical acid gave only 60% yield. By the same process β -furylacrylic was reduced, giving 60–70% of β -furylpropionic acid.

C. J. WEST

Carbonylbisamino acids and their transformation products. II. FRITZ WESSELY AND JOSEF MAYER. Univ. Wien. *Monatsh.* 50, 439–48(1928); cf. *C. A.* 22, 409.—(+)-*Et* carbonylbis- α -amino- β -phenylpropionate (I), $\text{CO}[\text{NHCH}(\text{CO}_2\text{Et})\text{CH}_2\text{Ph}]_2$, m. 142.5° (cor.), $[\alpha]_D^{16}$ 42.28° (EtOH), prepd. by the action of COCl_2 on (–)- $\text{PhCH}_2\text{CH}(\text{NH}_2)\text{CO}_2\text{Et}$, is converted by heating with HCl and AcOH into (–)- α -[5-benzyl-3-hydantoin]- β -phenylpropionic acid (II), m. 205.5°, $[\alpha]_D^{15}$ –210.7° (EtOH). The (–)-*Et* ester (III) corresponding to I, m. 142.5° (cor.), $[\alpha]_D^{15}$ –42.35° (EtOH), from (+)- $\text{PhCH}_2\text{CH}(\text{NH}_2)\text{CO}_2\text{Et}$, yields the (+)-acid (IV) corresponding to II, m. 205.5°, $[\alpha]_D^{15}$ 211° (EtOH). Equimol. mixts. of I and III and of II and IV, m. 144.5° (cor.) and 229.5°. While the *dl*-carbonylbisphenylalanines (V) previously described are unaffected by heating with 1 or 2 mols. *N* NaOH, the corresponding esters, m. 145° and 141.5°, resp., both yield a mixt. of the 2 *dl*-acids on hydrolysis with 2 mols. of alkali. With 1 mol. of alkali the former ester gives a mixt. of the 2 isomeric α -[5-benzyl-3-hydantoin]- β -phenylpropionic acids, m. 229° and 171°, resp., while the latter ester affords only the form m. 229°. The hydantoin deriv., m. 171°, is converted into its isomer, m. 229°, by treatment with 1 mol. of alkali, and both of these compds. are hydrolyzed by 2 mols. of alkali, forming the same mixt. of V. *Et* α -[5-benzyl-3-hydantoin]- β -phenylpropionate, m. 130° (cor.), is obtained by the action of MeCHN_2 on the corresponding acid, m. 171–2°, crysts. with 1.5 H_2O . (With E. KEMM.) Hydrolysis of *Et* carbonylbisaminoacetate with MeOH-KOH gives a mixt. of hydantoin-3-acetic acid and carbonylbisaminoacetic acid.

C. J. WEST

Esterification of aromatic and olefinic nitriles. P. PFEIFFER, ERMA ENGELHARDT AND WILLY ALFUSS. Univ. Bonn. *Ann.* 467, 158–90(1928).—A single *o*-substituent inhibits practically completely the conversion of an aromatic nitrile into a carboxylic ester by heating it with MeOH - or EtOH-HCl ; the chem. nature of the substituent

plays a minor part, for the Me, NO₂, Cl, Ph and vinyl groups all act the same way. The rule is similar to that which applies to the formation of imino ethers. Acting on the assumption that aromatic nitriles may be considered as a special class of olefinic nitriles, a no. of α -substituted PhCH:CHCN were examd. By starting with the *cis*- and *trans*-acids, dehydration of the amides gave the corresponding nitriles. The *trans*-compds. were in all cases easily esterified but the *cis*-compds. were esterified not at all or only very slowly under the usual conditions. This corresponds with the similarity of the configurations of the *cis*-compds. and *o*-substituted aromatic nitriles. Ease or difficulty of esterification is, in the absence of other evidence, indicative of *trans*- or *cis*-configuration, resp. While 4-Me₂NC₆H₄CH:CHPh, the 4'-NO₂ deriv. and the 4',2'-O₂N(NC) derivs. and the amide, acid and ester corresponding with the last are fluorescent, transposition of the NO₂ and CN groups yields a nonfluorescent compd. 2,4-O₂N(NC)C₆H₃CH:CHC₆H₄(NMe)₂-4 and the corresponding Me and Et esters are likewise nonfluorescent. The esterification of the nitriles was carried out by refluxing with 40 parts of anhyd. alc. for 2 hrs., while a stream of HCl was passed in the soln., and the amt. of ester in the washed product was detd. from the % of N. The following figures give the % of Me or Et esters, resp., found in the product; when only 1 figure is given, it refers to the Me ester. PhCN, 65.4, 35.1; MeC₆H₄CN, *o*-, 0, 0; *m*-, 92.1, 58.7; *p*-, 83, 80; O₂NC₆H₄CN, *o*-, 0, 0; *m*-, 87, 45; *p*-, both high, 2,3-Me(O₂N)C₆H₃CN, 0; 4,3-Me(O₂N)C₆H₃CN, high; ClC₆H₄CN, *o*-, 0, 0; *p*-, 97, 67.9; *o*-phenylbenzonitrile, b₁₆ 176-7°, obtained from the acid amide in 35% yield, 8.4, 5.6; *p*-PhC₆H₄CN, 82, 70.4; C₁₀H₇CN, α -, 0, 0; β -, 77.1, 77; 4',2',4-O₂N(NC)C₆H₃CH:CHC₆H₄NMe₂, 0; *p*-Me₂NC₆H₄CHO and 2,4-Me(O₂N)C₆H₃CONH₂, heated with a little piperidine at 120-30° for 1.5 hrs., give *p*-nitro-*p'*-dimethylaminostilbene-*o*-carboxylic amide, m. 242-3° (decompn.), which, heated 3 hrs. with 25% HCl, gives the free acid, m. 206° (decompn.); Me ester, m. 158-9°; Et ester, m. 139-40°. PhCH:CHCN, 96.2, 85; α -methylcinnamonitrile, b₁₆ 120°, 69.8, 36.8; *cis*- α -chlorocinnamonitrile, b₁₆ 128°, m. 19-21° (53% yield from the amide); *trans*-deriv., b₁₇ 138-9°, m. 34° (35% yield); both were esterified readily but inversion of the *cis*-form occurred, for the *trans*-ester was formed in each case. *cis*-PhCH:C(CN)Ph is not esterified. *trans*- α -Phenylcinnamonitrile, m. 49-51° (72% yield), gives 39 of the Me ester. *cis*- α -Phenyl-*m*-nitrocinnamoyl chloride, m. 101° (94% yield); amide, yellow, m. 176-80° (yield); nitrile, m. 133-4° (70% yield); this is not esterified with MeOH-HCl. The *trans*-chloride, m. 93° (94% yield); amide, m. 146° (78% yield); nitrile, m. 96 (68% yield); MeOH-HCl gives 51% ester. *cis*-PhCH:C(*p*-C₆H₄NO₂)C₆H₄ crystals with 1 H₂O, canary-yellow, and also with 0.5 mol. C₆H₆, m. 100-20°; the chloride, m. 88-91.5° (95% yield); amide, yellow, m. 208.5-10° (65% yield); nitrile, m. 121-2°, light yellow, 70% yield; it is not esterified. The *trans*-chloride, yellow, m. 95° (95% yield); amide, m. 183-4° (77% yield); nitrile, m. 183-4° (77% yield); MeOH-HCl gives 48% ester. The *cis*- and *trans*-Me₂NC₆H₄CH:C(*p*-C₆H₄NO₂)CONH₂ give on hydration the same *cis*-nitrile, m. 241-2°, which could not be esterified. Dibenzalpropionyl chloride, liquid, amide, m. 178-9°; *cis*-nitrile, m. 115-6°; neither MeOH nor EtOH esterifies the nitrile. *cis*-PhCH:C(C₆H₄SO₃H)CN is not esterifiable. α -Phenylcrotonic acid yields an amide, m. 98-9°, and the *cis*-nitrile, b₁₂₋₁₄ 125°; the % of esterification were 9.6 and 7.9. An attempt to prep. the nitrile by condensation of PhCH₂CN with paraldehyde was unsuccessful. PhCH₂CHPhCN is readily esterified (64% yield). C. J. WEST

Ethyl cinnamate. C. S. MARVEL AND W. B. KING. *Org. Syntheses* 9, 38-40 (1929).—Directions are given for the condensation of BrH and AcOEt by Na, with the formation of 68-74% of PhCH:CHCO₂Et; the AcOEt should be specially purified. C. J. WEST

Synthesis of isobipanic acid. SATYENDRA N. CHAKRAVARTI AND WM. H. PERKIN, JR. Dyson Perrins Lab., Oxford. *J. Chem. Soc.* 1929, 193-6.—5,2,3-(O₂N)₃MeO-C₆H₃CH:CHCO₂H (I), m. 231°, was prepd. by nitration of the 2,3-(MeO)₂ acid and also, which establishes its constitution, by condensation of 5,2,3-O₂N(MeO)₃C₆H₃CHO with CH₂(CO₂H)₂, using piperidine in C₆H₅N, the yield being nearly quant. Me ester, m. 154-5°; Et ester, dimorphous, m. 116°. Reduction of I with FeSO₄ and dil. NH₄OH gives 5-amino-2,3-dimethoxycinnamic acid, m. 233° (decompn.); diazotized and treated with KCN-CuCN there results the 5-CN deriv., m. 251°, which is oxidized by KMnO₄ in Na₂CO₃ soln. to 5-cyano-2,3-dimethoxybenzaldehyde, m. 135°; hydrolysis with concd. HCl on the steam bath for 3 hrs. gives isobipanic acid, m. 210-1° (first prepd. by Tiemann and Mendelsohn, *Ber.* 10, 397(1877)); the Me ester may be prepd. by hydrolysis in MeOH. C. J. WEST

Ozonization of nopinene and sabinene. HARRY SCHMIDT. *Z. angew. Chem.* 42, No. 5, 126-7(1929).—Nopinene, C₁₅H₂₄, from French turpentine oil, ozonized in alc.

and treated with steam, yielded, in the distillate, nopinone, $C_{10}H_{16}O$, b_{760} 209°, d_{20} 0.977, α_D 18.20°; semicarbazone, from MeOH, m. 188°; trichloride, from alc., m. 148°; benzal compd., from alc., m. 106°, slightly *l*-rotatory in alc. Another distillable product, $C_{10}H_{16}O_2$, a yellow, unpleasant smelling oil, also resulted from the O_3 treatment. It reacted slowly giving a disemicarbazone, $C_{10}H_{14}N_2O_2$, from alc., m. 210–2°, and probably is a stereoisomer of pinonic aldehyde. The α_D is -13.8° , whereas the known form gives 15° . Oxidation of this oil by 3% $KMnO_4$ gave a liquid, pinonic acid, d_{20} 1.095, giving, in MeOH, a semicarbazone, $C_{11}H_{15}O_2N_2$, m. 204–6°. The O_3 reaction also produced some neutral material and some pinonic acid, which were not volatile with steam. Sabinene, $C_{15}H_{24}$, treated as was the nopinene, gave colorless liquid sabinone, $C_{15}H_{22}O$, b. 217–9°, d_{20} 0.957, α_D -23° , stable to dil. $KMnO_4$. The semicarbazone, from dil. MeOH, m. 141°, gave the ketone with $(CO_2H)_2$.

G. ALBERT HILL

Structure of terpinol hydrate. A. S. GINZBERG AND M. S. ESHMAN. Leningrad Med. Inst. *J. Russ. Phys.-Chem. Soc., Chem. Pt.* 60, 1165–71 (1928).—The following expts. have led G. and E. to the conclusion that terpinol hydrate has a closed-chain formula and contains 1 mol. of crystn. H_2O : (1) Oxidation by $KMnO_4$ yields no product contg. an aldehyde or ketone group; (2) metallic Na, which does not act on terpinol at room temp., transforms terpinol hydrate into terpinol and 1 mol. H_2O ; (3) detn. of HO groups by means of Mg-org. compds. shows the presence of 2 HO groups and 1 mol. H_2O of crystn.; (4) $PhNCO$ acts on terpinol in anhyd. pyridine without formation of crystals or production of gas, whereas it produces both crystals and gas when reacting with terpinol hydrate, which circumstance indicates the presence of H_2O of crystn. in the latter; (5) benzoylation of terpinol hydrate in alk. soln. gives negative results, which would hardly be the case if the former contained a primary alc. group; (6) Nessler reagent, which is frequently utilized for detn. of primary alc. groups, does not react with terpinol hydrate. Terpinol hydrate is produced by the union with H_2O of *cis*- and not *trans*-terpinol.

BERNARD NELSON

Menthone series. VI. Crystallization of menthylamines with optically active acids. JOHN READ, CATHERINE CASSELS STEELE AND PETER GEORGE CARTER. Univ. of St. Andrews. *J. Chem. Soc.* 1929, 23–32; cf. *C. A.* 22, 86.—*dl*-Menthylamine and *dl*-neomenthylamine may be resolved by fractionally crystg. the H *d*-tartrates in the usual way; in each instance the salt contg. the desired form of the base was fortunately the less sol. of the 2 isomers; *dl*-isomenthylamine was not resolved when treated in a similar way. The tartrates and camphor-10-sulfonates gave essentially const. optical rotatory powers in dil. aq. solns. but with the α -bromocamphor- π -sulfonates considerable fluctuations were observed in the optical activity; with the latter only a partial resolution of the base could be achieved. Unexpectedly, however, the *d*-camphor-10-sulfonates prep'd. from the externally compensated bases exhibited very similar irregularities in their optical rotations and it was not found possible to resolve any of the cases with the help of this acid. *l*-Menthylamine *l*-camphor-10-sulfonate, $[M]_D$ -112° ; *d*-menthylamine *H d*-tartrate, m. 168°, $[M]_D$ 113°, $[M]_{589}$ 119°; *d*-neomenthylamine *l*- α -bromocamphor- π -sulfonate, m. 171°, $[M]_D$ -230° . The original should be consulted for the details of the variation of the optical activity on recrystn. and decompns. of these salts and others previously described.

C. J. WEST

Oxidation of dipinene. LINDSAY H. BRIGGS AND WALLACE F. SHORT. *J. Chem. Soc.* 1928, 3118–21; cf. Kondakov and Saprikin, *C. A.* 19, 3088; Carter, Smith and Read, *C. A.* 20, 1070.—To dipinene, from pinene with HCl and $FeCl_3$ in naphtha, in H_2SO_4 and H_2O was added com. MnO_2 . After refluxing 2.5 days more MnO_2 and H_2SO_4 were added. Soln. of oil was complete in 1 more day. Dila., filtration and extn. of the residue with dil. $NaOH$ followed. The alc.-free Et_2O ext. amounted to 6 g. from 22 g. dipinene. After soln. in NH_3 and filtration the Ag salts were obtained and methylated with MeI . The esters on fractionation and hydrolysis showed the presence of $BzOH$, terephthalic acid, and a $C_6H_5(CO_2H)_2$, probably mellitic. From one fraction no homogeneous substance was obtained. It is probable that diterpenes of this type contain 2 benzene rings united through 1 or 2 C atoms (cf. Ruzicka and Rudolph, *C. A.* 22, 1154).

FOSTER DEE SNELL

Ultra-violet absorption curves of the pulegonenols. JEAN SAVARD. *Bull. soc. chim.* 43, 978–84 (1928).—A further study (cf. *C. A.* 22, 157, 3583) was made of the absorption spectra of pulegone and isopulegone, together with their enols, and also of butylpulegol and isobutylpulegol. The presence of even a small amt. of pulegone in the enol form causes the appearance of a max. point due to CO ; the enolization of pulegone, contg. $C:C$, lowers the max. absorption. The substitution of the alc. group for the ketone lowers the max. absorption of the double bond.

E. G. VANDER BOSCH

***l*-Menthone.** L. T. SANBORN. *Org. Syntheses* 9, 52-3(1929).—Oxidation of 90 g. menthol by 120 g. $\text{Na}_2\text{Cr}_2\text{O}_7$ and 100 g. concd. H_2SO_4 in 600 cc. H_2O gives 83-5% of *l*-menthone, b_{11} 98-100°, b 204-7°.

Camphenilane series. II. Apocyclene, camphenilene and some of their derivatives. S. S. NAMETKIN AND ZINAIDA ALEKSANDROVA. Second Univ. Moskau. *J. Russ. Phys.-Chem. Soc., Chem. Part* 60, 1535-44; *Ann.* 467, 191-200(1928); cf. *C. A.* 18, 3371.—The structure of α -isocamphenilone (I) has now been detd. by prepg. it from apocyclene (II) and examn. of the products of fission of the cyclopropane ring in the latter by hydration has shown that fission probably takes place in all 3 possible ways, for fission of either the C^1-C^6 or C^3-C^4 linkings must yield the alcs. corresponding with camphenilone (III) and I, and fission of the C^1-C^3 linking the alc. corresponding with apocamphor; all these ketones were isolated. II was prepd. from the hydrazone of III by oxidation with HgO in EtOH . Treatment of II with AcOH and 50% H_2SO_4 yields a mixt. of alcs., m . 51-60°, b_{11} 100.5-1°. After oxidation of this mixt. with CrO_3 - AcOH , apocamphor was sepd. by crystn. of its semicarbazone and yielded apocamphoric acid on oxidation with alk. KMnO_4 . After oxidation of the mixt. with concd. HNO_3 and then with alk. KMnO_4 , III and I, m . 65-6°, were sepd. by crystn. of the semicarbazones. *cis*-Apofenchocamphoric acid, derived from I, was sepd. from the product of the KMnO_4 oxidation. I was sepd. in largest amt. and this reaction provides a convenient method of prepn. Reduction of the ketones with Na and EtOH yielded a mixt. of the stereoisomeric α -isocamphenilols, b 196-8°. When treated with K and CS_2 and then with MeI this yielded *Me* α -isocamphenilylvanilate, which decomps. when heated at 150-60° to yield camphenilene (V), b 131-2°, m 27-8°. Oxidation of V with alk. KMnO_4 gives IV.

Quinoxalines (prepared) from camphorquinone and aromatic α -diamines. A. HEGKENDORN. Univ. Lausanne. *Helv. Chim. Acta* 12, 50-60(1929).—Only the simple camphorquinoxaline has been prepd. by condensation of camphorquinone (I) with α - $\text{C}_6\text{H}_4(\text{NH}_2)_2$ (II) (Singh and Mazumdar, *C. A.* 14, 1812). This prepn. is repeated and extended to substituted α -diamines. The compds. must be considered as true quinoxalines, since the camphor group hardly shows any longer the aromatic character. They bear only remote resemblance to azines, showing only faintly the characteristic H_2SO_4 reaction of azines. In the case of monosubstituted C_6H_4 rings, 2 products are theoretically obtainable (III and IV). Only one, however, is obtained in all cases, and its constitution has, therefore, not been elucidated.

(III)

(IV)

(A) **Camphorquinoxaline.**—Mol. proportions of I and II.2HCl are mixed in EtOH and heated. The product is obtained as a viscous mass by diln. with H_2O . It turns to an amorphous solid by rubbing. After careful drying, it seps. from petroleum ether in monoclinic or trigonal crystals, often twinned, m . 74°. Acetylation, benzoylation and nitration yield only the original materials. (B) **2-Methylcamphorquinoxaline.**—As above, using 1,2,3- $\text{C}_6\text{H}_3\text{Cl}(\text{NH}_2, \text{HCl})_2$, H_2O ppts. the product as an oil, which is extd. with Et_2O . Shaking with concd. HCl gives the HCl salt, which after sepn. of Et_2O and hydrolysis with H_2O gives the final product, also obtained by crystg. the oil by cooling with ice and salt in needles, insol. in H_2O , sol. in EtOH , Et_2O , C_6H_6 , petroleum ether and concd. acids, m . 50°. Yield, 60%. (C) **2-Chlorocamphorquinoxaline.**—As — (B) using 1,3,4- $\text{C}_6\text{H}_3\text{Cl}(\text{NH}_2)_2$. Yield, 55-60%. Dissolved in 1:1 petroleum ether- C_6H_6 , filtered, concd. and crystd. by rubbing, it softens, then m . 98°, sol. in EtOH , Et_2O , C_6H_6 , petroleum ether and concd. acids, in H_2SO_4 with yellow color.

The dehydration also takes place by heating in EtOH, or by allowing the ppt. to stand overnight in the mother liquor. The diquinoxaline, recrystd. from C_6H_6 , after decolorizing with charcoal, m. 333-5°, is sol. in concd. acids (the H_2SO_4 soln. is yellow), pptd. by H_2O , sol. in EtOH and C_6H_6 , slightly in Et_2O and petroleum ether. (b) 2,3-Diaminocamphorquinoxaline.—The condensation takes place in EtOH, with enough H_2O added to dissolve the HCl salt, and a small amount of dil. HCl. After short warming, the soln. turns dark red. No pptn. takes place on dilg. with H_2O . The EtOH is evapd. on a steam bath, and NH_3 is added. The mass is extd. several times with Et_2O , and the soln. is concd. This is then reextd. with fairly concd. H_2SO_4 . The soln. has the color of $KMnO_4$ (dibasic salt), and turns orange-red on diln. (monobasic salt). With an excess of concd. H_2SO_4 or with fuming acid, the soln. turns colorless, corresponding to the tri- or tetrabasic salt. The H_2SO_4 soln. of the dibasic salt is treated slowly with NH_3 , and the orange monobasic salt is pptd. This, treated with NH_3 , gives the free base as a yellow powder, sol. in Et_2O , EtOH, C_6H_6 , slightly sol. in H_2O , insol. in petroleum ether, all solns. being highly fluorescent, with the same cast as (F) above, while the unsym. isomer (G) above is not fluorescent. Purified by dissolving in C_6H_6 and pptg. by petroleum ether, it softens 130-40°, and m. 165°. Picrate, orange powder, m. 176°, preceded by softening. (K) 1,2-Benzocamphorquinoxaline.—A suspension of α - $C_{10}H_7(NH_2)_2$ in EtOH is added to I in EtOH. A few drops of HCl are added to clarify the soln., which is heated for 30 min. If a ppt. forms on cooling, the condensation is incomplete. The soln. is dild. with H_2O and extd. with Et_2O . This is treated as in (E) above, with HCl, H_2O , then NH_3 . If instead the HCl soln. is treated with only a small amount of H_2O and the sides are rubbed with a glass rod, a yellow ppt. of the HCl salt is formed, which turns colorless upon diln. or addn. of NH_3 (free base). Recrystd. it m. 85-6°, forms a blue soln. in concd., canary-yellow in dil. H_2SO_4 . (L) 2,3-Diaminoanthraquinone camphorquinoxaline.—By refluxing for 2 hrs. 1 mol. of I with 1 mol. of 2,3-diaminoanthraquinone in glacial AcOH, using 250 cc. of solvent per g. of I. The soln. is filtered, and, after cooling, dild. with H_2O . Yield, 75%. The product is dried, dissolved in hot C_6H_6 , the soln. filtered and a small amount of impurities pptd. by addn. of an equal vol. of petroleum ether. The filtrate is concd. and the product seps. on cooling in orange-yellow needles, m. 211°, sol. in EtOH, Et_2O , C_6H_6 , petroleum ether, glacial AcOH, Me_2O and concd. HCl. G. CALINGAERT

Molecular compounds of aromatic iodides. PAUL PFRIFER, HELMUT SCHMITZ AND TOSHI INOUE. Univ. Bonn. *J. prakt. Chem.* 121, 70-84(1929).— $PhCH_2I$ in $CHCl_3$ and Cl_2 give a dichloride, yellow, m. 102° (decompn.) (72% yield); the corresponding iodoso deriv., pale yellow, m. 225-30°, could not be obtained pure. $MeIC_6H_4I$, yellow, m. 109-10° (Stollé, *Ber.* 21, 1099(1888) gives 99-100°), the Cl deriv. m. 58-8.5° (S. gives 51°); the Br deriv. m. 71° (S. gives 58-9°); the iodide dichloride, yellow, m. 101-2° (decompn.). 3,3'-Dimethoxy-4,4'-diiodobiphenyl, orange yellow, m. 181.5-3°, results in 67% yield from *o*-dianisidine; the dichloride, greenish yellow, m. 109-10° (decompn.). 3,3'-Dinitro-4,4'-diiodobiphenyl, greenish yellow, m. 246-7°. 4-Iodostilbene, m. 152°; the 2- NO_2 deriv., greenish yellow, m. 110 (14% yield); 2-nitro-4-iodo-4'-methoxystilbene, golden yellow, m. 100-100.5° (18% yield). F.-p. data and curves are given for the systems p - IC_6H_4Ph and piperonalacetophenone (which do not form a compd.), dianisalacetone (which form a mol. compd. in the ratio of 1:2), dipiperonalacetone, sarcosine anhydride, α - $C_{10}H_7OH$, menthol, α - $C_{10}H_7NH_2$ and 1,3,5- $C_6H_3(NO_2)_3$ (none of which forms a mol. compd. with IC_6H_4Ph) and for Ph and dianisalacetone, which, likewise, do not form a mol. compd. C. J. WEST

Utilization of titanium tetrachloride in organic syntheses. G. L. STADNIKOV AND L. I. KASHTANOV. Moscow Coal Research Lab. *J. Russ. Phys.-Chem. Soc., Chem. Pt.* 60, 1117-22(1928).— $TiCl_4$ being analogous to $SnCl_4$, an investigation was made whether it has a similar behavior in org. reactions. Benzene does not react with $TiCl_4$. Benzyl Et ether in presence of $TiCl_4$ in C_6H_6 decomps., forming at first $PhCH_2Cl$, after which the latter reacts with C_6H_6 and gives mono- and disubstituted derivs. 50 g. $TiCl_4$ is dropped with agitation and cooling into a soln. of 72 g. benzyl ethyl ether in 350 g. of dry C_6H_6 , whereupon the soln. gradually darkens. After being boiled 10 hrs. on a water bath to drive off HCl fumes, the mixt. is decompd. with water and fractionated at 10 mm. 46.5 g. Ph_2CH_2 , and 17.8 g. of a mixt. of *p*- and *m*- $C_6H_4(CH_2Ph)_2$ have thus been obtained. Benzyl chloride.—20 g. $PhCH_2Cl$ was added drop by drop to 20 g. $TiCl_4$ in 200 g. dry C_6H_6 , the mixt. was boiled on a water bath till the cessation of HCl fumes and, after decompn. by H_2O , was fractionated, yielding 9.4 g. CH_2Ph_2 , 1.6 g. *p*- $C_6H_4(CH_2Ph)_2$, 1.8 g. *m*- $C_6H_4(CH_2Ph)_2$ and 6.6 g. residue. Benzoyl chloride and benzene in presence of $TiCl_4$ do not yield $PhCOMe$; $BzOH$ is obtained quant. The introduction of the Bz radical into the thiophene ring takes place easily: 22.2 g. $BzCl$

was added drop by drop to 13.3 g. thiophene and 30 g. TiCl_4 in 250 g. C_6H_6 , the mixt. was boiled on a water bath 5 hrs., then decompd. by water and, on being fractionated, yielded 27.8 g. crude benzothienone. If the expt. is made by dropping TiCl_4 into thiophene and BzCl in C_6H_6 , the yield of the ketone is 98%. This reaction may be utilized for the quant. detn. of thiophene in crude C_6H_6 . *Iso- and diso-Am esters of acetic and benzoic acids do not decomp. in presence of TiCl_4 in C_6H_6 .*

BERNARD NELSON

Dehydration of benzohydrol by the xanthate method. D. N. KURSANOV. *J. Russ. Phys.-Chem. Soc., Chem. Part* 60, No. 6, 921-4 (1928).—Among the products obtained by Nef (cf. *Ann.* 298, 235 (1897)), by heating Ph_2CHOH was supposed to be $(\text{Ph}_2\text{C})_2$, but it was not actually detected. By effecting the complete dehydration of Ph_2CHOH by the xanthate method of Chugaev, K. actually obtained $(\text{Ph}_2\text{C})_2$ as decompn. product. Twenty g. Ph_2CHOH , 4.7 g. metallic K and 90 cc. dry C_6H_6 were heated on a water bath 25 hrs. After removing the unchanged K (0.15 g.), 10 g. CS_2 was added which pptd. K benzohydrylxanthate, $\text{Ph}_2\text{CHOC}_2\text{S}_2\text{K}$. The pptn. having been completed on a water bath, the salt was esterified by boiling with 20 g. MeI for 3 hrs.; 27 g. of the ester $\text{Ph}_2\text{CHOC}_2\text{S}_2\text{Me}$ were obtained as a thick uncongealing yellow liquid. On heating the ester in a Würtz flask, the decompn. began at 190° and was completed at 260° . A few g. of crystals of $(\text{Ph}_2\text{C})_2$ were formed on the bottom of the flask; after recrystn. from a mixt. of alc. and C_6H_6 they m. $223-4^\circ$. $\text{Ph}_2\text{CHOC}_2\text{S}_2\text{Me} = \text{COS} + \text{MeSH} + \text{Ph}_2\text{C} < ; 2\text{Ph}_2\text{C} < = \text{Ph}_2\text{C}:\text{CPh}_2$.

BERNARD NELSON

Use of magnesium and methanol as a reducing agent. L. ZECHMEISTER AND P. ROM. *Univ. Pécs. Ann.* 468, 117-32 (1929).— Ph_2CO (9.1 g.) in 200 cc. abs. MeOH is reduced by 4.55 g. Mg during 2 hrs., giving 98% of Ph_2CHOH , m. 64° or 89%, m. 67.5° ; approx. the same yield can be obtained in a shorter time by the use of Mg and NH_4Cl in com. EtOH. $(\text{PhCH}_2)_2\text{CO}$ gives 89% of $(\text{PhCH}_2)_2\text{CHOH}$; BzMe gives 45.5% of PhMeCHOH , b_{780} 204° , and 11% of the pinacol, m. 124° . BzCH_2Br (7.96 g.) and 11.67 g. Mg in 300 cc. MeOH give 68% of PhMeCHOH ; the splitting off of the Br is quant. $p\text{-MeOC}_6\text{H}_4\text{Ac}$ gives 47% of $p\text{-MeOC}_6\text{H}_4\text{CH}(\text{OH})\text{Me}$, b_{780} 310° ; the distn. residue contains a little pinacol. $\text{PhCH}:\text{CHAc}$ gives 77% of $\text{PhCH}_2\text{CH}_2\text{CH}(\text{OH})\text{Me}$, b_{780} 238° , b_{11} $123-4^\circ$; $\text{CO}(\text{CH}:\text{CHPh})_2$ gives 70% of $\text{CH}(\text{OH})(\text{CH}_2\text{CH}_2\text{Ph})_2$, m. $42-4^\circ$. Ph_2CCl_2 , Mg and MeOH give 85.5% of $\text{Ph}_2\text{C}(\text{OMe})_2$. PhCl is not reduced; PhBr gives about 60% C_6H_6 , while PhI , $\alpha\text{-C}_{10}\text{H}_7\text{Br}$ and $\alpha\text{-C}_{10}\text{H}_7\text{Cl}$ are quant. reduced to C_6H_6 or C_{10}H_8 . PhNO_2 (6.15 g.), 110 cc. MeOH and 6 g. Mg give 27.5% $(\text{PhNH})_2$; if the crude product is not recrystd. but distd. with Fe or Mg powder, the yield is 70%. When 24.6 g. PhNO_2 , 600 cc. MeOH and 10.95 g. Mg are heated, there results 24.5% of azoxybenzene. $o\text{-O}_2\text{NC}_6\text{H}_4\text{Me}$ gives 57% of 2,2'-dimethylazoxybenzene; $m\text{-O}_2\text{NC}_6\text{H}_4\text{Me}$ gives 69% of the 3,3'- Me_2 deriv., while $p\text{-O}_2\text{NC}_6\text{H}_4\text{Me}$ gives 61% of the 4,4'- Me_2 deriv. $o\text{-ClC}_6\text{H}_4\text{NO}_2$ gives 60% of 2,2'-dichloroazoxybenzene (Mg and NH_4Cl give 57%; corresponding figures will be given for the other compds.); $m\text{-ClC}_6\text{H}_4\text{NO}_2$ gives 80% of the 3,3'- Cl_2 derivs. (90%); $p\text{-ClC}_6\text{H}_4\text{NO}_2$ gives 81% of the 4,4'- Cl_2 deriv. (81%); $o\text{-BrC}_6\text{H}_4\text{NO}_2$ gives 32% of the 2,2'- Br_2 deriv. (30%); $m\text{-BrC}_6\text{H}_4\text{NO}_2$ gives 70% of the 3,3'- Br_2 deriv. (59%); $p\text{-BrC}_6\text{H}_4\text{NO}_2$ gives 84% of the 4,4'- Br_2 deriv. (57%); 2,5- $\text{Br}_2\text{C}_6\text{H}_3\text{NO}_2$ gives 80% of 2,2',5,5'-tetrabromoazoxybenzene, light yellow, m. 166° (cor.), which gives an intense carmine-red color with concd. H_2SO_4 . C. J. W.

New substantive dyes derived from 2,7-diaminofluorene. A. NOVELLI AND C. CELSTINO RUIZ. *Anales asocn. quim. Argentina* 16, 56-64 (1928).—2,7-Diaminofluorene tetrazoate has been prepd. and coupled with two naphthylaminosulfonic acids. The respective bisazo compds. have thus been obtained. They are analogous in all properties to those obtained from benzidine. This is another evidence in favor of the similarity of fluorene and benzidine. The directions of Butler and Adams (C. A. 19, 3267), have been modified.

ALBERT L. HENNE

Ammonium salt of aurintricarboxylic acid. G. B. HEISIG AND W. M. LAUER. *Org. Syntheses* 9, 8-10 (1929).— $o\text{-HOC}_6\text{H}_4\text{CO}_2\text{H}$ (20 g.) is dissolved, at 20° , in a soln. of 10 g. NaNO_2 in 70 cc. concd. H_2SO_4 , the soln. cooled to 0° and treated with 5 cc. of 35-40% HCHO and the resulting acid dissolved in dil. NH_4OH ; evapn. of the soln. gives 83-96% of the light yellowish brown NH_4 salt, sufficiently pure for use as a test for Al.

C. J. WHEAT

Preservation of optical activity in splitting out water from optically active glycols. II. Formation of optically active ketones by the semi-pinacolin rearrangement. ROBERT ROGER AND ALAN MCKENZIE. St. Andrew's Univ. *Ber.* 62B, 372-84 (1929).—A soln. of *l*-Et mandelate treated with the Grignard reagent from PhCH_2Cl , decompd. by H_2O gave the *d*-glycol (*d*-2-phenyl-2-hydroxy-1,1-dibenzylethanol). On dehydration with cold concd. H_2SO_4 , racemization occurs (cf. C. A. 19, 491), but by boiling with 57% H_2SO_4 is obtained the optically active ketone *d*- α - γ -diphenyl- γ -benzyl-

acetone which is racemized by traces of alc. KOH or by soln. in cold. coned. H_2SO_4 . *l*-Benzoin treated with the Grignard reagent from PhCH_2Cl and decompd. by H_2O gives *l*-1,2-diphenyl-2-hydroxy-1-benzylethanol, which on dehydration with AcCl gives an inactive benzylhydrobenzoin. R. and McK. discuss the mechanism of the conversion of the glycol to the ketone with and without racemization on the basis of an intermediate ethylene oxide compd. or of a vinyl deriv. A. P. SACHS

Dihydro- and tetrahydronaphthoic acids obtained by catalytic hydrogenation. A. LEÓN AND A. CHARRO. *Anales soc. españ. fís. quim.* 26, 423-9 (1928); cf. C. A. 22, 777.—Catalytic hydrogenation by Pt oxide in the cold of naphthoic acids gave two isomers of dihydro- β -naphthoic acid, m. 132° and $140-1^\circ$, resp., not coinciding with any given in the literature. The corresponding amides, m. $133-4^\circ$ and 191° , resp. Tetrahydrogenation gave only one compd., m. 153° ; amide, m. 139° . Perhydrogenation of this acid gave the same decahydro acid as already obtained by direct perhydrogenation of $\beta\text{-C}_{10}\text{H}_7\text{CO}_2\text{H}$ (*loc. cit.*). E. M. SYMMES

ac-Tetrahydro- β -naphthylamine. E. B. H. WASER AND H. MÖLLERING. *Org. Syntheses* 9, 84-9 (1929).—Complete details are given for the reduction of $\beta\text{-C}_{10}\text{H}_7\text{NH}_2$ with Na and AmOH , the yield of the tetrahydro deriv. being 51-7%. The base b_1 118.5° , b_{11} $127.5-8^\circ$, b_{10} $140-40.5^\circ$. C. J. WEST

β -Naphtholphenylaminomethane. M. BETTI. *Org. Syntheses* 9, 60-3 (1929).—By allowing a mixt. of 144 g. $\beta\text{-C}_{10}\text{H}_7\text{OH}$ in 200 g. 95% EtOH, 212 g. BzH and 200 cc. 95% EtOH satd. with NH_3 at room temp. to stand 2 hrs. in a closed flask, then removing the stopper and, after 12 hrs., filtering, there results 85-92% of the condensation product $\text{PhCH}(\text{C}_{10}\text{H}_7\text{OH})\text{N}:\text{CHPh}$, m. $148-50^\circ$. This is treated with 3-4 times its vol. of 20% HCl and distd. with steam, giving 84-91% of the HCl salt of $\text{PhCH}(\text{C}_{10}\text{H}_7\text{OH})\text{NH}_2$, which is liberated with KOH; the yield of amine is 73-5%. C. J. W.

Synthesis of isonaphthothioxin. AARON COHEN AND SAMUEL SMILES. King's College, London. *J. Chem. Soc.* 1929, 209-13.—The diazo compd. from 1,2- $\text{C}_{10}\text{H}_6(\text{NH}_2)_2\text{SO}_2\text{H}$ and CuBr in HBr give 50% of the Br acid; PCl_5 gives 1-bromonaphthalene-2-sulfonyl chloride, m. $93-4^\circ$; reduction gives 60% of 1-bromonaphthalene-2-sulfinic acid (I), m. 146° (chloride, yellow, m. 110°). I is also obtained from 1,2- $\text{C}_{10}\text{H}_6(\text{BrNH}_2)_2$ through the diazo compd., SO_2 and Cu in 60% yield. I, reduced by SO_2 in EtOH contg. a little HI, gives 90% of di-1-bromonaphthyl 2-disulfide, m. 161° ; this also results nearly quant. by adding Br in AcOH to 2-naphthyl disulfoxide in AcOH, owing to reduction by the HBr liberated. Adding the theoretical amt. of Br in AcOH to 2-hydroxydinaphthyl 2,1'-disulfide in hot AcOH gives 95% of 1-bromo-2'-hydroxydinaphthyl 2,1'-sulfide (II), m. 154° (sometimes the product m. $135-6^\circ$, then resolidified and m. 154°). The structure of II was confirmed by heating I and $\beta\text{-C}_{10}\text{H}_7\text{OH}$ at $95-100^\circ$ for 2.5 hrs. Ac deriv. of II, m. $116-7^\circ$. The dry Na deriv. of II and a little $\text{Cu}(\text{OAc})_2$, heated at 1 mm., give 50% of isonaphthothioxin. C. J. WEST

Synthesis of meso-alkyl- and meso-arylanthracene derivatives. V. EDWARD DE B. BARNETT AND NORMAN F. GOODWAY. Sir John Cass Tech. Inst., London. *J. Chem. Soc.* 1929, 20-3; cf. C. A. 27, 3654.—1,5-Dichloro-9-benzohydrylanthracene (I), m. 191° , results in 50% yield from 1,5-dichloroanthracene, 20% KOH and PhCHCl by boiling 30 mins.; reduction gives 1,5-dichloroanthracene. I reacts with RMgX to give derivs. of benzohydryldichlorodihydroanthracene (the yield is only about 5% except in the case of the Me, Ph and PhCH_2 derivs.): Me, m. 160° ; Et, m. 140° ; $\alpha\text{-Pr}$, m. 185° ; $\beta\text{-Pr}$, m. 170° ; Bu, m. 182° ; iso-Bu, m. 212° ; iso-Am, m. 193° ; benzyl, m. 206° . Ph (II), m. 259° . I does not react with the *p*-anisyl, *o*-tolyl or α -naphthyl reagents. The Me, Et, benzyl and Ph compds., heated with AcOH contg. a little HCl, pass very easily into the corresponding alkyl- or arylanthracene. II, recrystd. from $\text{C}_6\text{H}_5\text{Me}$, shows a progressive rise in m. p. and when boiled 4 hrs., there results iso-1,5-dichloro-9-phenyl-10-benzohydryl-9,10-dihydroanthracene, m. 271° , which, with AcOH-HCl, gives 1,5-dichloro-9-phenylanthracene. C. J. WEST

Reduction products of the hydroxyanthraquinones. X. RICHARD W. HARDACRE AND ARTHUR G. PERKIN. Univ. of Leeds. *J. Chem. Soc.* 1929, 180-93; cf. C. A. 21, 2804.—Heating 1 g. 2,2'-diacetoxyhelianthron (I) and 3 g. I in 15 cc. $\text{C}_6\text{H}_5\text{N}$ gives 1.288 g. of 3,3'-diiodo-2,2'-dihydroxyhelianthron, maroon, whose di-Ac deriv., orange, m. $268-70^\circ$ (decompn.). I and Br in cold $\text{C}_6\text{H}_5\text{N}$ give the corresponding 3,3-di-Br deriv., brick-red; di-Ac deriv., orange-red, m. $293-6^\circ$. The 3-I deriv. of I (1 g.) in 1800 cc. C_6H_6 , exposed to light for 3 weeks, gives the pale yellow 3-iodo-2,2'-diacetoxy-naphthodianthrone, m. above 340° , which gives a red soln. in H_2SO_4 and evolves I when strongly heated. 2-Hydroxyanthraquinone in boiling 1% NaOH, gradually treated with NaOBr and boiled for 1 hr., gives the 1,3-di-Br deriv. (II), yellow, m. $216-7^\circ$; *o*-Ac deriv., yellow, m. 195° ; 2-MeO deriv., pale yellow, m. $226-7^\circ$. II heated with

concd. NaOH at 200° for 6 hrs. gives 3-bromoalizarin, whose di-Ac deriv., m. 201–2°. 1-Bromo-2-hydroxyanthraquinone, yellow, m. 185–7°; Ac deriv., yellow, m. 182–3°; MeO deriv., m. 247°; Bz deriv., yellow, m. 229–30°. The Br deriv., boiled in C₁₀H₈ with Cu, gives 2,2'-dihydroxy-1,1'-dianthraquinonyl (III). 1-Chloro-2-methoxyanthraquinone, yellow, m. 223–4°, does not react with Cu in boiling PhNO₂; the 2-Bz deriv., yellow, m. 228–30°, with Cu in C₁₀H₈, gives III. III, reduced with Zn and dil. NH₄OH, gives, after acetylation, a mixt. of 3,9-diacetoxyanthracene, m. 157–8°, and the tetra-Ac deriv., yellow, m. 267–8°, of 2,2'-dihydroxy-1,1'-dianthranolyl, yellow, m. about 290°. If the Zn is added all at once, only the latter product is formed. 1-Chloro-2-hydroxyanthraquinone, reduced with Al in H₂SO₄ at 30–40°, gives chlorohydroxyanthranol, greenish yellow, m. 230°, isolated through the di-Ac deriv., light yellow, m. 168°. 2-Hydroxyanthraquinone and I in C₆H₅N, boiled 15 mins., give the 3-I deriv. (IV), yellow, m. 278–9°, isolated through the Ac deriv. (V), yellow, m. 224–5°; 2-MeO deriv., pale yellow, m. 228–9°; treatment of the latter with MeONa at 110° for 12 hrs. removes the I, while concd. NH₄OH and a trace of Cu at 160–80° for 8 hrs. give 3-amino-2-hydroxyanthraquinone, reddish brown with metallic iridescence; the NH₂ group could not be replaced by OH. IV and BzCl in C₆H₅N give the 2-Bz deriv., yellow, m. 185°, which, heated with Cu in C₁₀H₈ and the product acetylated, gives 3,3'-diacetoxo-2,2'-dianthraquinonyl, m. 315°. Reduction of V with Al in H₂SO₄ gives 2-iodo-3-hydroxyanthranol, m. 239–40°, isolated through the di-Ac deriv., m. 196°. The latter, with FeCl₃ in AcOH, heated at 100° for 45 mins., gives 2,2'-diiodo-3,3'-dihydroxydianthrone (VI), yellow, m. 267–8°; H₂SO₄ and Ac₂O give a di-Ac deriv., m. 227–8°; boiling Ac₂O and C₆H₅N give the tetra-Ac deriv. of 2,2'-diiodo-3,3'-dihydroxydianthrone, yellow, crystg. with 2 mols. Me₂CO, m. 220°, then resolidifies and m. 290°; from Ac₂O, it m. 293–5°. VI and K₂Fe(CN)₆ in 10% NaOH give 2,2'-diiodo-3,3'-dihydroxydianthraquinone, whose di-Ac deriv., m. 306–8°. With K₂S₂O₈, VI gives 3,3'-diiodo-2,2'-dihydroxyheli-anthrone. Acetylanthrapurpurinanthranol and FeCl₃ in AcOH give a mixt. of a yellow and a blue amorphous compd., the former of which, with Ac₂O gives 3,4,6,3',4',6'-hexaacetoxydianthrone, m. 250–1°. The latter, exposed in AcOH to the sunlight, yields 3,4,6,9,3',4',6',9'-octaacetoxydianthrone, m. 239–40°.

C. J. WEST

Derivatives of aminomethylhydroxyanthraquinones and dihydroxydianthraquinonyl-ethylenes. HENRI DE DIESBACH AND PAUL GUBSER. *Helv. Chim. Acta* 11, 1098–1125 (1928).—D. and G. have studied the reaction of 3 methylols—PhCONHCH₂OH (I), Cl₃CCONHCH₂OH (II), C₆H₄(CO)₂NCH₂OH (III)—in concd. H₂SO₄ with 1-(IV) and 2-hydroxyanthraquinone (V), 1-(VI) and 3-hydroxy-2-methylanthraquinone (VII), 2-hydroxyanthraquinone-3-carboxylic acid (VIII), 2,3-(hystazarin) (IX), 1,5-(anthra-rufin) (X) and 1,8-dihydroxyanthraquinone (chrysazin) (XI), the following compds. being prepd.: 1-trichloroacetylaminomethyl-2-hydroxyanthraquinone (XII) from II and V, m. 215°, 1-benzoylaminomethyl-2-hydroxyanthraquinone from I and V, m. 250° (decompn.), N-[2-hydroxy-1-anthraquinonylmethyl]phthalimide, m. 265° (decompn.) and N-[2-hydroxy-1-anthraquinonylmethyl]phthalimidic acid (XIII) from III and V, 4-trichloroacetylaminomethyl-1-hydroxyanthraquinone, yellow, m. 197°, from II and IV, 4-benzoylaminomethyl-1-hydroxyanthraquinone, m. 208° and 2,4-bis[benzoylaminomethyl]-1-hydroxyanthraquinone, m. 276°, formed simultaneously from I and IV, 2,4-bis[phthaloylaminomethyl]-1-hydroxyanthraquinone, m. 295°, and bis-N-[1-hydroxyanthraquinonyl-2,4-methyl]phthalamidic acid, m. 178°, formed simultaneously from III and IV, 4-trichloroacetylaminomethyl-1-hydroxy-2-methylanthraquinone (XIV), m. 239°, from II and VI, 4-phthaloylaminomethyl-1-hydroxy-2-methylanthraquinone (XV), m. 285°, from III and VI, 1-trichloroacetylaminomethyl-2-hydroxy-3-methylanthraquinone, m. 227°, from II and VII, 1-phthaloylaminomethyl-2-hydroxy-3-methylanthraquinone, m. 244°, from III and VII, 1-trichloroacetylaminomethyl-2-hydroxyanthraquinone-3-carboxylic acid (XVI), decomp. without melting at 260°, from II and VIII, 1-phthaloylaminomethyl-2-hydroxyanthraquinone-3-carboxylic acid, m. 290°, from III and VIII, 1,4-bis[trichloroacetylaminomethyl]-2,3-dihydroxyanthraquinone (XVII), m. 253°, from II and IX, 1,4-bis[phthaloylaminomethyl]-2,3-dihydroxyanthraquinone, m. 272°, from III and IX, 4(?)-phthaloylaminomethyl-1,5-dihydroxyanthraquinone, decomp. 230°, from III and X, 2,4,6,8-tetra[trichloroacetylaminomethyl]-1,5-dihydroxyanthraquinone, decomp. 275°, from II and X, 2,4,5-tri[benzoylaminomethyl]-1,8-dihydroxyanthraquinone, decomp. 250° without melting, prepd. from I and XI, 2,4,5,7-tetra[phthaloylaminomethyl]-1,8-dihydroxyanthraquinone, from III and XI, 2,4,5,7-tetra[trichloroacetylaminomethyl]-1,8-dihydroxyanthraquinone, decomp. 260°, from II and XI. 2-Hydroxy-1,9-(N)isopyrrolanthrone (XVIII) is prepd. by treating XII with boiling 10% NaOH in H₂O 4 hrs. XVIII and BzCl in pyridine give 2-benzoyloxy-1,9-(N)isopyrrolanthrone. The treatment of XVIII with boiling AcOH gives sym. 1,1'-(2,3'-dihydroxydianthra-

quinonyl]glycol (XIX). XIX and BzCl in pyridine give 1,1'-[2,2'-dibenzoyldioxydianthraquinonyl]-dibenzoylglycol, which is very hygroscopic. sym.-1,1'-[2,2'-Dihydroxydianthraquinonyl]ethylene (XX) is prepd. by treating XII with boiling 10% NaOH in O (66%) as bronze crystals. Di-Bz deriv. prepd. from XX, BzCl and pyridine, 2-Hydroxyanthraquinone-1-carboxylic acid, formed as a secondary product in the prepn. of XX, m. 237°. Sapon. of XIII with 10% NaOH gives 1-aminomethyl-2-hydroxyanthraquinone (XXI). XXI, phthalic acid and AcOH in sealed tube at 170° for 4 hrs give sym.-1,1'-[2,2'-dihydroxydianthraquinonyl]ethylenediamine, which on heating in PhNO₂ gives XX. XIV with boiling 10% NaOH in H gives 1-hydroxy-2-methyl-4,10-(N)-isopyrrolanthrone, and in O gives sym-4,4'-[1,1'-dihydroxy-2,2'-dimethyldianthraquinonyl]ethylene. Sapon. of XV with NaOH gives 1-hydroxy-2-methyl-4-aminomethylanthraquinone (XXII) as an addn. product with phthalic acid, which when heated to 170° with AcOH in a sealed tube gives sym-4,4'-[1,1'-dihydroxy-2,2'-methyldianthraquinonyl]ethylenediamine. Sapon. of XVI in H gives 1-aminomethyl-2-hydroxyanthraquinone-3-carboxylic acid which is very unstable, forming sym-1,1'-[2,2'-dihydroxy-3,3'-dicarboxydianthraquinonyl]glycol. XVI with 10% NaOH at 70° gives sym-1,1'-[2,2'-dihydroxy-3,3'-dicarboxydianthraquinonyl]ethylene along with which is formed 2-hydroxyanthraquinone-1,3-dicarboxylic acid. XVII and 10% NaOH, 2-3 mins at 60°, followed by treatment with HCl gives the HCl salt of 1,1'-[2,2',3,3'-tetrahydroxy-4,4'-bis(aminomethyl)dianthraquinonyl]- α -hydroxy- β -aminoethane. F. C. H.

2-Aminoanthraquinone from chlorobenzene and phthalic anhydride. P. H. GROGGINS and H. P. NEWTON. *Ind. Eng. Chem.* 21, 369-75(1929).—Chlorobenzene, phthalic acid (I) is obtained in a com. pure state (96.7%) with almost theoretical yield when 3 mols. PhCl, 1 mol. C₆H₄(CO)₂O and 10% excess AlCl₃ are heated 5 hrs at 50° with thorough agitation, decompd. slowly with dil. H₂SO₄, steam distd. to remove PhCl, washed with H₂O, dissolved in 2.5% NaOH, blown with steam to remove traces of PhCl, cooled to 50° and added slowly to a large vol. of dil. H₂SO₄. When I is heated with H₂SO₄ (cf. C. A. 19, 2335), 2-chloroanthraquinone (II), m. 211°, is obtained—the yields (98-9%) and purity, which are dependent on conditions, were studied and are tabulated. Heating II with 28.5% aq. NH₃ at 215° from 6 to 18 hrs. gave 88% of 2-aminoanthraquinone (III), which may have as impurities II (from incomplete conversion), carbonaceous material (from excessive heating), dianthraquinonylamine (from a condensation reaction), traces of Fe (from the reaction vessel) and hydroxyanthraquinone (characteristic side reaction). The last mentioned impurity can be reduced by adding a small quantity of PhNO₂ to the 28.5% NH₃ or by using 40-50% NH₃. Purification of III by heating with 6-10 parts H₂SO₄ for 30 mins at 125°, dilg with H₂O, cooling, filtering, washing with hot H₂O and then boiling with a slight excess dil. Na₂CO₃ was found to be an economical method of producing a relatively pure (95-98%) product which is suitable for the prepn. of vat dyes. N. A. LANGRISH

Inductive method for the study of natural products. I. Naturally occurring anthraquinone derivatives. P. C. MITTER AND HAROGOPAL BISWAS. Univ. College of Science, Calcutta. *J. Indian Chem. Soc.* 5, 769-78(1928).—An examn. of naturally occurring C₁₄H₈O₂ derivs. shows that (1) none of them contains more than 1 Me (or CO₂H or carbinol) group or more than 3 OH groups, (2) the substances cont. the max. no. of substituents form the 4 fundamental types, (3) of the 4 substituents 2 (including Me or CO₂H or carbinol if present) occupy β -positions and 2 occupy α -positions, (4) if both the β -substituents are in one ring, the other groups are in the same ring, forming the 2 homonuclear types, (5) if the β -substituents are in different rings, the α -substituents are distributed so as to produce a sym. configuration, forming the 2 heteronuclear types. The homonuclear types are the chayroot (root of *Oldenlandia umbellata* (Linn)) and madder types; the heteronuclear are the emodin and morindone types. The following anthraquinones were prepd.: 1,5-dimethoxy-6-methyl, m. 170-7°; 1,5-dihydroxy-6-methyl, yellow, m. 190° (cf. Perkin and Hummel, *J. Chem. Soc.* 65, 857(1894), and Oesterle and Tisza, C. A. 2, 1997) and its Ac deriv., m. 230°. Condensation of hemipink anhydride with PhMe in presence of AlCl₃ gave 3-hydroxy-4-methoxy-2-*p*-toluoylbenzoic acid, m. 175-6°. This heated on the water bath with H₂BO₃, concd. H₂SO₄, and fuming H₂SO₄ gave 1-hydroxy-3-methoxy-6-methylanthraquinone (I), orange-yellow, m. 200°. *Ac deriv.*, m. 170°. Demethylated, I gave 6-methylanthraquinone, yellow, m. 220°. *Ac deriv.*, m. 190°. LOUISE KELLY

Pyrogenous dissociation of certain condensed cyclic compounds. N. A. OZLOV. Leningrad Acad. of Science. *J. Russ. Phys.-Chem. Soc.*, *Chem. Part* 60, No. 8, 1447-58(1928).—Having previously established (C. A. 22, 75) by using phenanthrene as an example, that condensed ring systems, when heated with compressed H₂, become hydrogenated before dissociating, O. now proceeds to a more detailed study of

the hydrogenation products of phenanthrene and of some related coal-tar hydrocarbons. The pyrolysis expts. were made in an 800-cc. Ipat'ev app., the initial H pressure was 70–75 atm., the max. 170 atm. at the temp. of 450–70°, the duration of heating being 7–9 hrs., after which the products obtained were fractionated and examd. Similar products were obtained by mere distn. with anhyd. AlCl_3 in a Würtz flask. The following hydrocarbons have thus been hydrogenated and dissociated: tetrahydropheanthrene (tetanthrene), methylisopropylphenanthrene (retene), fluorene, anthracene, tar oil. The conclusions are: Hydrocarbons with condensed rings suffer but partial hydrogenation, apparently chiefly to the stage of tetrahydride, after which the hydrogenated ring suffers a rupture with the formation of less complex alkyl-substituted hydrocarbons which in their turn hydrogenate further, but only to the stage of 1-ring benzene hydrocarbons. The alkyl radicals are easily split off and replaced by H. The action of a catalyzer, such as $\text{Fe}_2\text{O}_3 + \text{SiO}_2$ (1:1), consists in weakening the compds. at the points where hydrogenation takes place. When anhyd. AlCl_3 is used as catalyzer, the hydrogenation can take place even without the external action of compressed H, the needed H being supplied by a portion of the original substance which suffers a complete decompn. and a condensation resulting in the production of coke. The following deductions can be made with respect to the chemical process leading to the formation of coal-tar ring compds.: While the origin of C_{10}H_8 and of its homologs is usually ascribed to various condensation reactions of simpler compds., it is very likely that the higher fractions of the neutral primary tar oil contain hydrides of condensed ring hydrocarbons which by pyrolysis, particularly in presence of nascent H, produce C_{10}H_8 and its homologs; the dehydrogenation, which takes place simultaneously, leads to formation of typical hydrocarbons with condensed rings, their skeleton being formed at the expense of the bituminous component of the coal. B. N.

Furan compounds derived from sugars. II. Some acetyl derivatives of hydroxymethylfurfural. JUNJI KARASHIMA. *Physiol.-chem. Inst. Nagasaki. Z. physiol. Chem.* 180, 241–8(1929); cf. *C. A.* 21, 3912.—Acetoxymethylfurfural (I) was prepd. in 71.4% yield by heating hydroxymethylfurfural (II) 2 hrs. on a water bath with 2 mols. anhyd. NaOAc and 2.5 mols. Ac_2O , then dilg. with H_2O and evapg. *in vacuo*. Addn. of H_2O pptd. the Ac deriv. as a brownish oil, which gradually crystd. It showed the same m. p. 55°, as the prepn. Fenton and Gostling obtained by the use of AgOAc . Attempts to oxidize it to acetoxymethylpyromucic acid were unsuccessful. Metallic oxides, e. g., CuO , Ag_2O , HgO , not only oxidized the CHO but also sapond. the Ac, yielding hydroxymethylpyromucic acid. Alk. oxidizing agents, as KMnO_4 , carried the oxidation further, yielding dehydromucic and oxalic acids. Acetoxymethylfurfuracrylic acid, m. 134°, was obtained from I and also from II by the Perkin synthesis. The aldehyde was heated 6 hrs. in an oil bath at 160–70° with 3 mols. anhyd. NaOAc and 4 mols. Ac_2O , the reaction mixt. dissolved in aq. Na_2CO_3 , extd. with AcOEt to remove unchanged aldehyde, and the acid pptd. cryst. by addn. of HCl . The yield from I was 50% and from II 33.3%. Sapon. by $\text{Ba}(\text{OH})_2$, followed by treatment with CO_2 and H_2SO_4 to remove Ba, and extn. with Et_2O , yielded 72.5% hydroxymethylfurfuracrylic acid, m. 139°. This does not sublime like its Ac deriv. When fed to rabbits, dogs and chickens, I was excreted in the urine as hydroxymethylpyromucic acid, m. 167° (evolution of gas). The recovery of acid varied from 49.7 to 73.3%. Neither the Ac deriv. nor hydroxymethylpyromucic acid was found. A. W. DOX

Pyrrole. S. M. McELVAIN AND K. M. BOLLIGER. *Org. Syntheses* 9, 78–9(1929).—Mucic acid (630 g.) and 900 cc. NH_4OH (d. 0.9) are evapd. to dryness and the powd. NH_4 salt is mixed with 350 cc. $\text{C}_2\text{H}_5(\text{OH})_2$ and, after standing overnight, the mixt. is distd., giving 37–40% of pyrrole. C. J. WEST

Kakishibu. IV. Constitution of shibuol. 3. SHIGERU KOMATSU AND NAHIKO MATSUNAMI. *Mem. Coll. Sci. Kyoto Imp. Univ. Ser. A*, 11, No. 4, 205–9(1928) (reprint).—Benzene-azo-shibuol (I) was prepd. by treating fresh shibu free from pectin with PhN_2Cl . Its tinctorial properties were compared with those of the benzene-azo derivs. of myricetin, catechin and quercetin. In dyeing properties, shibuol and I greatly resemble myricetin and its benzene-azo compd. Reduction of shibuol in NaOH with Zn dust gave gallic acid and phloroglucinol. V. Methylation of shibuol. SHIGERU KOMATSU, NAHIKO MATSUNAMI AND MASAO KURATA. *Ibid* 211–5.—Methylation of shibuol in Na_2CO_3 with Me_2SO_4 gave dimethylshibuol; in NaOH trimethylshibuol (II) was obtained. Methylating in d. l. NaOH at a high temp. gave tetramethylshibuol (III) and II. In an acidic medium, methylation gave III. II treated with MeI gave III. Acetylation of II gave monoacetyltrimethylshibuol. These reactions indicate the presence of at least 4 free OH groups in the mol. of shibuol. R. C. ROWLANDS

Attempt to prepare γ -isoleidole. GORFREY W. FENTON AND CHRISTOPHER K.

INGOLD. Univ. Leeds. *J. Chem. Soc.* 1928, 3295-7.—F. and I. attempted to apply the reaction of Holmes and I. (*C. A.* 20, 2839) to the prepn. of ψ -isindole according to the following scheme: $o\text{-C}_6\text{H}_4(\text{CH}_2\text{Br})_2 \longrightarrow \text{C}_6\text{H}_4(\text{CH}_2)_2\text{NSO}_2\text{Ar} \longrightarrow \text{C}_6\text{H}_4\text{CH}_2\text{N:CH} + \text{SO}_2 + \text{ArH}$ but without success. 26.4 g. $o\text{-C}_6\text{H}_4(\text{CH}_2\text{Br})_2$ was

added to a cold suspension of 17.0 g. $p\text{-MeC}_6\text{H}_4\text{SO}_2\text{NH}_2$ and 10 g. Na_2CO_3 in a soln. of NaOEt (from 4.5 g. Na in 150 cc. EtOH). Gentle warming followed by boiling for 2 hrs., cooling, mixing with H_2O , nearly neutralizing with AcOH , and crystg. from EtOH yielded 13 g. $2\text{-}p\text{-toluenesulfonyldihydroisindole}$ (I), m. 176° . $2\text{-Benzenesulfonyldihydroisindole}$ (II), m. 140° . I distd. in N_2 with 85% KOH gave a distillate consisting of MePh and a small amount of basic product; the alk. residue contained tar, sulfite, no p -cresol. The picrate of the base, greenish yellow leaflets from EtOH , m. $196\text{--}7$ (decompn.) identified it as dihydroisindole (v. Braun, *C. A.* 17, 390). The same picrate was obtained from II. Since this result was unexpected it was confirmed in the following way: 1-Methyldihydroisindole (III) (Gabriel and Neumann, *Ber.* 26, 705(1893)) was converted into $2\text{-}p\text{-toluenesulfonyl-1-methyldihydroisindole}$ (IV), which on distn. with 75% KOH gave PhMe , sulfite, tar, no p -cresol but III, which was identified by conversion to the nitrosamine, m. 100° and its conversion into IV.

DAVID DAVIDSON

Phenylindene series. I. The β,β -diphenylhydrindone. CHARLES MOUREU, CHARLES DUFRAISSE AND PAUL M. DEAN. College de France, Paris. *Bull. soc. chim.* 43, 1367-71(1928).— $\text{Ph}_2\text{CCH}_2\text{CO}_2\text{H}$ may be prepd. (1) by condensing Ph_2CBr and the $\text{CHNa}(\text{CO}_2\text{Et})_2$ or (2) condensing Ph_2COH with $\text{CH}_2(\text{CO}_2\text{H})_2$. The latter method is the more practical and gave a 76% yield. The condensation of this acid by itself in H_2SO_4 gave β,β -diphenylhydrindone (I), which fuses at $129\text{--}30^\circ$ and gives an oxime, m. $155\text{--}6^\circ$. II. Passage of β,β -diphenylhydrindone into α,β -diphenylindone. CHARLES MOUREU, CHARLES DUFRAISSE AND FRANÇOIS BAYLOCO. *Ibid* 1371 80. —Br on I gave its *mono-Br* (II), m. $154\text{--}5^\circ$, and *di-Br deriv.* (III), m. 205° . PBr_3 on I or II gave a mixt. of II and III. PBr_3 did not react with III. Heating III in a closed tube at 170° gave 8% α,β -diphenylindone (IV), m. $151\text{--}2^\circ$. Dehydrogenating I gave IV. Heating II in a closed tube up to 200° gave 75% IV. Heating III gave IV easily and in good yield. Treating I with $\text{C}_6\text{H}_5\text{NO}_2$ and EtONa in abs. alc. gave the α -diketone monoxime, m. 220° . $\text{Ph}_2\text{CCH}_2\text{COCl}$ prepd. from the acid and SOCl_2 is changed to I by AlCl_3 in CS_2 . III. Some derivatives of α,β -diphenylindone. CHARLES MOUREU, CHARLES DUFRAISSE AND MARIUS BADOCHÉ. *Ibid* 1381-8. —Heating IV and PCl_5 gave dichlorodiphenylhydrindone (V), m. $132\text{--}3^\circ$. Treating V with Cu in C_6H_6 and Mg in Et_2O gave IV. Alc. KOH removed about 0.5 of the Cl from V but the product was not studied further. Treating IV in Et_2O with Na and decompg. the excess Na with H_2O gave a compd., m. $129\text{--}30^\circ$ consisting of IV to which 1 mol. H_2O had been added. P_2O_5 and ZnCl_2 removed the H_2O from this compd. giving IV. From the mother liquor of the reaction with Na, there was obtained 23% of the compd. $\text{C}_{14}\text{H}_{10}\text{O}$, which is IV contg. 2 extra H. Heating this compd. with PbO gave IV. Treating IV in AcOH with reduced Fe gave the same reduced product.

R. C. ROBERTS

Synthesis of phenylindones from nitriles of the cinnamic acid series. P. FEFIEFFER, H. BEHR, H. KÜBLER AND H. RÜPING. Univ. Bonn. *J. prakt. Chem.* 121, 85-96 (1929).— $\text{O}_2\text{NC}_6\text{H}_4\text{C}(\text{CN})\text{:CHPh}$ (the *cis* form, since it is not esterified by MeOH and HCl), warmed on the H_2O bath with concd. H_2SO_4 , yields 4'-nitro-2-phenylindone, red, m. $156\text{--}7^\circ$; the concd. H_2SO_4 soln. is brownish red. $\text{O}_2\text{NC}_6\text{H}_4\text{C}(\text{CN})\text{:CHC}_6\text{H}_4\text{Cl}$ (*cis* form, m. 182°) and concd. H_2SO_4 give 4'-nitro-5-chloro-2-phenylindone, deep red, m. 195° , and the acid amide, $\text{O}_2\text{NC}_6\text{H}_4\text{C}(\text{CONH}_2)\text{:CHC}_6\text{H}_4\text{Cl}$, m. 230° . $p\text{-NCC}_6\text{H}_4\text{:CH}_2\text{CN}$ and BzH , condensed by heating with a few drops of piperidine at $100\text{--}10^\circ$, give p,μ -dicyanostilbene, m. $146\text{--}7^\circ$; with MeOH and HCl this yields *Me* μ -cyanostilbene-*p*-carboxylate, m. $146\text{--}7^\circ$; *Et ester*, m. $133\text{--}4^\circ$; with concd. H_2SO_4 there results quant $2\text{-phenylindone-4-carboxamide}$, orange, m. 198° . p,μ -Dicyano-*p'*-methoxystilbene, greenish yellow, m. $161\text{--}2^\circ$; MeOH and HCl give *Me* μ -cyano-*p'*-methoxystilbene-*p*-carboxylate, light yellow, m. 158° . $p\text{-NCC}_6\text{H}_4\text{C}(\text{CN})\text{:CHC}_6\text{H}_4\text{NMe}_2$, warmed 1 hr. on the H_2O bath with concd. H_2SO_4 , gives a diamide (?), yellow-brown, m. 268° ; heating this with 10% NaOH about 10 hrs. gives the monoamide of *p'*-dimethylaminostilbene μ,β -dicarboxylic acid, light yellow, crystg. with 1 H_2O ; the anhyd. form is reddish orange, m. 264° ; *Ba salt*, light yellow needles; *Me ester*, canary-yellow, m. 217° ; *Et ester*, canary-yellow, m. 185° .

C. J. WIST

1-*o*-Chlorophenyl-3-methyl-5-pyrazolone and its derivatives. Z. TOMASIK. *Roczniki Chem.* 3, 345-8(1928).— $o\text{-ClC}_6\text{H}_4\text{NHNH}_2$ condenses with $\text{AcCH}_2\text{CO}_2\text{Et}$ to yield 1-*o*-chlorophenyl-3-methyl-5-pyrazolone, m. 190° (4-benzylidene deriv., m. 157° ; 4-*o*-nitro-

benzylidene deriv., m. 160°), which when condensed with *o*-O₂NC₆H₄CHO yields *o*-nitrophenylbis-[1-*o*-chlorophenyl-3-methyl-5-pyrazolonyl]methane, m. 249°. B. C. A.

Tautomerism of some heterocyclic compounds. EMIL FROMM, REGINE KAPPELLER-ADLER, W. FRIEDENTHAL, L. STANGEL, J. EDLITZ, E. BRAUMANN AND J. NUSSBAUM. Lab. med. Chemie zu Wien. *Ann.* 467, 240-74(1928).—This work is an extension of the previous work on the tautomerism of aminooxazolines (*C. A.* 20, 2160). Amino-thiazolines react with thiocarbimides, yielding 2 series of thiocarbamides according to the conditions; no tautomerism is found in either the thiazole, oxazole or triazole series, in the 1st 2 cases presumably because of the aromatic nature of the ring systems. 2-Amino-5-chloromethyloxazoline (I), NH₄Cl and EtOH, heated 3 hrs. at 100° give β -chloro- β' -guanidinoisopropyl alc.-HCl, m. 112°; *picrate*, m. 147°; *tri-Bz deriv.*, m. 178°, identical with the compd. previously described as 2- μ -amino-5-aminomethylimidazoline tetrabenzoate (F. and Pirk). Heating I with dil. NH₄OH at 100° 4 hrs. gives 2- μ -amino-5-aminomethyloxazoline, oily, whose *picrate*, m. 172°; the *chloroplatinate* is red. I, NaOH and PhSO₂Cl give 5-chloromethyl-2- μ -iminooxazolinyl 3-benzenesulfonate, m. 111° (2-Bz deriv., m. 152°), hydrolyzed by cold dil. H₂SO₄ to 5-chloromethyloxazolidonyl 3-benzenesulfonate, m. 106°. The reaction product of NCNNa₂ and HOCH₂CH(OH)CH₂Cl, shaken with NaOH and PhSO₂Cl, gives the tribenzenesulfonate, m. 158°, of 2- μ -amino-5-hydroxymethyloxazoline, which does not react with BzCl and is stable towards dil. H₂SO₄. NCNHNa and HOCH₂CH₂CH₂Cl give an oily product which, shaken with NaOH and BzCl, gives 2- μ -amino-5-methyloxazoline dibenzoate, m. 75°; with PhNCS this gives 5-methyl-2-iminooxazolinyl-3-phenylthiourea (II), m. 98°; when this is heated above its m. p. or in EtOH for 2 hrs., the isomeric compd. (III), m. 152°, is formed, while hydrolysis with dil. H₂SO₄ gives 5-methyloxazolidonyl-3-phenylthiourea (IV), m. 114°

I, PhCH₂SH and NaOH, heated 2 hrs. in EtOH, give 2- μ -amino-5-thiobenzylmethyl-oxazoline (V), m. 92° (*di-Bz deriv.*, m. 112°); with PhNCS this gives 5-thiobenzylmethyl-2-iminooxazolinyl-3-phenylthiourea, m. 89°; heating in EtOH several hrs. gives the isomeric 5-thiobenzylmethyl-oxazolinyl-2-phenylthiourea, m. 129°; hydrolysis with dil. H₂SO₄ gives 5-thiobenzylmethyl-oxazolidonyl-3-phenylthiourea, m. 107°. V and CH₂:CHCH₂NCS give the corresponding 3-allylthiourea, m. 87°; heating with AmOH 4 hrs. gives 5-thiobenzylmethyl-oxazolinyl-2-allylthiourea, m. 100°, while dil. H₂SO₄ gives 5-thiobenzylmethyl-oxazolidonyl-3-allylthiourea, m. 59°. Aminothiazoline (VI) (*di-Bz deriv.*, m. 182°) and *p*-MeC₆H₄SO₂Cl with NaOH give 2-iminothiazolinyl 3-*p*-toluenesulfonate, m. 143°, hydrolyzed by H₂SO₄ to thiazolidonyl 3-toluenesulfonate, m. 158°. PhNCS in the cold converts VI into 2-iminothiazolinyl-3-phenylthiourea (VII), m. 60°, then resolidifies at 80° and again, m. 129° (*picrate*, m. 230°, explodes over 300°); dil. H₂SO₄ gives thiazolidonyl-3-phenylthiourea, m. 103°. PhNCS, VI and NaOH in hot EtOH gives thiazolinyl-2-phenylthiourea, m. 130°. 2-Iminothiazolinyl-3-allylthiourea (VIII), m. 71°, resolidifies at 79° and again m. 142°; hydrolysis gives thiazolinyl-2-allylthiourea, m. 111°. Hot CH₂:CHCH₂NCS gives thiazolinyl-2-allylthiourea, m. 143°. Detns. of the mol. wts. of VII and VIII in PhOH give values which are approx. 0.5 of the theoretical, indicating that they are additive compds. This possibility is discounted by the formation of thiazolidones by hydrolysis and also by the observation that Ph₂NCSNHMe gives a similar low value. C₂H₄(NH₂)₂ and CH₂:CHCH₂NCS give ethylenedi-allylthiourea, m. 102°; Br in CHCl₃ transforms this into ethylenedi[aminobromomethylthiazoline] (IX), m. 161°; Ag₂O gives the corresponding glycol, m. 108°; the *dinitrile*, m. 118° and the *dicarboxylic acid*, m. 147°. The action of EtOH-KOH on IX gives ethylenedi[aminomethylenethiazoline], m. 153°. Phenylthiazylamine (*Bz deriv.*, m. 124-5°; *benzylidene deriv.*, m. 127°; *p*-toluenesulfonate, m. 150°), heated with PhNCS on the H₂O bath 2-3 hrs., gives 5-phenylthiazolyl-2-phenylthiourea, yellow, m. 213°. Methylthiazylamine (*di-Bz deriv.*, m. 110°) gives 5-methylthiazolyl-2-phenyl- and -2-allylthiourea, m. 172° and 178°, resp., under all conditions. PhCH₂COBr and NCNHNa in H₂O give 2-amino-5-phenyloxazole, m. 216° (*Bz deriv.*, m. 182°; *Ac deriv.*, yellow, m. 134°); PhNCS gives as the only product 5-phenyloxazolyl-2-phenylthiourea, m. 195°, which is stable toward H₂SO₄. 3-Amino-5-anilino-1-phenyltriazole (*Bz deriv.*, m. 105°) yields the 3-phenylthiourea, m. 194°, and the 3-allylthiourea, m. 191°. 3-Amino-5-anilino-1,2,4-triazole, m. 163°, gives the corresponding 3-phenylthiourea, m. 203°, and the 3-allylthiourea, m. 133°. The phenyl-

thiourea and *allylthiourea* derivs. of phenylguanazole, m. 252° and 220°, resp. Piperazinodi[phenylthiourea], m. 263°; the *diallylthiourea* deriv., m. 153°; the *di*[phenylbenzylthiourea], m. 102°. *Piperasinodi*[bromomethylthiazoline], m. 156°, from the allyl deriv. and Br in CHCl₃ (*di-HCl* salt, m. 248°); with EtOH-KOH this gives the *di*[methylenthiazoline], m. 166°, while *p*-MeC₆H₄SNa gives the *di*[thiocresylmethylthiazoline], m. 135°. HBr at 100° converts the allyl deriv. into the *di*[methylthiazoline], m. 120° (*di-HBr* salt, does not m. 280°). 1-Phenyl-5-thioltriazole-3-phenylthiourea, m. 264°; the 5-thiolbenzyl deriv., m. 188°; the 5-thiolmethyl deriv., m. 178°. 1-Phenyl-5-thiolbenzyltriazole-3-allylthiourea, m. 129°; the 5-thiolmethyl deriv., m. 138°. 1-Phenyl-3-thiolbenzyltriazole-5-phenylthiourea, m. 154°; the 5-allyl deriv., m. 138°. 1-Phenyl-5-amino-3-thiolbenzyltriazole dibenzoate, m. 125°. PhNH₂ and di-Me cyanamidodithiocarbonate give 5-amino-3-methylthiol-1-phenyltriazole, m. 105°. *Bz* deriv., m. 118°. The dibenzyl ester and N₂H₄·H₂O give 3-amino-4-benzylthio triazole, m. 109°; *HCl* salt, m. 100°; dibenzoate, m. 148°. 5-Benzylthioltriazolyl-3-phenylthiourea and the -3-allylthiourea, m. 155° and 116°, resp. 1-Phenyl-3-amino-5-methylthioltriazole (*sulfone* deriv., m. 304° (not sharply)) yields a *toluenesulfonate*, m. 142°. Oxidation of 1-phenyl-3-amino-5-benzylthioltriazole with KMnO₄ in AcOH gives a *compd.*, C₁₀H₁₂N₂S₂, m. 140°, probably an azo compd.

C. J. WEST

Organomagnesium derivatives. IV. The diphenylisochromans. A. GARCIA BANÚS. Facultad Ciencias Barcelona. *Anales soc. españ. fis. quim.* 26, 372 (1928).—Under certain definite conditions the reaction between PhCH₂MgCl and BzH proceeds in an anomalous manner. The interpretation of the course of this abnormal reaction depends logically on the nature of the resulting products; from the complex mixt. can be isolated, in good yield, PhCH(OH)CH₂Ph (I) (sometimes, depending on the treatment of the mixt., there is obtained PhCH:CHPh (II)), a substance (III) originally designated diphenylisochroman but which, for reasons given below, is now called *α*-diphenylisochroman, and, in smaller amount, an unsatd. substance (IV) called diphenylisochromene. It was assumed that the Grignard reagent reacts in an *o* quinoid form and with 2 mols. BzH gives a compd. *o*-PhCH(OH)C₆H₄CH₂CH(OH)Ph (V) which, when the reaction mixt. is worked up, loses H₂O to form III, but later work showed that this hypothesis is untenable. Nor can the abnormal reaction be explained by the series of reactions proposed by Marshall and confirmed by the author and Medrano (*C. A.* 18, 2144). Before attempting to explain the mechanism of the abnormal reaction it was imperative, therefore, to establish with certainty the structure of the products formed. The chief difficulty is that they do not readily form derivs. To be sure, it had been found that *α*-III can be converted into *α*-diphenylindene (VI) but this is far from being decisive proof of the structure of III. The O bridge is not ruptured by shaking *α*-III in C₆H₆ with K-Na alloy, but this failure to react with K at least confirms the absence of HO and C:O groups. As had already been found, *α*-III cannot be acetylated with Ac₂O in the presence of NaOAc or C₆H₅N or with boiling AcCl, but in the presence of traces of H₂SO₄ it is so sensitive to Ac₂O that unless the reaction is carried out with great care only resins and secondary products are obtained. Of the 2 resulting substances, m. 114-5° (VII) and 174-5°, originally thought to be acetates the latter is really VI. The relative amounts of the 2 compds. formed varies widely with the exptl. conditions. With very little heating and very little H₂SO₄ the *α*-diphenylisochroman acetate (VII) is obtained in good yield but with too much heating or an excess of H₂SO₄ only VI can be isolated; in any case there is always formed a large amount of resin from which VI can be obtained by distn. The compn. AcO content and mol. wt. of VII indicate that it has the structure *o*-PhCH(OAc)C₆H₄CH₂CH(OAc)Ph; with concd. H₂SO₄ it gives the green halochromism characteristic of *α*-III. VII is readily saponifd. to a *carbinol* which likewise shows the characteristic green halochromism with H₂SO₄ but, unlike *α*-III, gives the characteristic reactions of an alc., reacting with SOCl₂ and with Na and readily regenerating VII on simple boiling with Ac₂O. The compn. of this *diphenylisochroman hydrate* corresponds to formula V and it seemed possible that it might be present, as the primary product of the abnormal reaction between PhCH₂MgCl and BzH, in the resins which, on distn. *in vacuo*, yield III. To be sure, it itself distn. unchanged *in vacuo*, but there was a possibility that the resins contain a substance which catalyzes the dehydration and cyclization of V on distn. Of such catalysts, the one most likely to be present was a Mg salt, and as a matter of fact distn. of V *in vacuo* with a small quantity of MgCl₂ and Mg(OAc)₂ converts it into a mixt. of isomeric *α*- and *β*-III; the *β*-compd. is also formed in the abnormal reaction between PhCH₂MgCl and BzH but had hitherto escaped detection. With KMnO₄ in Me₂CO, V gives the same products as *α*-III, viz., BzOH, *o*-BzC₆H₄CO₂H and a neutral compd. (VIII), which from its compn. and

properties seems to be *o*-benzoylbenzil, $\text{BzC}_6\text{H}_4\text{COBz}$. Although the acetate and benzoate of I are readily obtained with Ac_2O and BzCl , resp., from the addn. product, $\text{PhCH}(\text{OMgCl})\text{CH}_2\text{Ph}$, of PhCH_2MgCl and BzH , the product of the abnormal reaction reacts entirely differently, giving only resins, so that the presence of V in this product cannot be detected by this means. III is obtained, as has been repeatedly described, by slowly adding PhCH_2MgCl in Et_2O with stirring to cold BzH , decomp. with dil. AcOH , washing the Et_2O layer with H_2O and Na_2CO_3 , evapg., distg. the resulting resin *in vacuo* and crystg. the fraction *b.* $230-50^\circ$ from Et_2O . There is thus obtained a product which is apparently homogeneous but m. indefinitely at $90-100^\circ$ and by means of C_6H_6 -petroleum ether can be sepd. into α - and β -III; both melt at practically the same temp. ($110-1^\circ$), show the same characteristic emerald-green halochromism with concd. H_2SO_4 , give the same VII on acetylation and yield the same products with KMnO_4 in Me_2CO ; the only difference thus far observed is in the cryst. form when they sep. from C_6H_6 -petroleum ether; from Et_2O both cryst. in apparently the same form. The β -compd. may itself sep. in 2 forms, m. $110-1^\circ$ and $136-7^\circ$ (γ -form) mutually transformable into each other. The change $\gamma \rightarrow \beta$ can be effected by simple crystn. from Et_2O and in 2 cases occurred spontaneously at room temp., once under a satd. soln. in C_6H_6 -petroleum ether and once in dry form in a sealed tube. The conditions for obtaining the γ -form have not been established; it has been obtained only but not always from C_6H_6 -petroleum ether; on several occasions it has been observed that if the β -form seps. and then the crystals and mother liquors are heated for a time and cooled slowly the γ -form seps. out; perhaps the β -form is stable at room temp., the γ -form above 70° (b. p. of the C_6H_6 -petroleum mixt.). IV on catalytic hydrogenation gives β -III. Assuming that the structure assigned to III is correct, there are 4 possible stereoisomeric forms (IX-XII), of which IX and XI, on the one hand, and X and XII, on the other, are mirror images and, therefore, can be isolated only as the racemates. It would be expected, however, that the 2 racemates would yield different acetates and carbinols (XIII, XIV, $\text{R} = \text{Ac}$ or H); possibly in the acetylation there occurs a sort of racemization resulting in the formation of the more stable form exclusively. This is the only exptl. fact thus far observed which cannot be explained on the basis of the structure assigned to the III and as the structure of these compds. is of fundamental importance in the interpretation of the abnormal reaction between PhCH_2MgCl and BzH , efforts must be made to synthesize the III or one of their close derivs. (With L. MEDRANO.) VII, m. $117-8^\circ$, mol. wt. in C_6H_6 $359-63$, is obtained in 2.5 g. yield from 4.5 g. α -III in 18 g. freshly distd. Ac_2O treated with 9 cc. Ac_2O contg. 1 drop concd. H_2SO_4 ; the mixt., which becomes quite warm and yellow, is heated on the H_2O bath below 45° until all the III has dissolved (about 10 mins.), allowed to stand 24 hrs. at room temp., dild. with 150 cc. Et_2O and 300 cc. H_2O , cooled with ice and neutralized to phenolphthalein with NaOH and, at the end, with Na_2CO_3 ; the Et_2O layer is washed with H_2O , dried with CaCl_2 , concd. to about 20 cc., dild. hot with petroleum ether and cooled, and the crystals which sep. (3 g.) are recrystd. from Et_2O . V, from VII in boiling alc. contg. a drop of phenolphthalein treated with alc. KOH to permanent alky., m. $114-5^\circ$. With the calcd. quantity of Beckmann's mixt., V is for the most part not attacked, giving only a little BzH , while with an excess of the reagent are formed the same products as had already been obtained from III with CrO_3 - AcOH . Boiled 2 hrs. in Me_2CO with 2 g. KMnO_4 , 2 g. V gives 0.4-0.5 g. $\text{BzOH} + o\text{-BzC}_6\text{H}_4\text{CO}_2\text{H}$ and 0.2 g. VIII, lemon-yellow, m. 94° . The dehydration of V into $\alpha + \beta$ -III can also be effected by merely heating the V in an open tube with the $\text{Mg}(\text{OAc})_2\text{-MgCl}_2$ catalyst 1 hr. at 230° . On refluxing with 1:1 H_2SO_4 the dehydration proceeds entirely differently; there are obtained 2 products, sepd. by careful crystn., both m. $108-10^\circ$ (mixed m. p. $92-4^\circ$), which do not show halochromism with concd. H_2SO_4 , and are supposed to have the structure $\text{PhCH}(\text{OH})\text{C}_6\text{H}_4\text{CH}:\text{CHPh}$. α -III seps. in fine silky needles, β -III in prisms, and they are sepd. by floating off the α -compd. 1,2-Diphenylethanol acetate (tolylene hydrate acetate), from PhCH_2MgCl in Et_2O slowly added to BzH in Et_2O , refluxed 0.5 hr., cooled, treated with Ac_2O and refluxed, sirupy liquid (17 g. from 30 g. PhCH_2Cl), *b.* $202-5^\circ$, decompd. by boiling alc. KOH into I and KOAc . Benzoxide, similarly obtained with BzCl (25 g. from 30 g. PhCH_2Cl), m. 70° . (With M. DÍAZ ROLDÁN.) 1-Anisyl-2-phenylethanol acetate (*p*-anisylbenzylcarbinol acetate) (35 g. from 27 g. PhCH_2Cl with Mg , $\text{MeOC}_6\text{H}_4\text{CHO}$ and Ac_2O), m. $81-2^\circ$, yields *p*- $\text{MeOC}_6\text{H}_4\text{CH}:\text{CHPh}$ on sapon. with boiling dil. H_2SO_4 , whereas when 5 g. is slowly treated in boiling alc. with 10% NaOH to permanent alky. it gives 3.5 g. of the free carbinol (XIII), m. $60-1^\circ$. Tolyene hydrate urethan (4 g. from 5 g. I mixed and allowed to stand some time with 4.5 g. PhNCO), m. $94-5^\circ$. Attempts to prep. the urethan of XIII in the same way gave a substance isomeric with and having the same

m. p. (135-6°), cryst. form and solubilities as *p*-MeOC₆H₄CH:CHPh but depressing the m. p. of the latter.

C. A. R.

Synthetical experiments in the isoflavone group. III. Synthesis of genistein. WILSON BAKER AND ROBERT ROBINSON. *J. Chem. Soc.* 1928, 3115-18; cf. *C. A.* 22, 2356.—Reduction of 3,4,5-(MeO)₃C₆H₂COCl in C₆H₅Me₂ by H in the presence of BaSO₄ gave 3,4,5-(MeO)₃C₆H₂CHO (I). I, PhCONHCH₂CO₂H and AcONa heated gave the azlactone. NaOH followed by SO₃ and by HCl gave 3,4,5-(MeO)₃C₆H₂CH₂COCO₂H (II). II and H₂NOH.HCl in aq. NaOH at 50° gave the oxime by HCl pptn. after 12 hrs. The oxime with Ac₂O gave 3,4,5-(MeO)₃C₆H₂CH₂CN (III), m. 77°. By dissolving III in 95% H₂SO₄ and pouring on ice after 24 hrs., (MeO)₃C₆H₂CH₂CONH₂, m. 121°, was obtained by CHCl₃ extrn. III and 4,5,1,3-(MeO)₂(HO)₂C₆H₂ in anhyd. Et₂O with HCl and ZnCl₂ at 0° gave 2,6-dihydroxy-3,4-dimethoxyphenyl 3,4,5-trimethoxybenzyl ketone (IV), m. 162°. No isomer could be detected. AcONa, Ac₂O and IV at 180° for 6 hrs. gave the Ac deriv. which hydrolyzed gave 5-hydroxy-6,7,3',4',5'-pentamethoxy-2-methylisoflavone (2-methylirigenin 7,3'-di-Me ether) (V), m. 179-80°; Ac deriv., m. 232-3°. Boiling V in MeOH with Me₂SO₄ and KOH gave 5,6,7,3',4',5'-hexamethoxy-2-methylisoflavone (2-methylirigenin tri-Me ether) (VI), m. 166°. Decompn. with alkali at 180° gave 3,4,5-(MeO)₃C₆H₂CH₂OH (antiarol) and 3,4,5-(MeO)₃C₆H₂CH₂CO₂H. Demethylation of V with HI at 130° for 1 hr. gave 5,6,7,3',4',5'-hexahydroxy-2-methylisoflavone (2-methylirigenol) (VII), m. 325° (decompn). Me₂SO₄ in H gave VI from VII. VII is similar in appearance and behavior to irigenin but is more sol. in org. solvents. Cinnamoylation of IV and alk. hydrolysis gave 5-hydroxy-6,7,3',4',5'-pentamethoxy-2-styrylisoflavone (VIII), m. 270°; Me ether, m. 214-5°. Alk. hydrolysis of irigenin gave iridic acid (IX), m. 118°. The Me ester of IX in NH₄OH after 24 hrs. gave 3,4,5-HO(MeO)₂C₆H₂CH₂CONH₂ (iridamide), m. 113°. PhCH₂CN and C₆H₅(OH)₂OMe in anhyd. Et₂O with HCl and ZnCl₂ at 0° gave 2,4-HO(MeO)₂C₆H₂COCH₂Ph (X), which by heating with Ac₂O and AcONa at 180° for 18 hrs. gave 7-methoxy-2-phenylisoflavone. From the NaOH washings was isolated 4,2-HO(MeO)₂C₆H₂COCH₂Ph (XI), m. 113°; Ac deriv., m. 68°. About 3 parts of X to 1 of XI were obtained. 3,5-HO(MeO)₂C₆H₂Me and PhCH₂CN similarly gave a mixt. sepd. mech., of plates of 4,2,6-HO(MeO)₂MeC₆H₂COCH₂Ph (XII), m. 93° Ac deriv., m. 88°, and needles of 2,4,6-HO(MeO)₂MeC₆H₂COCH₂Ph (XIII), m. 110°. Ac₂O and AcONa with XIII at 180° for 12 hrs. gave a product with no AcO group, 7-methoxy-2,5-dimethylisoflavone, m. 165°. About 17% as much XII as XIII was produced. 4,5,1,3-(MeO)₂(HO)₂C₆H₂ reacts persistently in position 2. The other phenolic ethers investigated were not as specific. IV. Synthesis of 2-methylirigenol. *Ibid.* 1929, 152-61; cf. *C. A.* 20, 196; 21, 246.—Methylation of 5,7-dihydroxy-4'-methoxy-2-styrylisoflavone with Me₂SO₄, MeOH and aq. KOH gave 5-hydroxy-7,4'-dimethoxy-2-styrylisoflavone (I), m. 245-6°, insol. in dil. aq. KOH. Ac deriv. (II), m. 203-4°. Hydrolysis of II gives I. Oxidation of II by KMnO₄ in Me₂CO at -10 to -15° was unsuccessful. I with Me₂SO₄ and aq. NaOH in Me₂CO gave 5,7,4'-trimethoxy-2-styrylisoflavone (III), m. 193°. Similarly 5-hydroxy-7,4'-dimethoxy-2-styrylmethylisoflavone gave 5,7,4'-trimethoxy-2-styryl-6(?)'-methylisoflavone, m. 211° (shrinking). Aq. KMnO₄ oxidation of III in C₆H₅N at 85° gave 5,7,4'-trimethoxyisoflavone-2-carboxylic acid (IV), m. 237° (sharp but decompn. followed). Heating IV above its m. p. gave 5,7,4'-trimethoxyisoflavone (genistein tri-Me ether) (V), m. 162-3°, needles or rhombic plates. Recovered V in AcOH demethylated with HI by boiling was acetylated.

Hydrolysis gave 5,7,4'-trihydroxyisoflavone (genistein, prunetol), softened 284°, m. 290-1°, mixed m. p. with natural genistein the same. The Ac deriv. and di-Me ether were the same as from the natural product. FOSTER DEE SNELL

Anthoxanthins. VIII. Synthesis of morin and of 5,7,2',4'-tetrahydroxyflavone. ROBERT ROBINSON AND KRISHNASAMI VENKATARAMAN. Univ. of Manchester. *J. Chem. Soc.* 1929, 61-7; cf. *C. A.* 21, 93.—A mixt. of 6 g. ω -methoxyphloracetophenone, 50 g. [2,4-(MeO)₂C₆H₃CO]₂O and 12 g. 2,4-(MeO)₂C₆H₃CO₂Na, heated 4 hrs. at 180-5°, and the product hydrolyzed by boiling with KOH in dil. EtOH, gives 7.3 g. of morin 3,2',4'-tri-Me ether (I), pale straw, m. 132°; FeCl₃ gives an olive-green color; penta-Me ether, m. 155-7°; the crude product from which I was obtained, on boiling with Ac₂O and C₆H₅N, gives *O*-2,4-dimethoxybenzoyl-*O*-acetylmorin 3,2',4'-tri-Me ether, m. 170°. Hydrolysis of I with HI and Ac₂O gives morin, crystg. with 1 H₂O, which is not lost at 130° in high vacuum; this is identical with natural morin as far as could be ascertained by direct comparison. Condensation of phloracetophenone, [2,4-(MeO)₂C₆H₃CO]₂O and 2,4-(MeO)₂C₆H₃CO₂Na, followed by hydrolysis, yields 5,7-dihydroxy-2',4'-dimethoxyflavone, pale yellow, m. 258-9°; HI and Ac₂O give 5,7,2',4'-tetrahydroxyflavone, m. 332-5° (decompn.), which showed little resemblance to loto-flavin (cf. Dunstan and Henry, *Phil. Trans* 194, 515(1901)). IX. Syringetin. TOM HEAP AND ROBERT ROBINSON. *Ibid* 67-73.—Condensation of ω -benzoyloxyphloracetophenone (I), [3,4,5-(MeO)₃C₆H₂CO]₂O and 3,4,5-(MeO)₃C₆H₂CO₂Na, by heating 9.5 hrs. at 180-5°, followed by hydrolysis with KOH, gives myricetin 3',4',5'-tri-Me ether (II), pale yellow, m. 290-3°; the yellow concd. H₂SO₄ soln. has a weak green fluorescence; FeCl₃ gives a deep brownish olive-green color; the Pb salt is a deep yellow. The *O*-tri-Ac deriv., nearly white, m. 195-5.5°. The action of fuming H₂SO₄ on II at 40° gives a monomethylmyricetinsulfonic acid, yellow, does not m. 330°; FeCl₃ gives an intense dark olive-green color; the yellow concd. H₂SO₄ soln. exhibits a green fluorescence. Syringic acid and BzCl in alkali give 49% of the *O*-Bz deriv., m. 229-32°; chloride, m. 116.5-8°; the anhydride could not be obtained pure. *O*-Benzylsyringic anhydride, m. 112-3°, results in 118 g. yield from 144 g. of the acid in 500 cc. Et₂O and 53 g. C₆H₅N with 74 cc. SOCl₂ in Et₂O; with I in the usual way there results syringetin 4'-benzyl ether, brownish orange, m. 240-1°; FeCl₃ gives an olive-green color; Pb(OAc)₂ gives a flocculant yellow ppt. The tri-Ac deriv., m. 191-4°. Prolonged boiling of the ether with concd. HCl and EtOH gives syringetin(5,7,4'-trihydroxy-3',5'-dimethoxyflavonol), pale yellow, m. 288-9°; concd. H₂SO₄ colors the crystals orange and gives a yellow soln. with a green fluorescence; alk. solus. are deep yellow; in dyeing properties it resembles isorhamnetin, of which it is a MeO deriv. *Tetra-Ac deriv.*, m. 224-6°. Me₂SO₄ converts it into myricetin hexa-Me ether, m. 159-61°. X. Synthesis of gossypetin and of quercetagetin. WILSON BAKER, RYUZABURO NODZU AND R. ROBINSON. *Ibid* 74-84.—Quercetagetin (I) occurs in the flowers of the African marigold, *Tagetes patula*, while gossypetin (II) occurs in the flowers of the Indian cotton plant, *Gossypium herbaceum*; both are derivs. of 1,3,4,5-C₆H₂(OH)₄. 1,2,3-C₆H₃(OH)₃ (50 g.), 240 g. K₂CO₃ and 300 cc. dry Me₂CO was refluxed in a H atm. for 30 hrs., 210 g. of PhCH₂Cl being gradually introduced, with the formation of 450 g. 1,2,3-tribenzyl-oxybenzene (III), m. 70°. HNO₃ (40 cc., d. 1.19), added to 80 g. III in 800 cc. AcOH at 40° and kept at room temp. for 4 hrs., gives 15 g. of the 5-NO₂ deriv., m. 139°; addn. of a 2nd lot of 40 cc. HNO₃ to the filtrate gives 30 g. 2,6-dibenzyl-oxy-*p*-benzoquinone, yellow, m. 201-2°; reduction with Zn and H₂SO₄ gives 2,6-dibenzyl-oxyquinol, m. 116-7°, which with alk. Me₂SO₄ gives 2,6-dibenzyl-oxy-1,4-dimethoxybenzene, m. 82-3°. Hydrolysis with HCl in AcOH gives 2,5-dimethoxyresorcinol, pale brownish yellow, m. 61-2° (with 2 H₂O), m. anhyd. 86-8°. The identity of this with iretol Me ether was not definitely established. Condensed with MeOCH₂CN by HCl in Et₂O there results 2,4-dihydroxy- ω ,3,6-trimethoxyacetophenone, m. 150-1° (FeCl₃ gives a deep bluish brown color), which in turn gives with K veratrate and veratric anhydride, followed by hydrolysis, 7-hydroxy-3,5,8,3',4'-pentamethoxyflavone(*O*-pentamethylgossypetin), yellow, m. 253-4°; with HI this gives II, yellow, m. 310-4°, identical with the natural specimen. The identity was further confirmed by prepn. of the hexa-Ac and hexa-Me deriva. 2,6,3,4-(HO)₂(MeO)₂C₆H₂COCH₂OMe with veratric anhydride as above gives 5-hydroxy-3,6,7,3',4'-pentamethoxyflavone (*O*-pentamethylquercetagetin), pale yellow, m. 159-60°; FeCl₃ in excess gives an intense dull olive-green color; the deep yellow concd. H₂SO₄ soln. becomes cherry-red on addn. of a trace of HNO₃; Me₂SO₄ gives the hexa-Me deriv., which exists in dimorphic forms, as reported for the deriv. from natural I. Hydrolysis with HI gives I, crystg. with 2 H₂O and m. 316° (decompn.); hexa-Ac deriv., m. 210°. Dyeing properties of I and II are reported. C. J. WEST

Action of calcium hydride on biphenylene oxide. WALTER FUCHS. Kaiser-

Wilhelm-Inst. f. Kohlen-Forschung in Mülheim-Ruhr. *Ber.* 61B, 2599-600(1928).—In a search for a general method of smoothly replacing heterocyclically bound O by H it was found that biphenylene oxide can be converted into Ph₂ by passing it over CaH₂ in H₂ at 450°. Each treatment lasted 10-15 mins. and by repeating it 3-6 times a 12-20% conversion of the oxide could be effected. No other reactions or decomps. were observed. The unchanged oxide is removed in petroleum ether with picric acid.
C. A. R.

Interaction of piperidine with nitro and halonitro derivatives of xanthone and diphenylene oxide. RAYMOND J. W. LE FÈVRE. Univ. College, London. *J. Chem. Soc.* 1928, 3249-52; cf. *C. A.* 21, 2673.—The expts. were carried out for the purpose of comparing the activities of the ethereal O atoms in xanthone and diphenylene oxide. Owing to the stability of these substances, their di-NO₂ derivs. were used. 3,6-di-nitrodiphenylene oxide was recovered unchanged after several hrs.' boiling with C₆H₁₁N(I) or PhNH₂(II). With I, α-dinitroxanthone gave (a) in the cold, a yellow substance which when isolated lost I, (b) when heated, a yellow powder which could not be crystd. β-Dinitroxanthone (III), when heated with I for 10 hrs. at 100°, gave 5,5'-dinitro-2'-piperidino-2-hydroxybenzophenone (IV), yellow, m. 155° (rapid heating). Heated at 200°, IV gave I and III. From IV was prepd. 5,5'-dinitro-2'-piperidino-2-acetoxybenzophenone, m. 253-5°. III with II in the cold gave a red addn. compd., but after 4 hrs.' boiling, III was recovered. Similar results were obtained with PhNHMe and o-MeC₆H₄NH₂. From 2,7-dibromoxanthone and fuming HNO₃ at 60° was obtained 2,7-dibromo-4,6-dinitroxanthone (V), m. 285-6°. V gave with I a gummy product which could not be sepd. Nitration of III gave 2,4,5,7-tetranitroxanthone (VI), did not m. 300°. VI with I in the cold gave a red color, but after heating 8 hrs. at 100°, VI was recovered.
LOUISE KELLEY

Chlorination of α-aminopyridine. A. E. CHICHIBABIN AND A. F. EGOROV. *J. Russ. Phys.-Chem. Soc.* 60, 683-90(1928).—The methods of chlorination of α-aminopyridine (I) (Sell, *C. A.* 3, 885 and Ger. pat. 400,191) give unsatisfactory yields of a mixt. of mono- and di-Cl derivs., depending upon the quantities of absorbed Cl. Best results were obtained by chlorinating in alc. Cl was conducted into an ice-cold soln. of 4.53 g. of I until 6.7 g. of Cl was absorbed, resulting in an 80% yield of chlorides, which on treatment with petroleum ether produced 68% of monochloroaminopyridine (II), m. 135-5.5°, and 0.9 g. of dichloroaminopyridine (III), m. 80-1°. When 3 g. of II is chlorinated under similar conditions until 2.5 g. of Cl is absorbed the yield of III is 75%. α-Nitroamino-β-chloropyridine is obtained when 3.38 g. of II in concd. H₂SO₄ is treated with 2 cc. HNO₃; the yield is 4.08 g., m. 159-160° (decomp.). The nitroaminochloropyridine is isomerized to aminonitrochloropyridine when 1.08 g. of the former in 20 cc. of concd. H₂SO₄ is heated for 1 hr. at 55°, poured on ice and made alk. with Na₂CO₃ (yield 2.63 g., m. 195-6°). A yield of 83% of di-chloro-α-hydroxypyridine, m. 163° is obtained by the action of KNO₃ upon a soln. of II in 20% H₂SO₄. Under somewhat similar conditions III produces dichlorohydroxypyridine, m. 177-8°, identical with the product obtained by Kenigsom (*Ber.* 17, 1832(1884); *C. A.* 3, 885). A yield of 3.5 g. of dichloropyridine, m. 59-60°, is obtained when 5 g. of II in 50 cc. HCl (d. 1.19) is treated with 5.5 g. of pulverized KNO₃, while 2.45 g. of III in 25 cc. of HCl (d. 1.19) treated with 2.1 g. of KNO₃ give 1.2 g. of trichloropyridine, m. 49-50°, which is identical with the product described in *Ber.* 17, 1837(1884).
CHAS. BLANC

Benzoylpiperidine. C. S. MARVEL AND W. A. LAZIER. *Org. Syntheses* 9, 169 (1929).—Detailed directions are given for the reduction of C₆H₅N with EtOH and Na, the residue, with NaOH and BzCl gives 77-81% of benzoylpiperidine, b₇₀ 190-4°, b₇₇ 191-4°, b₁₁₀ 240-4°. Direct benzoylation of piperidine gives 87-91% of the Bz deriv.
C. J. WEST

Preparation of quinaldiny chloride and ethyl quinaldinyacetate. DALZIEL L. HAMMICK AND WM. P. DICKINSON. Dyson Perrins Lab., Oxford. *J. Chem. Soc.* 1929, 214-5.—Quinaldinic acid and SO₂Cl₂ (even the purest SO₂Cl₂) give only the chloride, m. 175-6° (cf. Meyer, *Monatsh.* 23, 1199(1904); *Ber.* 38, 2488(1905)). However, the low melting chloride (97°; cf. Besthorn and Ibele, *Ber.* 38, 2127(1905)) is obtained from the acid and PCl₅ in ligroin. The low melting chloride and AcCH₃NaCO₂Et in C₆H₆ give 30% of Et quinaldinyacetate, m. 61°; Cu deriv., m. 178° (decomp.). Attempts to prep. the acetate from this deriv. failed; dry NH₃ in Et₂O gives quant. quinaldinamide; cold NH₃ and NH₄Cl have no effect; at 60° the amide is obtained.
C. J. WEST

Preparation of 1,3-benzodioxin. FREDERICK D. CHATTAWAY AND FERNANDO CALVERT. *Anales soc. españ. fis. quim.* 26, 417-22(1928).—1,3-Benzodioxin, the parent

substance of the condensation products of HCHO , CCl_3CHO , CHCl_2CHO and butyl-chloral with *p*-substituted phenols, has been isolated. Direct condensation of HCHO and phenol is impossible, but 6-nitro-1,3-benzodioxin on reduction gives 6-aminobenzodioxin, which by diazotization and reduction of the diazonium salt yields free 1,3-benzodioxin, colorless liquid, b_{765} 211–2°, with a peculiar odor.

E. M. SYMMES

N-Substituted derivatives of piperazine and ethylenediamine. I. Preparation of N-monosubstituted derivatives. TOM SIDNEY MOORE, MARY BOYLE AND VERA M. THORN. Royal Holloway College. *J. Chem. Soc.* 1929, 39–51.—To a concd. soln. of piperazine contg. some bromophenol blue, 2 *N* HCl was added until the neutral tint of the indicator appeared. Small quantities of ClCO_2Et and 2 *N* NaOH were run in at intervals, with vigorous stirring, and the process continued until a test showed that no piperazine remained (until the product of benzoylation of a few drops of the soln. is completely sol. in Et_2O); NaOH is then added and the dicarboethoxy deriv. extd. with Et_2O ; the soln. is then satd. with K_2CO_3 and extd. with Et_2O ; 38.8 g. of piperazine.6 H_2O gives 22.2 g. *Et* piperazine-1-carboxylate (*N*-carboethoxypiperazine) (I), b_{112} 116–7°, b_{170} 237°; CO_2 passed through I in Et_2O gives an addn. compd., which deliquesces in air and loses CO_2 in a desiccator; CS_2 forms an addn. compd., pale yellow, sublimes 130–40°, m. 148° (decompn.). BzCl gives the 4-*Bz* deriv., m. 82°. *N*-Benzoylpiperazine, m. 64°. The 4-*p*-toluenesulfonyl deriv. of I, m. 121°, and with 10% EtOH-KOH for 2 hrs. gives *N*-*p*-toluenesulfonylpiperazine, m. 110°; the CO_2 addn. compd., m. 107° (decompn.); the CS_2 addn. compd., pale yellow, m. 171°. *p*- $\text{MeC}_6\text{H}_4\text{SO}_3\text{Et}$ and I give the 4-*Et* deriv., b_{28} 136°; with concd. HCl this yields the HCl salt, deliquescent, of *N*-ethylpiperazine, b_{155} 8° (chloroplatinate; chloroaurate; CS_2 addn. compd., yellow, sublimes above 160°). Heating I with excess of $\text{ClCH}_2\text{CH}_2\text{OH}$ gives 70% of the 4- β -hydroxyethyl deriv., b_{17} 184°; concd. HCl gives *N*- β -hydroxyethylpiperazine-di-HCl, which forms a normal chloroplatinate and chloroaurate. I and $\text{ClCH}_2\text{CO}_2\text{Et}$ with Na_2CO_3 give *Et* 4-carboethoxypiperazinoacetate, b_{13} 183°; hydrolysis gives the HCl salt, orthorhombic crystals (for which crystallographic data are given), of piperazinoacetic acid, crystg. with 1 mol. H_2O , m. 279° (decompn.) if rapidly heated. Piperazino- β -propionic acid, m. 215°; HCl salt, deliquescent; *Et* 4-carboethoxypiperazino- β -propionate, b_{22} 198°; the γ -butyrate b_{21} 207°; piperazino- γ -butyric acid, m. 235°; chloroplatinate. Carboethoxyethylenediamine, b_{10} 135°; CO_2 gives an addn. compd., m. 102–3°; the CS_2 compd. differs from that of I but has not been obtained pure. The *N*-*Bz* deriv., m. 130°; the *N*-toluenesulfonyl deriv., m. 66°, and with 10% EtOH-KOH gives *N*-toluenesulfonylethylenediamine, m. 121°. *Et* *N*'-carboethoxyethylenediamino-*N*-acetate, could not be distd. and on hydrolysis gives the HCl salt of $\text{H}_2\text{NC}_4\text{H}_8\text{NHCH}_2\text{CO}_2\text{H}$, contg. 2HCl and 2 H_2O ; β -aminoethylglycine, very hygroscopic, m. 144°.

C. J. WEST

3-Chlorotropane and the non-existence of the bellatropine of Hesse. MAX POLONOVSKI AND MICHEL POLONOVSKI. *Compt. rend.* 188, 179–81 (1929).—Belladonine prepd. by polymerizing apotropine in acid or alkali gave a chloroplatinate m. 252° instead of 229° as given by Hesse. Its chloroaurate is amorphous, turns brown and softens at 150° and m. about 168° instead of 120°. H_2SO_4 hydrolyzes belladonine completely, giving tropine, from which the dehydrating action of H_2SO_4 produces a small amt. of tropidine. With HCl in a closed tube belladonine is sapond. not to bellatropine as given by Hesse but to 3-chlorotropane, which gives a HCl salt, m. 234°, a chloroplatinate, m. 227–8°, a chloroaurate, m. 215°, a picrate, m. 216–7°, a methiodide, m. 306°. Reduction of the latter with Zn and H_2SO_4 gives tropine-MeI. Oxidation of 3-chlorotropane with H_2O_2 gave the aminoxide, $\text{C}_8\text{H}_{11}\text{O}_2\text{NCl}$, whose HCl salt, m. 210°, and picrate, m. 175°, were prepd. HCl at 140° acting on apotropine, hyoscyamine and atropine produces 3-chlorotropane in each case. P. and P. recommend that the belladonine described by Hesse be stricken from the chem. literature.

R. C. ROBERTS

Synthesis of 3,10-dimethoxytetrahydroprotoberberine. SATYENDRA NATH CHAKRAVARTI AND WM. HENRY PERKIN, JR. Dyson Perrins Lab., Oxford. *J. Chem. Soc.* 1929, 196–201; cf. *C. A.* 22, 86.—*m*- $\text{MeOC}_6\text{H}_4\text{CO}_2\text{H}$, 40% HCHO and concd. HCl, heated 1 hr. on the steam bath, give 4-methoxyphthalide, m. 120°; oxidation with cold alk. KMnO_4 did not give the expected 4-methoxyphthalaldehydic acid but 4-methoxyphthalic acid, m. 168–70°. A mixt. of *m*- $\text{MeOC}_6\text{H}_4\text{CO}_2\text{Me}$, Cl_3CCHO , H_2O and H_2SO_4 , allowed to stand 5 days, gives nearly quant. 4-methoxytrichloromethylphthalide, m. 135°, hydrolyzed by NaOH to 4-methoxyphthalidecarboxylic acid, m. 170°; with SO_2Cl_2 this is converted into the chloride and this condensed with *m*- $\text{MeOC}_6\text{H}_4\text{CH}_2\text{CH}_2\text{NH}_2$ in C_6H_6 , giving 4-methoxyphthalidecarboxy- β -*m*-methoxyphenylethylamide, m. 129°; with POCl_3 on the steam bath for 6 hrs., followed by reduction with Zn and

AcOH, this yields 3,10-dimethoxyprotoberberine, m. 180°; concd. H₂SO₄ gives a faint violet soln., changed by a drop of concd. HNO₃ to a green and then a deep violet-blue, which finally changes to a fine orange-red. Electrolytic reduction gives 3,10-dimethoxytetrahydroprotoberberine, m. 139°.

C. J. WEST

Porphyrin syntheses. XXI. Synthesis of octaethylporphin. H. FISCHER AND R. BAUMLER. *Ann.* 468, 58-98(1929); cf. C. A. 23, 1134.—Since the investigation of octamethylporphin, the only sym. substituted porphin thus far prepd., is difficult because of the poor yield and its slight soly., it seemed desirable to prep. the Et deriv. 2-Methyl-4-ethyl-5-carbethoxypyrrole, AcCl, AlCl₃ and CS₂ give the 3-Ac deriv., identical with the pyrrole derived from EtCOCH₂CO₂Et and Ac₂CH₃. Sapon. with NaOH in EtOH gives quant. 2-methyl-3-acetyl-4-ethylpyrrole-5-carboxylic acid, m. 208°, which loses CO₂ on heating and gives 2-methyl-3-acetyl-4-ethylpyrrole (I), m. 129°; with Br in AcOH this yields the 5-Br deriv., m. 149°, which, warmed with excess Br, gives 2-methyl-3-bromo-4-ethyl-5-bromopyrrole, m. 161°. Bromination of I with 4 mols. Br in AcOH gives a perbromide of the methene-HBr (II), red prisms with a bluish violet luster, which does not m. 260°; the free base could not be obtained in condition for analysis; attempts to prep. the porphyrin from the HBr salt failed as did the attempted prepn. of the Cu salt. Oxidation gave a small amt of bromoethylmaleinimide 2,4-Dimethyl-3-carbethoxypyrrole and Br in Et₂O give 88% of the 5-Br deriv., m. 96° (decompn.); with Br in AcOH this yields 5-bromo-4-methyl-3-carbethoxypyrrole-5'-methyl-4'-carbethoxy-3'-methylpyrrolenylmethene, m. 153°; the HBr salt does not m. 260°. I and 40% HCHO give bis[2-methyl-4-ethyl-3-acetylpyrrol]methane, m. 259°, excess Br in hot AcOH gives the brick-red compd. (III), which has no m. p. 2-Bromomethyl-3-acetyl-4-ethyl-5-carbethoxypyrrole, m. 129° (analyzed as the 2-hydroxymethyl deriv., m. 101°, since the Br compd. could not be crystd.), heated with H₂O contg. a little HCHO, gives bis[2-carbethoxy-3-ethyl-4-acetylpyrrol]methane, m. 115°.

2-Bromomethyl-3-bromo-4-ethyl-5-carbethoxypyrrole, prepd. with an excess of Br in CCl₄, m. 170° (80% yield). 2-Methyl-3-bromo-4-ethyl-5-carbethoxypyrrole, m. 124°; excess Br gives the above di-Br compd. (EtCO)₂CH₂ transformed into the isomitoso form and treated with Ac₂CH₃ and finally with Zn dust, gives 75% of 2-methyl-3-acetyl-4-ethyl-5-propionylpyrrole, m. 137°; heating with dil. H₂SO₄ at 65-70° splits off the α-EtCO group, giving I; if the reaction is carried out above 70°, there results 2-methyl-4-ethylpyrrole. When I or its 5 CO₂Et deriv. is heated with EtONa and N₂H₄·H₂O 12 hrs. at 100-70°, there is formed 2-methyl-3,4-diethylpyrrole (IV), b.p. 104-5°, b. 202-3°, d₄ 0.90996, n_D²⁰ 1.49879; picrate, m. 101°. Its physiol. action is discussed. With HCN and HCl in Et₂O there results 2-methyl-3,4-diethyl-5-formylpyrrole, m. 74°. Oxidation of I with fuming HNO₃ gives diethylmaleinimide, m. 68°, which was also synthesized; the crystallographic properties are given. The monoxime, m. 197°. IV and excess HCO₂H give 5,5'-dimethyl-3,4,3',4'-tetraethylpyrrolenylmethene (V) yellow-red, m. 92°, isolated from the reaction product as the perchlorate, red with bluish violet surface luster, m. 173°; HBr salt, m. 202°; Cu complex, greenish blue prisms, m. 176°. Heating with 2 mols. Br in AcOH at 100° for 1.5 hrs. gives the 5,5'-bromomethyl deriv. of V, red prisms, which do not melt. IV (1 g.) in 5 cc. AcOH, treated in the daylight with 7.5 cc. of a Br soln. (50 g. Br in 100 cc. AcOH), gives 54-55% of the perbromide, red with a bluish violet surface luster, m. 132°, of 5-bromo-3,4-diethylpyrrol-5'-methyl-3',4'-diethylpyrrolenylmethene, brownish red, m. 97°; HBr salt, red with green surface luster, m. 194°. The perbromide with HBr·AcOH or (CH₃CO₂H)₂ gives octaethylporphin (VI), blue-violet, m. 318° (Maquenne block by slow heating) (55% yield); reduction gives octaethylporphyrinogen, m. 184°. Spectroscopic data are given for VI in various solvents. The hemin of VI, C₂₈H₄₄N₄FeCl, bluish violet, sinters 280-300° (spectrographic data); the bromohemin forms blue needles; the iodohemin is blue-violet. The phyllin of VI, C₂₈H₄₄N₄Mg, is blue-violet and does not m. 400°, the Cu complex of VI is red and m. 310°. The behavior of VI on oxidation with fuming HNO₃ and with H₂O₂ is reported. VI and excess of Br in AcOH give the compd. C₂₈H₄₄N₄Br₈ light bluish violet with no m. p. IV and EtMgBr, followed by ClCO₂Et, give 55% of 2-methyl-3,4-diethyl-5-carbethoxypyrrole, m. 75°; Br gives an unstable 2-bromomethyl-3-acetyl-4-ethyl-5-carbethoxypyrrole, m. 105°; an excess of MeOH contg. a little HCHO gives bis[2-carbethoxy-3,4-diethylpyrrol]methane, m. 180°. 5,5'-Dibromo-3,4,3',4'-tetraethylpyrrolenylmethene-HBr, red, decompa. 206° (block). VI in CHCl₃ and AcOH, shaken with PbO₂

gives *octaethylxanthoporphinogen*, citron-yellow, crystg. with 2.5 H₂O, of which 2 mols. are retained at 100°, m. 274° (decompn.). 2,4-Dimethyl-3-isovaleroyl-5-carbethoxy-pyrrole, m. 99° (50–5% yield). XXII. Syntheses of hematoporphyrin, protoporphyrin and hemin. H. FISCHER AND K. ZEILE. *Ibid* 98–116.—Deuterohemin with Ac₂O and AlCl₃ or SnCl₄ gives *di-Me 1,3,5,8-tetramethyl-2,4-diactylporphin-6,7-dipropionate* (I), m. 236° (cor.); spectroscopic data; sapon. with concd. HCl gives *diactyldeuteroporphyrin* (II), whose spectroscopic behavior in various solvents is given. The Fe complex of I, m. 229° (cor.); spectroscopic behavior; the Cu salt, m. 230° (cor.). Heating II with KOH in abs. EtOH gives hematoporphyrin, isolated as the HCl salt (III); heating in a high vacuum 2 hrs. at 105° gives protoporphyrin, which yields the di-Me ester with MeOH-HCl, m. 228°. Reduction of III gives mesoporphyrin. For a discussion of these syntheses the reader is referred to the original paper. C. J. W.

Cholesterol. E. MONTIGNIE. *Bull. soc. chim* 43, 1103 5(1928); cf. C. A. 22, 4534.—Oxidation of cholesterol with HgO in glacial AcOH gave α -hydroxycholesterol. Heating cholesterol with Ac₂O in a closed tube at 150° for 20 hrs. gave the acetate of cholesterol. Heating cholesterol and camphoric acid at 190–200° for 15 mins. gave the neutral camphorate C₂₇H₄₄(CO₂C₁₀H₁₆)₂. The action of HClO₄ on cholesterol is a dehydrating one, giving α - and β -cholesterylene. R. C. ROBERTS

The odoriferous products from musk and the many-membered rings. L. RUZICKA. Univ. of Utrecht. *Bull. soc. chim* 43, 1145–73(1928).—An address reviewing the work done on musk and civet in detg. their compn. A bibliography is included.

Organic bases. I. G. FARBENIND. A.-G. Fr. 646,711, Jan. 4, 1928. Org. bases are obtained by circulating at a raised temp., and with or without pressure, on catalysts composed of inorg. salts capable of forming ammoniates, vapors composed of C₂H₂ and NH₃ or primary or secondary alkyl-, aralkyl- or arylamines. In examples C₂H₂ and NH₃ are caused to circulate at 200° over pumice impregnated with anhyd. ZnCl₂. The product obtained contains NHEt₃, NEt₃ and methylpyridine and their hydrogenation products. If FeCl₃ is used as well as ZnCl₂ at 220–300°, the product contains homologs of pyridine. If PhNH₂ and C₂H₂ are circulated at 300–320° over ZnCl₂, the product contains quinaldine. If *o*-toluidine is used instead of PhNH₂, 8-methylquinaldine is obtained. If *m*-xylydine and C₂H₂ are circulated over CoCl₂, dimethylquinaldine is obtained. PhNHEt and C₂H₂ over ZnCl₂ give quinaldine, *N*-ethylindole, and *N*-ethylidihydroquinaldine, C₂H₂ and *o*-chloroaniline on ZnCl₂ give 8-chloroquinaldine.

Catalytic oxidation of organic compounds. A. O. JÄGER (to Selden Co.). Brit. 296,071, Aug. 26, 1927. Oxidations, especially those in the vapor phase, are effected by use of a catalyst contg. a multicomponent zeolite formed by the reaction of at least one sol. silicate, at least one metallate and at least one metal salt, the basic radical of which enters the non-exchangeable nucleus of the zeolite. The catalytic element may be contained in or combined with the zeolite or may be contained in a diluent with which the zeolite may be mixed. The silicate component consists of an alkali

metal silicate which may contain alkali salts of acids of the elements, B, P, S, N, Sn, Te, Se, As, or Sb. The metallate component consists of alkali metal compds. of the elements Al, Cr, Zn, V, Be, Sn, Pd, Os, Pt, Ti, Zr, Pb, W, B, Mo, U, Ta, Cu, Ni, Fe, Co, Ag, Cd, Mn, Bi, Th, or Ce. The metal may be present in complex ions formed with NH_3 , HCN, HCNS, oxalic, formic, tartaric or citric acids, glycerol or sugars. The metal salt component consists of a sol. salt of Cu, Ag, Au, Be, Zn, Cd, Al, rare earths, Ti, Zr, Sn, Pb, Th, Cr, U, V, Mn, Fe, Ni, or Co. The alkali metal in the zeolite may be replaced by base exchange by the cations, NH_4 , Cu, Ag, Au, Be, Mg, Ca, Zn, Sr, Cd, Ba, Al, Ti, Ti, Zr, Sn, Th, V, Cr, U, Mn, Fe, Co, Ni, Pd, or Pt, either as simple or complex ions. The zeolites may be treated to form salt-like compds. by treatment with acids or salts of acids of V, W, U, Cr, Mo, Mn, Se, Te, As, P, S, Cl, Br, F, N, or B, or with polyacids or peracids or their salts, or with compds. contg. complex anions such as ferro-, ferri-, sulfo-, or metal-CN, NH_3 complexes, etc. The catalysts are suitable for use in the oxidation of C_6H_6 , toluene, phenol, naphthalene, anthracene, fluorene, eugenol, isoeugenol, MeOH, or EtOH, etc., to produce their desired oxidation products or for selective oxidations in purification treatments. Cf. C. A. 23, 1135.

Catalytic production of alcohols, aldehydes, ketones, acids, ethers, esters, etc. SOC. CHIMIQUE DE LA GRANDE-PAROISSE AZOTE ET PRODUITS CHIMIQUES. Brit. 296,049, Aug. 24, 1927. Various O-contg. org. compds. are obtained by the reaction of CO (or a suitable gas contg. CO) on H_2O in the presence of a mixed catalyst contg. at least 1 element of the series K, Na, Mg, V, Cr, Mo, Mn, Fe, Co, Ni, Cu, Ag, Zn, Cd, Hg, Pb, As, Sb, Bi, in assocn. with at least 1 element of the series Be, Mg, Al, Ce, Si, Ti, Zr, Th, U, Li, Ca, Sr, Ba and W. Temps. up to 550° and pressures up to 600 atm may be used and the walls of the reaction vessels may be made of chrome, silicon or manganese steels or of Cu or Ag. Examples are given of the production of: (1) alcs. with a catalyst formed of Mn carbonate, MgO and Al_2O_3 ; (2) formic acid with a catalyst of Th oxide and K_2CO_3 ; (3) ethers with a catalyst of Cu, Th and Bi compds. pptd. on pumice; (4) alcs. with a catalyst formed of Mn oxide, MgO and Al_2O_3 ; (5) alcs. and other org. compds. with use of a catalyst comprising a ppt. obtained by treating a soln. formed from HCl, antimonious oxide and Th nitrate with $(\text{NH}_4)_2\text{CO}_3$; (6) alcs. with a catalyst formed by treating a soln. of Pb nitrate and Sr nitrate with $(\text{NH}_4)_2\text{CO}_3$, and (7) production of lower aliphatic alcs. and acids with a catalyst contg. Th and Co and prepd. similarly to the catalyst of "6."

Aldehydes, alcohols, etc. J. C. WALKER (to Empire Gas & Fuel Co.). Brit. 295,356, Aug. 10, 1927. Gases such as natural gas or gases from the thermal decomposition of coal, petroleum or shale, which may contain olefins, are mixed with air, O_2 , or one or C oxides in sufficient quantity to form aldehydes and alcs. with some of the hydrocarbons such as C_2H_4 and higher hydrocarbons while leaving the CH_4 unchanged and are treated catalytically to obtain a gaseous product (after removal of the oxidation products) of a uniform calorific power. The catalyst may be suitable for dehydration, dehydrogenation and oxidation reactions such as Pt, Pd, Au, Ag, Cu, Cr, Mn, Fe, and Ni and compds. such as oxides of Cu, Mn, Fe, Ni, V, Cr, Mo, Ce and other metals having higher and lower oxides and alloys or mixts. of such metals which may be used on carriers such as pumice, asbestos fiber or alundum. An app. and various details of procedure are described. Cf. C. A. 23, 848.

Organic oxygen compounds. I. G. FARBENIND. A.-G. Fr. 646,087, Dec. 22, 1927. Benzene hydrocarbons contg. a side chain with at least 2 atoms of C are oxidized in the liquid state by means of O at a high temp. in the presence of catalysts derived from heavy metals. It is found that the O has a special affinity for the C atom in the α -position and oxidation occurs there first. In examples, a mixt. of acetophenone and methylphenylcarbinol is obtained by passing air through PhEt at 120° in the presence of FeCl_3 or heated $\text{Cu}(\text{NO}_3)_2$ or oxide of Fe, etc. Isopropylbenzene with oxide of Cu gives acetophenone and dimethylphenylcarbinol.

Organo-arsenic compounds. G. NEWBERRY and MAY & BAKER, LTD. Brit. 295,744, March 23, 1927. *N*-Acetylhydroxy derivs. of arylarsonic acids are prepd. from *o*-aminohydroxyarylarsonic acids by first protecting the amino group (as by introducing an acyl group such as acetyl or benzoyl) and then treating the acid with an α -haloacetic acid or a readily hydrolyzable deriv. such as the amide or an ester. By hydrolysis of the product the protecting group is eliminated and the *o*-substituted residues condense to form the corresponding isoxazines compd. Examples are given of the production of 3-hydroxy-1,4-benzisoxazine-6-arsonic acid and 8-amino-3-hydroxy-1,4-benzisoxazine-6-arsonic acid; acetylation of the latter produces the 8-acetylaminoo compd. which is described in Brit. 278,444 (C. A. 22, 2571).

Organic antimony compounds. AUGUST ALBERT. Ger. 469,327, Jan. 13, 1923.

Mixed aliphatic-aromatic Sb compds. contg. carbonyl groups at noncyclic bonds, are treated with hydrazine or its derivs., especially semicarbazide, or with other reactive amino compds. Thus, an aq. soln. of *p*-acetophenonestibonic acid contg. NaOH is added to semicarbazide-HCl and warmed in a water bath. The clear filtrate is acidified with HCl to ppt. the colorless hydrazone product which is purified by redissolving in Na₂CO₃ and repptg. with acid. Its m. p. is 350°. An alc. soln. of 1-hydroxy-2-acetophenone-4-stibonic acid may be treated similarly. Other examples are given.

Benzyl compounds of antimony. I. G. FARBENIND. A.-G. (Max Hardtmann, inventor). Ger. 466,364, June 30, 1925. Benzylmagnesium halide is allowed to react with Sb trihalide. Thus, tribenzyl antimony is obtained by the reaction of benzylmagnesium chloride on a soln. of SbCl₃ in ether.

Aromatic amines. I. G. FARBENIND. A.-G. Brit. 295,824, Aug. 4, 1927. See Fr. 639,557 (C. A. 23, 605).

Amino alcohols. SOC. ANON. POUR L'INDUSTRIE CHIMIQUE À BALÉ. Brit. 296,006, Aug. 22, 1927. Hydrogenation of aryl aminoalkyl ketones to the corresponding carbinols is effected in alk. soln. (suitably by use of Ni or metals of the Pt group as catalysts); O should be excluded from the app. used. An example is given of the production of methylaminomethyl-3,4-dihydroxyphenylcarbinol from ω -methylaminoacetopyrocatechol.

Hydroxydiaryl ketones. I. G. FARBENIND. A.-G. Fr. 646,402, Dec. 27, 1927. Hydroxydiaryl ketones are prepd. by treating hydroxyarylcboxylic acid halides with aromatic hydrocarbons or their ring-substituted derivs., in the presence of acid condensing agents. In examples, 2,3-hydroxynaphthoyl chloride is dissolved in C₆H₆, AlCl₃ or ZnCl₂ is added and the mixt. heated to 70–75°, and 2,3-hydroxynaphthophenone, m. 161–162°, is isolated in known manner. If PhMe is used instead of C₆H₆, 2,3-hydroxynaphthyl tolyl ketone, m. 152–153°, is obtained. If anisole is used instead of C₆H₆, 2,3-hydroxynaphthyl anisyl ketone, m. 134–134.5° is obtained. 2-Hydroxy-6-naphthoic acid is dissolved in C₆H₆ with SOCl₂, and excess of C₆H₆ and SOCl₂ are distd. off. The remaining 2,6-hydroxynaphthoyl chloride is dissolved in CS₂ and heated with anisole and AlCl₃, producing 2,6-hydroxynaphthyl anisyl ketone, m., 196–197° (uncorrected). *m*-Xylenolcarboxylic acid is converted into its chloride with PCl₅ and heated with anisole and AlCl₃, to give 4-hydroxy-5-anisoyl-1,3-xylene, m. 105–106° (uncorrected). C₁₀H₈ and its derivs. also may be used.

Esters. HOLZVERKOHLE-INDUSTRIE A.-G. Brit. 295,275, Aug. 8, 1927. Esterification of alcs. with aliphatic acids is effected (preferably under 2–8 atm. pressure and at moderate temps. corresponding to the pressure used) in the presence of limited quantities of catalysts which maintain the reaction mixt. of p_H 1.5–3.0 and the ester formed may be continuously removed by distn. As catalysts, there may be used inorg. acids or strongly hydrolyzed salts such as sulfates of heavy metals, Al, Mg and NH₄, acid phosphates of alkali and alk. earth metals, borates, salts of complex acids and of org. sulfonic acids, and salt mixts. giving a buffer action. The preliminary stage of the esterification may be carried out before addn. of the catalyst if desired. An example is given of the continuous production of MeOAc from MeOH and HOAc in a column app. with use of H₂SO₄ and NaHSO₄ as catalysts.

Esters of diiodobehenic acid. I. G. FARBENIND. A. G. (August Wingler, inventor). Ger. 468,021, May 13, 1925. Esters liquid at ordinary temps. are prepd. by esterification or reesterification. The acid may be iodized after the esterification. Thus, diiodobehenic acid is treated with isobutyl alcohol contg. 4% concd. H₂SO₄ at 100°. Or, behenic acid is heated to 100° with isobutyl alcohol, and 4% concd. H₂SO₄ added. The ester is then dissolved in CS₂, dried and I added. The mixt. is exposed to bright light at 40° for some days. Alternatively, ethyl diiodobehenate, m. 37°, may be heated to 100° with isoamyl alcohol and 3% HCl added. Cf. C. A. 23, 241.

Esters of polycarboxylic acids. ROBERT H. VAN SCHAAECK, JR., and ROBERT CALVERT (to Van Schaack Bros. Chemical Works). U. S. 1,706,639, March 26. Diethoxyethyl phthalate, b. 200–2°, a colorless liquid which may be used as a solvent for nitrocellulose and a plasticizer in lacquers is made by digestion (suitably in a fractionating column) of phthalic anhydride and glycol monoethyl ether in the presence of a small quantity of H₂SO₄. Similarly, there may be prepd. diethoxy-*sec*-butyl phthalate, ethoxyethylbutyl phthalate and similar methyl, iso-Pr, iso-Am, Am, hexyl or benzyl derivs. Several formulas of lacquer compns. are given, including one of these esters, as are also details of making the diethoxyethyl phthalate and butylethoxyethyl phthalate. Esters of citric, tartaric, succinic, phenylmalonic or trimelic acids may be similarly prepd.

Bornyl and isobornyl esters. GAZA AUSTRIERWERN. Ger. 468,320, Sept. 26, 1925.

Nopinene is heated with org. acids in double mol. quantities in terpene or α -pinene to moderate temps. not exceeding 150° . Thus, nopinene and benzoic acid are dissolved in xylene and heated to 140 – 150° . After cooling, the mixed acid is washed out and the residue driven over a satd. soln. of Na_2CO_3 by steam. The residual bornyl ester is sapond. Oil of turpentine can be used instead of nopinene.

Aminodiaryl ethers. I. G. FARBERIND. A.-G. Fr. 645,963, Dec. 20, 1927. *o*-Aminodiaryl ethers are prepd. by reducing *o*-nitrodiaryl ethers which are obtained by reacting an alkali salt of a hydroxy aromatic compd., with or without a diluent on *o*-dinitrobenzene compds. In examples, *o*-dinitrobenzene and PhOK are heated to give *o*-nitrodiphenyl ether which can be reduced to *o*-aminodiphenyl ether, m. 41° . 3,4-Dinitro-1-chlorobenzene and PhOK are heated, giving 5-chloro-2-nitrodiphenyl ether, m. 85° (uncorrected), which is reduced to the amino compd., m. 40 – 1° (uncorrected). Na 2,5-dichlorophenolate is heated in alc. soln. with 3,4-dinitro-1-chlorobenzene, giving 5,2',5'-trichloro-2-nitrodiphenyl ether, m. 97 – 98° , which is reduced to the amino compd. m. 74 – 75° . In the same manner, 5-chloro-2-nitrophenyl β -naphthyl ether, m. 109 – 110° , and the corresponding amino compd., m. 108 – 109° , may be obtained. Among other new compds. which may be obtained are 5,4'-dichloro-2-nitrodiphenyl ether, m. 80 – 81° (uncorrected), and 5,4-dichloroaminodiphenyl ether, m. 76 – 77° .

Aminonaphthol ethers. I. G. FARBERIND. A.-G. Fr. 646,576, Dec. 30, 1927. Aminonaphthol ethers are obtained by treating hydroxynaphthalenecarboxamides with alkylating or aralkylating agents and submitting the naphtholcarboxamide ethers to a Hofmann decompn. In examples, a soln. of 2,3'-hydroxynaphthamide in NaOH soln. is mixed with Me_2SO , and boiled, giving 2,3-methoxynaphthamide, m. 170° (uncorrected). The latter is treated in MeOH with NaOCl and concd. NaOH to obtain 2,3-aminonaphthol Me ether, m. 107° (uncorrected). 1,2-Hydroxynaphthamide is ethylated with the Et ether of *p*-toluenesulfonic acid to give 1,2-ethoxynaphthamide, m. 154° (uncorrected), which with the Hofmann decompn. gives 2,1-aminonaphthol ether, m. 48 – 49° (uncorrected). Similarly, 2,6-hydroxynaphthamide, m. 206° (uncorrected), (from 2,6-hydroxynaphthoyl chloride and NH_3) gives with benzyl chloride 2,6-benzoxynaphthamide, m. 198° (uncorrected), and the latter after the Hofmann decompn. gives 2,6-aminonaphthol benzyl ether, m. 198° (uncorrected). In the same way 2,6-methoxynaphthamide, m. 224° (uncorrected), gives 2,6-aminonaphthol Me ether, m. 156 – 157° (uncorrected).

Alkylated naphthalenes. I. G. FARBERIND. A.-G. Brit. 295,990, Aug. 22, 1927. In a modification of the processes described in Brit. 285,601 (C. A. 22, 433) and Brit. 273,665 (C. A. 22, 1983) for the production of alkylated naphthalene derivs., propylene or its higher homologs are caused to react with C_{10}H_8 or a deriv. in the presence of a Friedel-Crafts catalyst such as AlCl_3 (suitably under reduced pressure).

Aromatic mercaptans. ERWIN HOFFA and PAUL JÖRG (to Grasselli Desulfur Corp.). U. S. 1,706,489, March 26. Mercaptans of the general formula R SH (in which R means a nonsubstituted or substituted benzene or naphthalene residue) are obtained in good yields from diazoaryls contg. no solubilizing group by reaction with sulfides such as those of Na or Ca contg. more S than that present in Na_2S or CaS . The reaction is preferably effected at temps. above 60° , since at lower temps. explosive diazo sulfides may be formed. Alk. substances such as a carbonate, bicarbonate or alk. silicate, or a catalyst such as Cu or a Cu salt may promote the reaction. Several examples are given.

Polymerizing ethylene to form liquid hydrocarbons. C. EPNER. Brit. 295,705, Aug. 18, 1927. Polymerization is effected by the action of dark or silent elec. discharges at ordinary or raised temps., with or without use of catalysts. The product contains both satd. and unsatd. hydrocarbons from which fractions suitable for motor fuel and lubricating oil can be obtained. The residual gas contains H and can be used to saturate the unsatd. hydrocarbons in the presence of catalysts as a part of a continuous process.

Acetonitrile and other organic nitrogen bases. I. G. FARBERIND. A. G. Brit. 295,276, Aug. 8, 1927. Reaction of C_2H_2 with NH_3 is effected by heating and use of a catalyst contg. a plurality of compds. such as oxides which are not reducible under the conditions of the reaction, e. g., a mixt. of active alumina gel with silica gel or a mixt. of ZnO with irreducible oxides of the third or fourth periodic group. According to one example of the process, a mixt. of C_2H_2 and NH_3 is passed at 350° through a tube contg. a catalyst prepd. by suspending oxides of Th and Zr in water and drying and breaking up the paste. The product includes acetonitrile and pyridine bases. Acetonitrile is also formed by passing a mixt. of C_2H_2 and NH_3 at 450° through a series of tubes contg. a catalyst prepd. by impregnating active silica with an aq. soln. of Zn and Th nitrates, drying and calcining.

Nitriles of benzanthrone. KALLE & Co. A.-G. (Maximilian P. Schmidt and Wilhelm Neugebauer, inventors). Ger. 467,118, Nov. 18, 1924. These nitriles are prep'd. by acting on the halogenated benzanthrone with CuCN. Thus, monobromobenzanthrone is mixed with CuCN and heated to 200–210°. The mass is ground up and the nitrile extd. with hot PhNO₂. Also, dibromobenzanthrone, m. 257°, is heated to 160° with CuCN and pyridine, and the mixt. diluted with NH₄OH. The dinitrile is extd. with PhNO₂.

Benzanthrone. I. B. ANDERSON, R. F. THOMSON, J. THOMAS and SCOTTISH DYERS, LTD. Brit. 295,213, Feb. 2, 1927. Benzanthrone derivs. are prep'd. by treating 3-alkoxy(or hydroxy)-4,4'-diamino-1,1'-naphthylphenyl-2'-carboxylic acid with an alkali in aq. soln. The starting material may also be substituted in the 2, 5, 6, 7, 3', 5' or 6' positions by univalent groups such as alkyl, halogen or alkoxy. A mixt. of 6-Bz-1-diamino-Bz-2-methoxybenzanthrone and 6-aminobenzanthrone Bz-1-Bz-2-oxide is formed when 4,4'-diamino-3-methoxy-1,1'-naphthylphenyl-2'-carboxylic acid hydrochloride is dissolved in NaOH soln. and heated until evolution of methylamine ceases; similar treatment of 4,4'-diamino-3-hydroxy-1,1'-naphthylphenyl-2'-carboxylic acid gives 6-Bz-1-diamino-Bz-2-hydroxybenzanthrone in the cold and, on heating, a mixt. of thio- and 6-aminobenzanthrone Bz-1-Bz-2-oxide by loss of NH₃. 4,4'-Diamino-3-alkoxy(or hydroxy)-1,1'-naphthylphenyl-2'-carboxylic acid is made by coupling β -naphthol with diazotized *m*-aminobenzoic acid, reducing the azo compd. formed in acid soln., and if desired alkylating the product.

Aminoanthraquinones. I. G. FARBENIND. A.-G. Fr. 646,130, Dec. 23, 1927. Aminoanthraquinones and their derivs. are prep'd. by oxidizing the corresponding leuco-amino compds. in the presence of an agent liberating O and with catalysts. In examples, leuco-1,4-diaminoanthraquinone is heated to 140° in PhNO₂ with the addn. of S₂Cl₂. If an excess of S₂Cl₂ is used 1,4-diamino-2,3-dichloroanthraquinone is formed. Leuco-1,4-diamino-5,8-dihydroxyanthraquinone is oxidized in the same way with piperidine as a catalyst, and leuco-1,4-dibenzylidiaminoanthraquinone is oxidized in *o*-dichlorobenzene with benzoyl peroxide as catalyst. Other catalysts are Et₃N and HCl.

Halogen substituted 2-pyridone. MAX DOHRN and RALPH DIRKSEN (to Schering-Kahlbaum A.-G.). U. S. 1,706,775, March 26. 2-Pyridone is dissolved in a solvent such as CHCl₃ or dil. HCl and halogenated, *e. g.*, by Cl gas (to form a mixt. of 2-hydroxy-5-chloropyridine and 2-hydroxy-3,5-chloropyridine) or with ICl (to form 2-hydroxy-3,5-iodopyridine).

Hydrocarbon halogen derivatives. M. POLANYI and S. VON BOGDANDY. Brit. 296,021, Aug. 23, 1927. In forming halogen derivs. of org. compds. as described in Brit. 289,795 (C. A. 23, 847) the vapor of Cd or Zn is used as an "initiator" of the reaction.

Derivatives of dimethoxydibenzanthrone. MARCEL BADER, CHARLES SUNDER and DURAND & HUGUENIN SOC. ANON. Swiss 127,948, Mar. 14, 1927. Addn. to Swiss 102,540. Stable water-sol. derivs. in the form of acid esters of H₂SO₄ are prep'd. by converting the leuco compds. by the action of aminosulfonic acid. Thus, finely powd. aminosulfonic acid is stirred with pyridine and heated to 80°, when the leuco compd. of Bz-2,Bz'-2-dimethoxydibenzanthrone is added, and the mixt. further stirred and heated. After standing, water-free NaOH is added and the pyridine blown off by steam. The Na salt of the H₂SO₄ ester of leuco-dimethoxydibenzanthrone is obtained by evap. to dryness.

Anthraquinone derivatives (intermediates for making dyes or pharmaceutical products). I. G. FARBENIND. A.-G. Brit. 295,943, Aug. 18, 1927. Nitro compds. are formed by treating 1,2,3,4-tetrahydroanthraquinone or its homologs or substitution products with a nitrating agent. By use of a mixt. of HNO₃ and H₂SO₄, a nitro group enters the *ar*-nucleus and no dehydrogenation occurs. Examples are given of the production of *ar*- α -nitro-1,2,3,4-tetrahydroanthraquinone together with a smaller proportion of the corresponding *ar*- β -nitro compd. from 1,2,3,4-tetrahydroanthraquinone of the production of 1,2,3,4-tetrahydro-8-nitro-7-methylantraquinone from 1,2,3,4-tetrahydro-7-methylantraquinone, and of the production of 1,2,3,4-tetrahydro-8-acetylaminoanthraquinone (by reducing and acetylating the *ar*- α -nitro-1,2,3,4-tetrahydroanthraquinone) which may be nitrated to form 1,2,3,4-tetrahydro-8-acetylamino-5-nitroanthraquinone. H₂SO₄ alone has a dehydrogenating action on tetrahydroanthraquinones and Br converts them into unstable derivs. contg. Br in the hydrogenated nucleus, which easily lose HBr and form the corresponding anthraquinones.

Naphthalene derivatives. I. G. FARBENIND. A.-G. Brit. 296,010, Feb. 21, 1927. Cyanonaphthalenesulfonic acids with at least one sulfo group in *o*- or *p*-position to

the CN group are heated with alk. reagents to produce the corresponding compds. of one of the types: (1) $C_{10}X_2(OH)(CN)$, (2) $C_{10}X_2(OH)(CONH_2)$, (3) $C_{10}X_2(OY)(CONH_2)$ or (4) $C_{10}X_2(OY)(COOH)$ in which X is H or a univalent substituent, and Y is an alkyl or aralkyl group. Examples are given of the production of 2,1- and 1,4-cyanonaphthols, 1,2- and 1,4-hydroxynaphthoic acids, 7-sulfo-2,3-hydroxynaphthoic acid, 2,7-dihydroxy-3-naphthoic acid, 6- or 7-sulfo-1,4-hydroxynaphthoic acid, the amides of 2,1-, 1,2- and 1,4-methoxynaphthoic, 2,1- and 1,4-ethoxynaphthoic, 2,1- and 1,4-butoxynaphthoic, and 1,2-benzoyloxynaphthoic acid, and of 1,2- and 1,4-methoxynaphthoic, 1,4-ethoxynaphthoic and 1,4-butoxynaphthoic acids. *o*- and *p*-Cyanonaphthalenesulfonic acids and their nuclear substitution products are obtained from the corresponding aminonaphthalenesulfonic acids by Sandmeyer's reaction.

Naphthostyryl derivatives. I. G. FARHENIND. A.-G. (Heinz Scheyer, inventor) Ger. 471,268, Jan. 13, 1927. *N*-Chloronaphthostyryls are prepd. by treating naphthostyryl or its nuclear substitution products with hypochlorites. Examples are given describing the prepn. of *N*-chloronaphthostyryl, m. 132°, and *N*-chloro-5-ethoxynaphthostyryl, m. 117°.

Naphthostyryl derivatives. I. G. FARHENIND. A.-G. (Heinz Scheyer, inventor) Ger. 471,269, Jan. 13, 1927. Naphthostyryl derivs. substituted in the nucleus with 1 atom of Cl are prepd. from the *N*-chloronaphthostyryls prepd. according to Ger. 471,268 (above) by treating them with acid condensing agents or by heating them alone or in a high-boiling org. solvent. Examples are given describing the prepn. of 4-chloronaphthostyryl and 4-chloro-5-ethoxynaphthostyryl from the corresponding *N*-chloro derivs.

Piperidine derivative. MARCEL DE MONTMOLLIN. Swiss 127,779, May 9, 1927. A deriv. of piperidine substituted in the β - and γ -positions is prepd. by treating the dinitrile with reducing agents and closing the ring in the diamine thus obtained by dry distn. of the hydrochloride. Thus, 2-methyl-1,3-pentanedinitrile is dissolved in alc., Na added and the mixt. boiled with a reflux condenser. On distg. the alc. the residue contains 2-ethyl-3-methylpentamethylenediamine, which is extd. with ether. The diamine is then treated with HCl, forming crystals of the hydrochloride, which is heated to give β -ethyl- γ -methylpiperidine.

Alkali salts of nitrosamines. I. G. FARHENIND. A.-G. Fr. 646,359, Dec. 26, 1927. Alkali salts of nitrosamines of aromatic amines are prepd. by introducing the *syn*-diazotate prepd. at low temp. into a sufficiently concd. caustic alkali lye and carefully maintaining the temp. of the reaction mixt. equal to or higher than the temp. of transformation into the *anti*-diazotate. In examples, a concd. soln. of *m*-chlorobenzenediazonium chloride is introduced at a temp. not above 5° into a soln. of 33° Bé. KOH. Secondary products are filtered off and the soln. of *syn*-diazotate thus obtained is poured with stirring into strong KOH soln. the temp. being kept at about 105°. The K salt of the nitrosamine of *m*-chloroaniline is obtained. In the same way the K salt of the nitrosamine of 3,4-dichloro-, 2,4,5-trichloro- and 2,4,6-trichloroaniline, and the Na salt of the nitrosamine of 2-chloro-5-bromoaniline are prepd. The *syn*-diazotate prepd. at a low temp. from the diazo compd. of 5-chloro-2-toluidine and KOH soln., is introduced into concd. KOH soln. at 115°, whereby the K salt of the nitrosamine of 5-chloro-1,2-toluidine is obtained, contg. the group-NKNO in the 2 position. Similarly at a transformation temp. of 110° a K salt of the nitrosamine of 4-chloro-1,2-toluidine and at 120° of 2,6-dichloro-4-amino-1,3-xylene and 5,6-dichloro-2-toluidine are obtained. The alkali salts of the nitrosamines of 4-bromo-2-toluidine, of 5-chloro-2-bromo-1,4-toluidine, of 4-chloro-1,3-toluidine, of 4,5-dichloro-1,2-toluidine, of 2,5-dichloro-1,4-toluidine, of 2,3-dichloro-1,4-toluidine, of 6-chloro-1,2-toluidine, are also described. The Na salt of the nitrosamine of 4-chloro-1,2-anisidine and of 4-chloro-1,2-dianisidine are prepd. at a transformation temp. of 110°. The K salt of the nitrosamine of 4-chloro-1,3-anisidine is prepd. at 115-120°, and of 1-aminoanthraquinone at 120-125°.

Sulfo acids. I. G. FARHENIND. A.-G. (Gerhard Balle and Karl Daimler, inventors) Ger. 466,362, March 1, 1925. Sulfo acids suitable for emulsifiers are prepd. by treating aralkylized mononuclear aromatic hydrocarbons with alc. during or after the sulfonation. Thus, benzyltoluene is treated with butyl alcohol at 50°. The temp. is then raised to 90° and a mixt. of chlorosulfonic acid and fuming H_2SO_4 added. Benzyltoluene and isobutyl alcohol are also mentioned in examples.

Acetic acid. HERMANN SUDA. Ger. 469,942, June 18, 1926. (See Austrian 111,566 (C. A. 23, 1419).)

Concentrating acetic acid. I. G. FARHENIND. A.-G. Brit. 29,338, May 4, 1927. See Fr. 633,817 (C. A. 22, 3669).

H. SUDA. Brit. 295,641, Aug. 15, 1927. Extr.

of HOAc from its aq. solns. is effected in the liquid phase by esters of univalent or multivalent alcs. with monobasic or polybasic cyclic acids, having b. ps. above 150° (such as di-Et or di-Bu phthalate, di-Me or dihexyl phthalate, esters of the naphthene acids and high-b.-p. esters of benzoic acid) and the extd. HOAc is sep'd. from the solvent by distn. The extn. may be carried out countercurrentwise. Cf. C. A. 23, 1909.

2-Aminonaphthalene-3-carboxylic acid. I. G. FARBENIND. A.-G. Fr. 645,875, Dec. 17, 1927. See Brit. 282,450 (C. A. 22, 3669).

Salts of 1-methyl-4-isopropylbenzenesulfonic acid. CHEM. FAB. VON HEYDEN A.-G. (Curt Philipp, inventor). Ger. 466,360, Nov. 27, 1924. Salts of this acid and its substitution products are prepd. by the reaction of sol. salts of the acid on sol. Mg salts. Thus, an aq. soln. of Na 1-methyl-4-isopropylbenzene-2-sulfonate is treated with an aq. soln. of MgCl₂ and allowed to stand, when the Mg salt seps. out as colorless crystals. Similarly, Mg sulfonates can be obtained from aq. solns. of Na 1-methyl-2-bromo-4-isopropylbenzene-5-sulfonate and MgSO₄, and from aq. solns. of Na 1-methyl-4-isopropylbenzene-3-sulfonate and MgCl₂.

Methane. COMPAGNIE CONTINENTALE POUR LA FABRICATION DES COMPTEURS ET AUTRES APPAREILS. Fr. 646,782, Dec. 24, 1927. Industrial gases, contg. a large proportion of CO, which are to be enriched in CH₄ are treated in 2 successive phases in the presence of appropriate catalysts, in the 1st of which the gas is enriched in H by the reduction of the steam, added or already contained in the gaseous mixt., by the CO, and in the 2nd the real production of CH₄ takes place.

Formaldehyde. CHEM. FAB. VON HEYDEN A.-G. (Rudolf Gebauer, inventor). Ger. 470,267, May 5, 1923. CH₂O soln. free from CH₂OH is prepd. from aq. aldehyde solns. contg. alc. by mixing with substances contg. alc. OH groups which form addn. compds. with the CH₂O and then segg. the alc. by fractionating. Thus, com. CH₂O is mixed with glycol and the mixt. fractionally distd. Glycerol and grape sugar are mentioned as the added substances in other examples.

Formaldehyde. HOLVERKOHLE-IND. A.-G. (Koloman Roka, inventor). Ger. 467,234, Aug. 29, 1922. CH₂O is prepd. by heating methylene chloride in a closed vessel in presence of water to 140–170°. The liquid must be kept in motion.

Formamide. I. G. FARBENIND. A.-G. Fr. 646,815, Jan. 7, 1928. Formamide is vaporized without decompn. by bringing it into contact with superheated surfaces, preferably under reduced pressure, so that vaporization takes place immediately on coming in contact with the surface without accumulation of liquid in the evaporator. The formamide may be used directly, *e. g.*, for the prepn. of HCN by thermal decompn. in the presence of catalysts.

Acetal. SOC. ANON. DES DISTILLERIES DES DEUX-SÈVRES. Fr. 646,666, Dec. 31, 1927. See Brit. 283,112 (C. A. 22, 3893).

Ether. FIRMA E. MERCK (Wilhelm Welke, inventor). Ger. 468,020, Oct. 17, 1926. Pure ether is preserved by adding a small amt. of tannin, *e. g.*, 1.0 mg. to 1 l. of ether.

Menthol. HANS JORDAN, WALTER SCHOELLER and REINHARD CLERC (to Chemische Fabrik auf Actien vorm. E. Schering). U. S. 1,706,784, March 26. A product of condensation of crude cresol which contains mainly *m*- and *p*-cresol and acetone is heated to about 300° to effect decompn. and the decompn. product is treated with H in the presence of a hydrogenation catalyst such as Ni and Cu, Co or Fe at a temp. of about 140–160° until 8 atoms of H have entered into the mol. combination; the resulting mixt. is then fractionally distd. Cf. C. A. 22, 4134.

Methylene chloride. I. G. FARBENIND. A.-G. Fr. 646,661, Dec. 31, 1927. See Brit. 283,119 (C. A. 22, 3893).

Urea. WARGÖNS AKTIEBOLAG and JOHAN H. LIDHOLM. Ger. 466,263, Sept. 11, 1924. Finely crystd. urea is prepd. from soln. by evapg. the soln. till it contains not more than 10% water and pouring the mass into molds to form blocks which can be granulated. Or the mass can be decanted drop by drop in an atm. of such temp. that the drops congeal as they fall.

Bs-1-Hydroxybenzanthrone and similar compounds. GEORG KRÄNZLEIN, HEINRICH VOLLMANN, HEINRICH GREUNE and ARTHUR WOLFRAM (to Grasselli Dyestuff Corp.). U. S. 1,705,868, March 19. Bs-1-Hydroxybenzanthrone, crystg. from high-boiling solvents as reddish orange needles, m. 317°, is prepd. by condensing anthrone in the presence of H₂SO₄ with acrylic acid dissolved in glacial HOAc at 70–110°, and, generally, a benzanthrone substituted in the Bs-nucleus can be produced by condensing an anthraquinone compd. reduction product contg. O in the central nucleus thereof, for instance an anthrone, anthranol or oxanthranol by means of an acid agent with an α,β -unsatd. carbonyl compd. of the general compn. $\text{RCOCR}^1\text{:CHR}^2$, wherein R stands

for alkyl or aryl or hydroxyl or alkoxy; R^1 stands for any univalent residue, for instance, hydrogen, halogen, hydroxyl, alkoxy, alkyl, aryl, aralkyl, acyl, aroyl, carboxylic ester or the like and R^2 stands for hydrogen, halogen, hydroxyl, alkoxy, alkyl, aryl, carboxyl or carboxylic ester. The reaction between anthrone (or anthranol) for instance and the said α,β -unsatd. carbonyl compds. takes place in such a manner that primarily an addn. of the anthrone to the double linkage occurs with formation of a colorless, well crystg. intermediate product, which intermediate product, in many cases, has *pharmaceutical properties*. Some of these addn. products have already been prepd. by Meerwein (*C. A.* 13, 1310). Contrary to the statement by Meerwein that the said addn. compds., when heated with concd. acids are re-split up into their components, it is stated that from these addn. compds. when working in a suitable manner, *i. e.*, by using an acid condensing agent, there may in all cases be obtained the corresponding benzanthrones by the closure of the ring. Numerous examples and details of procedure are given.

1,6-Dimethylacenaphthenequinone. I. G. FARBERIND. A.-G. (Rudolf Lesser and Georg Gad, inventors). *Ger.* 470,277, Nov. 22, 1925. 1,6-Dimethylnaphthalene is condensed with oxalyl chloride in the presence of a neutral solvent at low temps. by means of $AlCl_3$.

3,6-Tetramethyldiaminodiphenothiazinium cholate. CHEMISCHE FABRIK VORM SANDOZ. *Swiss* 128,326, Dec. 20, 1926. This compd. is prepd. by the action of cholic acid on the diphenothiazinium compd. It melts at 200° with decompn.

Naphthalene-1,5-disulfonyl chloride. I. G. FARBERIND. A.-G. (Bodo Klarmann, inventor). *Ger.* 466,441, Nov. 24, 1925. This substance is prepd. by the reaction of chlorosulfonic acid on one mol. of naphthalene below 100° . Thus, 1. naphthalene is stirred gradually into 400 parts of chlorosulfonic acid at $30-40^\circ$ till HCl ceases to be evolved. The mixt. is then allowed to cool and is filtered. The substance seps. out and is recrystd. from

oil tetranitrate. HENRY A. AARONSON. U. S. 1,705,690, March 19, 1928. When naphthalene is added to concd. HNO_3 and a temp. of about 15° is maintained, the acid and pentaerythritol tetranitrate are sepd. and the latter is freed from water and soda soln.

Acid. HERBERT W. DAUDT (to E. I. duPont de Nemours & Co.). U. S. 1,705,690, March 19, 1928. A reaction is effected between $EtMgCl$ and a Pb salt such as $PbCl_2$ in the presence of $EtCl$ and an alkyl iodide such as MeI . Cf. *C. A.* 23, 1143.

11—BIOLOGICAL CHEMISTRY

PAUL E. HOWE

A—GENERAL

FRANK P. UNDERHILL

Quinine hemolysis; influence of carbon dioxide. W. WEISE. *Abhandl. Geb. Auslandskunde* D26 ii, 5 pp. (1928).—Promotion of quinine hemolysis by CO_2 takes place, if at all, only under extreme conditions. Inhibition by small acid concns., observed by Rusznyák, holds also for CO_2 . The intensity of the hemolysis depends on the amt. of quinine brought into contact with a single blood corpuscle. B. C. A.

Action of formaldehyde on lecithin. Formation of methylated compounds on the organism. W. R. WITANOWSKI. *Acta Biol. Expt.*, Warsaw 2, 61-72 (1928).—Further quantities of choline are produced by the action of CH_2O on com. lecithin contg. cephalin, pointing to the partial conversion of the latter into lecithin by methylation of its free amino group. This increase in choline content varies from 10 to 53% of the original quantity. The optimum pH of the reaction lies between 5 and 7. The quantity of addnl. choline produced does not correspond with the no. of free amino groups present in com. lecithin, indicating either that the reaction does not proceed to completion or that amino-group-contg. impurities other than cephalin are present. The addn. of calf-liver ext. does not increase the yields of choline obtained. B. C. A.

Influence of ions on action of urease. E. M. MYRSKOWSKI. *Acta Biol. Expt.*, Warsaw 2, 211-24 (1928).—The influence of a no. of Na salts on the action of urease on urea was studied. Where inhibition takes place this is proportional to the concn. of salt added, and inversely proportional to the concn. of urease present. Certain salts which at low concns. accelerate the action of urease in every case retard its action at

higher concns. In unbuffered solns. the influence of the salts used, at mol. concns., is in the order of intensity acetate > sulfate > iodide > thiocyanate > tartrate > citrate > nitrate > chloride, while in buffered solns. the order is acetate > sulfate > iodide > thiocyanate > chloride > nitrate > citrate > tartrate. The influence of fluoride is specific, the inhibition curve obtained by adding increasing concns. of this salt being of the adsorption type, pointing to the inactivation of urease by adsorption of fluoride on its surface.

B. C. A.

Acetone and protein. P. CATELANI. *Arch. intern. Pharm.* 33, 420-39(1927); *Physiol. Abstracts* 13, 174.—The action of insulin on acetone *in vitro* was investigated. Acetone disappears in different amts. when mixed with insulin for 12 hrs. at 35°. The quantity transformed varies with the different preps. of insulin. The resemblance of the action of insulin to that of proteins is discussed, and the possible combinations of protein and acetone are considered, such as 2 mols. of acetone combining with protein with loss of a mol. of water. Albumin in soln. can fix or transform acetone and the combination may be chem. or a form of adsorption. Insulin does not affect this fixation. Acetone intoxication in dogs changes the acid-base equil. toward the alk. side.

H. G.

Alkaline hydrolysis of edestin. I. S. YAICHNIKOV. *J. Russ. Phys. Chem. Soc.* 60, 929-32(1928); cf. *C. A.* 22, 1371.—NaOH solns. hydrolyze edestin 3 to 4 times as rapidly as acids of the same concn.

B. C. A.

Biological reactions in gels—the influence of gel density. SILVESTER PRAT. *Kolloid-Z.* 47, 36-8(1929).—Cultures in nutrient media contg. agar responded markedly to variations in the firmness of the gel, tending to cluster with increasing firmness. Addition of salts having no effect on the growth in liquid media caused changes in gel media, presumably by effect on gel firmness. Growth of crystals (pptd. by respiration) was also affected by gel firmness.

G. CALINGAERT

Action of vapors of ethanol, methanol, ether, chloroform, and illuminating gas on isolated leucocytes. C. FORTI. *Atti accad. Lincei* 8, 700-5(1928).—0.10 cc. of leucocytes from *Bufo vulgaris* was suspended in its own serum and placed in a crystg. tube in the presence of vapors of the above substances. Even the vapors from 0.1 to 0.5 cc. of EtOH, MeOH, ether and CHCl₃ paralyze the motions of the leucocytes in about 2 mins. With illuminating gas, however, there is increased motion between 15 and 45 mins., decrease from then on up to 8-9 hrs. when the leucocytes again become paralyzed, but exposure to air causes a partial return of the motion. Exposure beyond 10 hrs. definitely destroys the motion.

A. W. CONTIERI

Occurrence and distribution of iodine in fish and in fish products. GULBRAND LUNDE. *Teknisk Ukeblad* 75, 201-03, 214-6(1928); cf. *C. A.* 23, 1964.—Salt-water fish contain more I than any other article of food examd. Muscle of *Gadus aeglefinus*, *Gadus morrhua* and *Gadus virens* contain, resp., 34.17, 22.20 and 13.37 mg. I per kg. dry substance. In the intestinal canals were found still higher values. Examin. of *Pandalus borealis*, *Asterias*, *Clupea harengus* and phytoplankton shows that the I content of the ocean is concd. in the phytoplankton, which contains 230.91 mg. I per kg. dry substance. To det. the nature of the I combinations the following method was used: The samples were extd. with alc. in a Soxhlet app. on the water bath, and then with CHCl₃. The total CHCl₃-sol. I combinations are characterized as lipid I. In the alc. fraction was detd. I in inorg. form. Then the sample was extd., first, in turn with H₂O, with 25% K₂CO₃ soln. on the water bath, and with cold 5 N HCl. In phytoplankton was found 27.4% sol. in alc. and CHCl₃ (1.5% lipid I), 3.0% sol. in water, 1.8% extd. with 5 N HCl, and 67.8% insol. residue. Norwegian preserved fish contain 0.45 to 6.60 mg. I per kg. dry substance. Cod-liver oils from Norway and New Foundland gave 4.5-15.2 mg. I per kg.

A. DROGSETH

Proteins of the muscle of various animals. K. BECK AND ERICH CASPER. *Chem. Lab. Reichsgsundheitsamts. Z. Untersuch. Lebensm.* 56, 437-57(1928).—Van Slyke N-partitions were made on the flesh of the ox, calf, hog, sheep, horse, goose and codfish. There was remarkable agreement in the several N components and amino acids among the several species of animals.

C. R. F.

Intracellular hydrion concentration studies. I. The relation of the environment to the p_H of protoplasm and of its inclusion bodies. ROBERT CHAMBERS. *Cornell Univ. Med. Coll. Biol. Bull. Marine Biol. Lab.* 55, 369-76(1928).—A study of the relation between the p_H of the protoplasm of a living cell and that of its environment has been made. Of the acids and bases which affect the p_H of the environment some penetrate living cells while others apparently do not possess this property. The presence of CO₂ or of NH₃ in the aq. medium surrounding the living cells readily changes the p_H of the intracellular inclusions which stain with neutral red, but do not change

the p_H of the protoplasm matrix nor of the nucleus as long as the cell is alive. II. The effect of injection of acids and salts on the cytoplasmic p_H of *Amoeba dubia*. PAUL REZNIKOFF AND HERBERT POLLACK. *Ibid* 377-82.—The cytoplasm of the living *Amoeba dubia* shows considerable buffering power to p_H change induced by the injection of salts and buffers. If HCl, injected into the amoeba, is immediately buffered by the cytoplasm, no toxic effect results. If the quantity injected is too great to be buffered, the affected portion of the cell dies, and is discarded. $CaCl_2$, $MgCl_2$, and Al_2Cl_3 , injected into amoeba colored with indicators, give colorimetric evid. of the production of acid greater in amt. than can be explained by acid produc. by mech. injury. Unless the color reverts immediately to that indicative of no. cytoplasm, the affected portion is discarded in the case of $CaCl_2$ and Al_2Cl_3 ; the entire cell dies when $MgCl_2$ is employed. Upon death, permeability changes occur so that the dead mass of the amoeba quickly assumes the H-ion concn. of the environment. III. The buffer action of *Amoeba dubia* and its use in measuring the p_H . HERBERT POLLACK. *Ibid* 383-85.—It is proved that the p_H of the amoeba is not less than 6.6 and not greater than 7.2. The micro-injection technic, with direct color comparison for reading the p_H values, was utilized. Regardless of the p_H value of the buffer soln. injected, the return of color of the indicator is quite rapid and const. If, however, sufficient buffer was applied to change the p_H of the cell, the cell died. Two important facts are emphasized: the cytoplasm has a considerable buffering power, and, when the p_H of the cytoplasm is changed, the cell dies.

FREDERICK G. GERMUTH

The effects of changes in medium during different periods in the life history of *Uroleptus mobilis* and other protozoa. III. The effect of yeast extracts. LOUISE H. GREGORY. Barnard Coll. *Biol. Bull. Marine Biol. Lab.* 55, 386-93(1928). cf. C. A. 20, 3750.—The effect of vitamins on the vitality of protozoa has been investigated. Three different yeast exts. (viz., Alpha bios No. 223, Beta bios and Gamma bios) were prepd. and subsequently employed in the tests. Expts. indicate that while the protoplasm of *Uroleptus mobilis* is usually depressed when treated with yeast exts. probably because of its weakened condition, that of *Dallasia*, *Pleurotrichna* and *Stelodonta* were definitely stimulated by the addn. of fractional exts. of yeast to the normal media. Alpha bios in general causes the least effect and Gamma bios the greatest increase in division rate. Tables furnishing interesting facts relative to this research are given.

FREDERICK G. GERMUTH

Observations on *Hydra* and *Pelmatohydra* under determined hydrogen-ion concentration. W. L. THRELKELD AND S. R. HALL. Univ. of Va. *Biol. Bull. Marine Biol. Lab.* 55, 419-30(1928).—The optimum range of H-ion concn. for both *Hydra viridissima* and *Pelmatohydra oligactis* lies within the range p_H 7.8 and 8.0. Polyps allowed to develop pronounced differentiation and resorption in a high H-ion concn. were induced completely to restore their lost parts when the medium was altered to be within the optimum range of p_H . Dedifferentiation and resorption are induced rather by unfavorable p_H than by inanition.

FREDERICK G. GERMUTH

Further observations on the chemical composition of Woods Hole sea water: the chlorine content and salt analysis. IRVINE H. PAGE. *Marine Biol. Lab. Biol. Bull. Marine Biol. Lab.* 55, 449-52(1928).—The Cl content of Woods Hole sea water has been ascertained over a 3 weeks' period, and shown to be const. within any large range. The method followed was that endorsed by A. O. A. C. (1925). Duplicate titrations were made, and the detns. but rarely disagreed. An analysis of the sea salt is furnished.

FREDERICK G. GERMUTH

The precipitation of calcium and magnesium from sea water by sodium hydroxide. ELEANOR M. KAPP. *Marine Biol. Assoc. Biol. Bull. Marine Biol. Lab.* 55, 451-8(1928).—During the course of an investigation into the modification of sea water for use as a perfusion medium, a knowledge of the relative amts. of Ca and Mg pptd. by NaOH was deemed of importance. Charts are furnished showing the effect of adding varying concns. of NaOH solns. to sea water and exptl. mixts. Mg is rapidly pptd. by NaOH at about p_H 10.2. At a region corresponding to the addn. of 0.1 mol NaOH per l. of sea water, the titration curve begins its second rise, while the Mg curve flattens out. A small quantity of Ca is pptd. throughout; it owes its first pptn. to the insol. of the carbonate, which is intermediate in this respect between $Mg(OH)_2$ and $Ca(OH)_2$.

FREDERICK G. GERMUTH

Permeability differences between nuclear and cytoplasmic surfaces in *Amoeba dubia*. YUN-ICHI MORITA AND ROBERT CHAMBERS. Cornell Univ. *Biol. Bull. Marine Biol. Lab.* 56, 64-7(1929).—*Amoeba*, stained yellow with methyl red and immersed in solns. of HCl, exhibits injury effects by a sudden change in color from yellow to red in localized regions on the periphery. These regions are pinched off and dis-

carded. In a moving amoeba this injury first occurs at the tip of the extending pseudopodia. Sublethal concentrations of HCl which do not penetrate the amoeba from without will, when injected into the ectoplasm, readily diffuse into the nucleus without causing irreversible injury. On the other hand, the wall of the contractile vacuole appears to be similar to that of the plasmalemma of the amoeba in regard to the non-penetrability of HCl.

FREDERICK G. GERMUTH

The culture of *Amoeba proteus* in a known salt solution. D. L. HOPKINS AND PERCY L. JOHNSON. Zoölogical Lab. of Johns Hopkins Univ. *Biol. Bull. Marine Biol. Lab.* 56, 68-73(1929).—A medium, the inorg. compn. of which is accurately known, was devised, in which *Amoeba proteus* grows and multiplies rapidly. By adding KH_2PO_4 buffer gradually, so as to allow time for adaptation on the part of the amoeba, a concn. of buffer may be added which is sufficient to hold the H-ion concn. const., and yet not interfere with the growth and multiplication of the organism. F. G. G.

The hydrolysis of ovalbumin by trypsin, in its relations to the formation of diketopiperazines. A. BLANCHETIÈRE. *Compt. rend.* 188, 112-3(1929); cf. C. A. 22, 1169.—The tryptic hydrolysis of natural and denatured ovalbumin was studied at p_H 8.5 and 38°. The formation of *N*-diketopiperazine from these substances was found to be inverse to that previously observed in the case of peptic hydrolysis. A. G.

The nutrition of *Polytoma uvella* (Ehrenberg) (flagellate chlamydomonadae) and the synthetic power of the heterotrophic Protista—the mesotrophic Protista. ANDRÉ LWOFF. *Compt. rend.* 188, 114-6(1929).—Media are described which are suitable for the growth of *Polytoma uvella*. Such media consist solely of simple org. compds. In this respect *Polytoma uvella* resembles the chlorophyllic autotrophic flagellate of the genus *Chlamydomonas*. The term mesotrophic is, therefore, suggested for the Protista of the type of *Polytoma*, while the term heterotrophic should be limited to the type of Protista exemplified by glaucoma. ARTHUR GROLLMAN

The effects of carbon arc radiation on the blood of dogs. H. S. MAYERSON AND HENRY LAURENS. Tulane Univ. *Am. J. Physiol.* 86, 1-14(1928).—A single exposure to C arc irradiation produced a temporary increase in plasma vol. of 6 to 37% with recovery to normal within 5 hrs. Repeated exposures increased the no. of red blood cells 10 to 19%, maintained for 3 to 6 weeks after the last irradiation. Color, vol. and satn indices showed that the cells in the post-irradiation period were usually smaller and less satd. than before irradiation. Platelets dropped in no. and vol. (35%) during irradiation with recovery usually within 5 hrs. after each exposure. Leucocytosis resulted from moderate irradiation and markedly low levels in the white blood cells followed stronger excessive exposures. Excessive irradiation also appeared to destroy red blood cells. J. F. LYMAN

Penetration of ultra-violet rays through clothing materials. II. HARRIET MORGAN. Utah Agr. Expt. Sta. *Am. J. Physiol.* 86, 32-8(1928); cf. C. A. 22, 3421.—Cottonseed oil was irradiated through cloth filters of various materials and weaves. The treated oils were than fed to rachitic rats and the healing effects noted. Conclusion: The mean interspace between threads and weight are factors limiting the ultra-violet ray transmissibility of clothing material. Kind of material is also an important factor, artificial silk being superior in transmissibility to cotton or mixed cotton and worsted of similar wt. and weave. J. F. LYMAN

The distribution of nitrogen in benzoyl casein. HIDEO KIMURA. Univ. Kyoto. *Acta Schol. Med. Univ. Imp. Kioto* 11, 117-9(1928).—Fifty g. of casein contg. 1.02% ash and 15.92% N (calcd. for ash-free casein) were benzoylated with 9.5 g. BzCl and N NaOH in the cold with the usual technic. The Bz casein contained 1.23% ash and 15.02% N (calcd. for ash-free casein). Then the casein and the Bz casein were analyzed for amino N, humin N, monoamino N, diamino N, histidine N, arginine N and lysine N. It was seen that the corresponding values in both compds. resembled each other closely. Conclusion: The introduction of Bz into casein is not accompanied by a noticeable disintegration of the protein mol. G. SCHWOCH

The enzymic cleavage of the benzoylamino acids. TSUTOMU KAWAI. Univ. Kyoto. *Acta Schol. Med. Univ. Imp. Kioto* 11, 121-9(1928).—The action of trypsin, erepsin and glycerol exts. of fresh pig kidneys and liver on Bz-*dl*-phenylalanine (I), monobenzoyl-*dl*-tyrosine (II) and Bz-*L*-leucine (III) was examd. Neither trypsin nor erepsin had the ability of breaking up the mols. of I, II and III, while the glycerol exts. produced cleavage, III being much more strongly hydrolyzed than I or II. G. S.

The action of erepsin on the dipeptides formed from racemic amino acids. TSUTOMU KAWAI. Univ. Kyoto. *Acta Schol. Med. Univ. Imp. Kioto* 11, 131-5(1928).—To 7 g. of *dl*-tyrosine H_2SO_4 -HCl in 100 cc. CHCl_3 was added with cooling 41 cc. of N NaOH . This mixt. slowly treated with 5 g. $\text{H}_2\text{CClCOCl}$ and 20-cc. soda soln. contg.

4.7 g. Na_2CO_3 , yielded *chloroacetyl-dl-tyrosine Me ester* (I). To prep. *glycyl-dl-tyrosine* (II), I was treated with an excess of aq. NH_3 (d. 0.88). After 3 days the NH_3 was evapd., H_2O added and the soln. filtered. The undissolved residue consisted of *glycyl-dl-tyrosine anhydride* (III), m. 255-7° after crystn. from hot H_2O ; insol. in EtOH and Et₂O, almost insol. in cold H_2O and dil. acids, sol. in alkali. *Glycyl-dl-phenylalanine* as well as II was hydrolyzed asymmetrically by erepsin, the digestion mixt. showing distinct *l*-rotation after a certain time. III was not hydrolyzed by erepsin, trypsin, glycerol exts. from kidneys, yeast press juice and taka-diastase. It was hydrolyzed by heating it with 25% H_2SO_4 under reflux for 14 hrs. G. SCHWOCH

The enzymic cleavage of proteins and peptones. TSUTOMU KAWAI. Univ. Kyoto. *Acta Schol. Med. Univ. Imp. Kioto* 11, 147-54(1928).—K. compared the digestion of gelatin (I), casein (II) and edestin (III) with that of the resp. peptones, using trypsin, erepsin or a combination of trypsin and erepsin as the enzymic agents. The peptones were prepd. by digestion of the proteins with HCl and pepsin. From his results K. comes to the conclusion that II and III are hydrolyzed more easily by the enzymes than are the peptones derived from these proteins, while there is little difference between the cleavage of I and gelatin peptone. G. SCHWOCH

Action of the proteolytic enzymes on the benzoylproteins. TSUTOMU KAWAI. Univ. Kyoto. *Acta Schol. Med. Univ. Imp. Kioto* 11, 267-71(1928).—In comparison with the original proteins, the derivs. of proteins are very resistant against the action of proteolytic enzymes. This fact was confirmed by K. Bz edestin (I) was digested by trypsin to a slightly lesser degree than was edestin (II). Erepsin had a much smaller effect on I than on II. While erepsin and trypsin combined had a greater hydrolyzing action on II than had trypsin alone, their action on I was not different from that of trypsin alone. Bz gelatin (III) was digested by trypsin at about the same rate as was gelatin (IV). Erepsin was almost without effect on III and IV. G. SCHWOCH

The thermodynamic activities of proteins. G. S. ADAIR. *J. Am. Chem. Soc.* 51, 696-707(1929); cf. *C. A.* 23, 323.—Formulas are derived correlating the thermodynamic activities of protein salts with measurements of osmotic pressure. In making a practical application of these formulas to sodium hemoglobinate, it is found that in certain respects, a close resemblance exists between protein salts and typical strong electrolytes. Sodium hemoglobinate, HbNa_n , differs from the latter in that the valence of the Hb ions is neither an integer nor a const., but an av. value, which varies from 0 to 80 according to variations in the activities of Na and OH ions. C. T. S.

Coagulation of blood and milk by electrolytes and the similarity between the clotting of blood and the formation of jellies. N. R. DHAR AND SATYA PRAKASH. *J. Phys. Chem.* 33, 459-66(1929).—Dil. blood and milk are coagulated less readily than concd. blood and milk by such electrolytes as Na citrate, K oxalate, NH_4NO_3 and HCl. The stabilizing effect of small amounts of Na citrate, tartrate, oxalate, etc., during the coagulation of blood and milk by CuSO_4 , is attributed to the adsorption of the negative ions by the particles of blood and milk, and not to the removal of pptg. Ca ions. In general, electrolytes coagulate blood and milk more readily in the presence of saponin or gelatin, except that gelatin has no effect in the presence of HCl. The clotting of blood seems to be guided by the same laws that operate in the formation of jellies of V_2O_5 , ceric hydroxide, silicic acid, etc. CORNELIA T. SNELL

Physicochemical study of proteins contained in the ginkgo. MAKOTO FURUICHI. Tottori Higher Agr. School. *Bull. Tottori Higher Agr. School* 1, 105-22(1928). Ginkgo contains starch 69.6, protein 12, fat 3%, and the ash of the seed contains K 0.406, Na₂O 8.4, CaO 4.8, $\text{Fe}_2\text{O}_3 + \text{Al}_2\text{O}_3$ 3.7, P_2O_5 21.6, SO_3 8.3 and SiO_2 4.9%. Solv. of the degreased sample is greatest in water, next in NaCl soln. and least in alc. Among the 4 proteins (globulin, albumin, protamine, glutelin) globulin is most abundant, of the total N, 60% is present as globulin. F. proposes to name the globulin ginkgoun. Tryp- tophan is contained in globulin in large quantity. On examg. the isoelec. point of each protein by dropping HCl into the alk. soln. it was found that the point of max. surface tension and the max. turbidity are in approx. agreement with each other. The least quantity of HCl is required in globulin, next comes albumin, the largest quantity being required by glutelin. This is supposed to be due to the difference of the amino and carboxyl groups which combine with the acid and alkali. K. SOMEYA

Mechanism of oxidative processes. XV. Nature of the acetic acid fermentation. HEDWICH WIELAND AND ALFRED BERTHA. *Bayr. Akad. Wiss. München Ann.* 467, 96-157(1928); cf. *C. A.* 22, 4320.—A series of investigations has been carried out on the AcOH fermentation by *Bacterium orleanense* (I), the mechanism of which is considered to be $\text{EtOH} (-2\text{H} + \text{O}) \rightarrow \text{AcH} + \text{H}_2\text{O}$; $\text{MeCH(OH)}_2 (-2\text{H} + \text{O}) \rightarrow \text{AcOH} + \text{H}_2\text{O}$. It was found impossible to sep. the enzymes from the bacteria and all

expts. were carried out with suspensions of the bacteria of known concn., buffered to pH 5.6. With EtOH as substrate, the consumption of free O was strictly proportional to time. In the presence of 0.0002 M HCN the velocity fell to 16% of the normal. Titration of the AcOH formed indicated a greater dehydrogenation of AcH than would be expected from its concn. relative to EtOH, an effect which is attributed to the preferential adsorption and reaction of AcH formed on the surface of the same enzyme which catalyzes the 1st stage of the reaction. When benzoquinone was used as H-acceptor in the absence of free O, the dehydrogenation was more rapid, but the same linear relation with time was found. The bacteria were shown to be unaffected by quinone or quinol in the concns. used. The reaction was much less sensitive to HCN than the reaction with free O; a concn. of 0.01 M 1st produced a noticeable retardation. The rate of hydrogenation of the quinone was only slightly lowered by the presence of free O. On the other hand, the free O began to be consumed only when the quinone was practically used up and thereafter was taken up at the normal rate. The same enzyme apparently catalyzes the reaction with both quinone and free O. The linear relation between reaction and time shows that adsorption on the enzyme surface is more rapid than the chem. reaction. Since quinone displaces free O as H-receptor when both are present, quinone must be strongly adsorbed and occupy the surface of the enzyme to the exclusion of O, i. e., it inhibits the O reaction for the same reason as HCN and the reaction with quinone is less retarded by HCN on account of this strong adsorption of quinone. The hypothesis of activation of both the H of the substrate and of free O is rejected; activation of the former alone is considered sufficient. There is no reason why quinone should be able to dispense with an activation inhibited by HCN if mol. O needs it. With methylene blue (II) as H-acceptor the reaction was very slow and its course was not linear. There was evidence of retardation of the reaction by excess of II. The non-linear course of the reaction made observation of times of complete decolorization quantitatively valueless. Retardation by HCN was 1st marked at 0.01 M . With II in the presence of free O, the latter was consumed at the normal rate, while when sufficient HCN was added normally to inhibit reaction with free O, free O was taken up at about 6% of the normal rate. This rate was increased somewhat by increasing the amt. of II and was presumably detd. by the rate of reaction of free O with leuco-II, which was found to be low and little affected by HCN. The interior of the cell, as well as its external walls, is active in the dehydrogenation process. The II is unable to penetrate the walls and reacts only on its outer surface, while mol. O, quinone and HCN can all diffuse into the interior of the cell, where 90% of the action takes place. A parallel series of expts was carried out with AcH as substrate. The reaction was little retarded by HCN and addn. of AcH restored the activity of a mixt., contg. EtOH as substrate, poisoned by HCN. These effects appeared to be due to formation of $MeCH(OH)CN$, which was shown to occur rapidly. The $MeCH(OH)CN$ itself, however, had a minor retarding effect. The course of the reaction of AcH with free O, quinone or II was similar to the reaction of EtOH, although slower. Mixts. of AcH and EtOH consumed EtOH at a rate which was the mean of the rate of consumption by each separately. The 2 reactions are, therefore, brought about probably by the same enzyme. Contrary to Neuberg and Windisch (*C. A.* 20, 929), the Cannizzaro reaction plays little part in the formation of AcOH from AcH. Carefully controlled expts. showed that the rate of consumption of O was naturally about 40 times that calcd. on the basis of dismutation alone, the rate of which was also measured. Similar expts. with *B. pasteurianum* showed that these bacteria brought about dehydrogenation of AcH at 100 times the rate of dismutation. $o-HOC_6H_4CHO$ and $o-HOC_6H_4CH_2OH$ were not dehydrogenated by I. Dithioglycollic acid (III) or cystine did not act as H-acceptors in the presence of EtOH. The dehydrogenation of $(CH_3CO_2H)_2$ by III in the presence of minced liver previously reported is erroneous (*C. A.* 19, 38). The catalase activity of I was also measured. H_2O_2 was rapidly decompd. in a reaction apparently of high order, retarded by HCN. This retardation was parallel to that of the dehydrogenation of EtOH. No free H_2O_2 could be recognized in any of the reaction mixts., whether contg. HCN or not, so that the inhibitory effect of HCN on the dehydrogenase activity must be of the same order. C. J. WESS

Lipases. I. Organ lipases and the inhibition of lipase action by poisons. KEN-SUKE GYOROKU. Univ. of Tokyo. *Proc. Imp. Acad. (Japan)* 4, 503-4(1928); cf. *C. A.* 22, 2579.—Serum and liver lipases are more sensitive to atoxyl than are other lipases. An atoxyl-sensitive lipase on purification becomes atoxyl-refractory. NaF has a poisonous effect on lipases. A poisoned lipase cannot be regenerated by dialysis. II. Determination of lipase in duodenal contents. K. GYOROKU AND SHOICHI TERASHIMA. *Ibid.* 505.—The duodenal contents are approx. diluted with a soln. of equal

parts of glycerol and 1% NH_4 phosphate. The resultant lipase soln. is very stable. The tributyrin method of Rona and Michaelis is used. III. Lipases and proteins. *Ibid* 506-7.—The lipases of blood serum, pancreatic and gastric juices are always found with the proteins pptd. by 60% satn. with $(\text{NH}_4)_2\text{SO}_4$. IV. Separation of lipase into two fractions. *Ibid* 508-9.—The addn. of quinine to gastric or pancreatic lipases yields 2 fractions, each of which alone is inactive but a mixt. of the 2 constituents has a strong lipolytic action. C. J. WEST

The biochemistry of I and the I cycle in nature (LUNDE) 8.

B—METHODS AND APPARATUS

STANLEY R. BENEDICT

Studies in mineral metabolism. IV. Determination of phosphorus compounds in blood by dry combustion. H. H. GREEN. *J. Agr. Sci.* 18, 372-5(1928); cf. *C. A.* 23, 2203.—Total P is detd. as follows: Into a 10-cc. calibrated measuring cylinder contg. a few cc. of water, pipet 2 cc. of citrated blood, make up to the mark with water, invert and mix. Pipet 2 cc. of this laked blood (= 0.4 cc. of whole blood) into a small porcelain dish contg. 2 drops of 10% $\text{Ca}(\text{OAc})_2$, evap. to dryness and ignite the residue. To the ash add 10 cc. of 10% H_2SO_4 , ext. on a steam bath for a few mins. and filter quantitatively into a 100-cc. measuring cylinder, washing up to approx. 60 cc. with cold water. Make slightly alk. with concd. NH_4OH (phenolphthalein), bring to approx. neutrality with a few drops of 10% H_2SO_4 , add 2 cc. of Denig's reagent (*C. A.* 15, 218) and make up to 100 cc. with water. Add 10 drops of fresh SnCl_2 soln. (1%), let stand 10 mins. and compare in colorimeter with a standard prepd. by similar treatment of a soln. of microcosmic salt of known P content. The lipid P is detd. by applying the preceding procedure to the method of Randles and Knudson (*C. A.* 16, 349). The total acid-sol. P is detd. as follows: Pipet 30 cc. of water into a small Erlenmeyer flask, run in 10 cc. of citrated blood and add at once 10 cc. of 20% trichloroacetic acid. Shake vigorously completely to ppt. protein. Allow to stand about $\frac{1}{2}$ hr. and filter. Take 5 cc. of filtrate (= 1 cc. of whole blood) and proceed as for total P. For the inorg. P, pipet 10 cc. of the trichloroacetic acid filtrate into a 25 cc. measuring cylinder, bring to a faint pink to phenolphthalein with NH_4OH , back to colorless with a drop of 10% H_2SO_4 , and add successively 1.5 cc. each of the usual Briggs reagent (*C. A.* 18, 2183), 1% hydroquinone and 20% Na_2SO_3 . The standard is prepd. simultaneously by adding 2 cc. of the trichloroacetic acid soln. to 10 cc. of the standard phosphate soln., neutralizing and adding the reagents precisely as in the case of the unknown. Make both up to the same vol., 17.5 cc., allow to stand 30 mins. and compare. The org. acid sol. P is detd. as the difference between the total acid-sol. and the inorg. P. P. R. D.

Supplementary note on the new ferricyanide method for blood sugar. OTTO POLIN. Harvard Univ. *J. Biol. Chem.* 81, 231-6(1929).—Several factors involved in detns. of blood sugar by the method of *C. A.* 22, 2762 are discussed. The dil. tungstic acid soln. should not be exposed to light nor should a preservative be employed. The Prussian blue employed is held in soln. by means of gum ghatti instead of gum arabic as previously described. ARTHUR GELLMAN

A time method for determination of reducing sugars, and its application to analysis of blood and urine. JAMES A. HAWKINS AND DONALD D. VAN SLYKE. Rockefeller Inst., N. Y. *J. Biol. Chem.* 81, 459-67(1929); cf. *C. A.* 23, 404.—The amt. of sugar present is detd. by the rate at which yellow ferricyanide is decolorized. The accuracy of the method is only $\pm 5\%$ but it is extremely rapid and simple. A. G.

Determination of small amounts of alcohol in the human subject. JOHN EVANS AND A. O. JONES. *Analyst* 54, 134-41(1929).—Slowly evap. 2 cc. of urine at 80° in a current of air which has been passed through concd. H_2SO_4 . Lead the vapors into a mixt. of 15 cc. 0.2 N $\text{K}_2\text{Cr}_2\text{O}_7$ and 20 cc. of concd. H_2SO_4 . Thereby the EtOH is oxidized to AcOH . Titrate the excess $\text{Cr}_2\text{O}_7^{--}$ iodometrically with 0.1 N $\text{Na}_2\text{S}_2\text{O}_3$. The concn. of alc. in the blood attains a max. value about 1.5 hrs. after consumption and falls at the rate of about 12 mg. per hr. per 100 g. of alc. The slower the rate of drinking, the lower the max. concn. Foods, especially bread and milk, lower the concn. of alc. in the blood. If a sample of urine is tested which has been excreted 1.5 hrs. after consumption of the liquor, the quantity of whiskey or beer drunk can be computed with a fair degree of accuracy. Thus 95 cc. of alc. are equiv. to 225 cc. of whiskey and correspond to 200 mg. alc. per 100 cc. of urine. The same amt. of alc. in beer corresponds to 1920

cc. and will show 178 mg. of alc. per 100 cc. of urine. The urine should be tested to make sure that no fermentable carbohydrate is present as this will make the interpretation of the results impossible.

W. T. H.

Electro microanalysis. RUDOLF KELLER. *Naturwissenschaften* 17, 100-3(1929).—A short review of microanalysis in electrobiology. Potentials of living tissues were detd. by indicators and dyes also by actual potential measurements by micromanipulation. From photographs it appears that the honey glands of plants (*Vicia faba*) attract, specifically *in vivo*, neg. dyes because of electrostatic fields. Therefore glucose, which acts as a negative colloid (Stary, C. A. 21, 2590), is attracted. In this migration of substances in and out cells their dispersion is of great importance; Fürth's micro-diffusion app. was used to advantage to det. this factor. B. J. C. v. d. H.

The quantitative extraction of cholesterol and its esters from tissues and body fluids. ERNST MÜLLER. Univ. Marburg. *Z. Biol.* 88, 132-8(1928).—A crit. review of several methods for the detn. of cholesterol with the suggestion that none of the methods which make use of a drying procedure is accurate. FRANCES KRASNOW

An accurate constant-rate injection apparatus. O. S. GIBBS. Dalhousie Univ., Nova Scotia. *J. Pharmacol.* 35, 63-5(1929).

C. RIEGEL

Comparison of assays of adrenaline in the suprarenal extract from oxen, pigs, cats, dogs and rabbits by means of the cat paradoxical eye reaction, the rabbit intestine segment method and the colorimetric method of Folin, Cannon and Denis. TADASHI SUGAWARA. Tohoku Univ. *Tohoku J. Exptl. Med.* 11, 410-32(1928); cf. following abstr.—The adrenaline content was detd. in parallel by the 3 methods, adrenaline chloride of Sankyo Co. being used as the standard. Of the medullary ext. of oxen and pigs the rabbit intestine method gave higher values than the other 2 methods which gave about equal values. Methods of extn. had no apparent relation to the ratios of the values obtained by the 3 methods. The Folin test gave a higher value in cases of cortical tissue than the other 2 tests. With the whole gland of dogs and cats the rabbit intestine method gave a higher value than the others. With ext. of rabbit suprarenals a smaller value was obtained by the rabbit intestine than by the Folin test, even in the medullary ext. The cortical ext. gave a higher value with the Folin test. When the sepn. of the cortical tissue from the medullary tissue was made after the lapse of some hrs the adrenaline by both the Folin and rabbit intestine methods was increased. Therefore, the adrenaline diffuses from the medulla to the cortex after extirpation of the gland. Manipulation of the capsule accelerates this diffusion. The amt. of substance in the cortex, detectable by Folin only but not by the intestine, was unaltered by such handling. Methylaminoacetocatechol-HCl (adrenaline-HCl) reacts to the Folin test with an intensity of about 1 to 2.3 of adrenaline-HCl, but to the rabbit intestine with 1 to 200 of the latter. ω -Aminoacetocatechol-HCl gives a color nearly equal in the Folin test to that of adrenalone-HCl, but has no inhibitory action on the rabbit intestine movements. E. H.

Colorimetric and biological estimation of the adrenaline content of suprarenals, particularly the cortical extract of normal rabbits. MASANOSUKÉ WATANABÉ AND HIROSHI SATO. Tohoku Univ. *Tohoku J. Exptl. Med.* 11, 433-48(1928); cf. preceding abstr.—The colorimetric method of Folin, Cannon and Denis gave a definite positive reaction for the pure isolated cortical suprarenal substance of rabbits, corresponding to about 1 mg. of adrenaline per g. of tissue. The rabbit intestine segment method, blood pressure test and cat paradoxical eye reaction completely failed to show any reaction. For the total suprarenal gland, the Folin method gave much higher values than the biological method. The colorimetric method of Suto and Inouye yielded about the same values as the biological method. E. H.

Examination of hydrogen-ion concentration by means of the micromanipulator.

VI. Experiments on the reaction of tissues. JUNTARO OGAWA. Tokyo Imp. Univ. *Central J. Med.* 26, 899-96(1928).—O. reexamined the Shimidsmann methods of detg. the H-ion concn. by inserting into the cell sap a grain of coloring matter, and compared it with Grift's method. He has described in detail the necessary precautions to be taken in the manipulation. The cell must be as fresh as possible. When it is partially broken the p_H of the cell is rendered acidic and unfit for examn. O. also made a table of the color tones, the use of which is claimed to afford a simpler and more exact p_H detn. K. SOMEYA

The preparation of colloidal gold for the Lange reaction. RAUL WERNICKE AND FERNANDO MONSIEU. *Rep. inst. bacteriol. dept. med. hig.* 5, 19-28(1927).—Many of the recognized methods for the prepn. of gold sols do not give good results in the hands of all workers because of the various factors to be controlled. The authors were able to produce very excellent gold sols for the Lange test by carrying out the electrodialysis

between 2 parchment membranes. The use of collodion membranes gave poor results. The use of glucose in an alk. soln. as a reducing substance also gave a poor gold sol. M. H. SOULE

THOMAS G. PHILLIPS

The occurrence and characteristics of certain yeasts found in fermented honey. GEORGE E. MARVIN. Univ. of Wisconsin. *J. Econ. Entomol.* 21, 363-70(1928).—Thoroughly ripened honeys with a moisture content between 14 and 20% have been found which contain the potential elements for souring. Upon storage and with subsequent granulation of the honey, fermentation may begin. Several yeasts in the group *Zygosaccharomyces* have been isolated and detd. as new to science. Of the 3 known species, only one has so far been found. E. J. C.

Carbon dioxide assimilation. J. BOEDLER. *Bot. Arch.* 20, 143-78, Eng. abstr., 178(1927); *Expt. Sta. Record* 58, 624.—The main portion of this work presents a collective report, claimed to show for the first time the newer assimilation theories combined. H. L. D.

Microchemical studies of rootings and non-rooting rose cuttings. MARGARY C.

CARLSON. Northwestern Univ. *Bol. Gaz.* 87, 64-80(1929).—Dorothy Perkins cuttings (rose) contain more reserve starch than American pillar cuttings. As the starch in the canes is hydrolyzed, the content of reducing sugars increases. Asparagine is abundant in the branches after 8-11 days.

BENJAMIN HARROW

Growth of seedlings in light and in darkness in relation to available nitrogen and carbon. MARY E. REID. Yale Univ. *Bol. Gaz.* 87, 81-117(1929).—Growth of the seedling is influenced by the nature and relative quantities of the food reserves of the seed, as well as by differences in the external environment. Nitrates are synthesized into growth-promoting substances, both in light and in darkness. Nitrates favor the growth of shoots more than of roots. Light strongly favors the growth of roots. Seedlings developed from high-protein seeds benefit most under the influence of light.

BENJAMIN HARROW

Effect of chemical treatment on the assimilation of carbon dioxide. OSKAR WEHNER. *Planta* (Abt. E., *Z. wiss. Biol.*) 6, 543-90(1928).—Leaves of *Fontinalis* and of several mesophytic plants were subjected in a closed system to vapors of H_2SO_4 , HNO_3 , NH_3 and certain other solns. known to retard the assimilation of CO_2 . The degree of injury was detd. qualitatively by the plasmolytic method and quantitatively by dry wt. detns. or by comparing the gaseous exchange of treated and control leaves. Noack's method (*Z. Bot.* 17, 511; cf. *C. A.* 21, 2011) was used for detg. gaseous exchange. After $1\frac{1}{2}$ -2 hrs. of vapor treatment, leaves placed in direct sunlight bleached in 16 or 24 hrs., whereas those left in the dark for 72 hrs. remained normal. HNO_3 , H_2SO_4 and nitrosulfuric acid accelerated, retarded or inhibited assimilation, depending upon the concn. NH_3 and HCl were not stimulating at any concn. Used alone 0.0001 *N* HNO_3 retarded assimilation, but in the presence of 0.1 *N* $NaNO_3$ assimilation was increased by 40%. The addn. of Fe^{++} salts, especially ferroammonium citrate, to these injurious reagents lessened the detrimental effect on assimilation processes. The favorable effect of Fe^{++} salts was more pronounced with *Fontinalis* than with the mesophytic plants. It is still not clear just what part Fe plays in lessening vapor injury, but it is not regarded as a protoplasmic stimulation effect. Plant injury due to vapors emanating from industrial centers may thus be due to 1 or more of many factors, a complex situation which cannot be settled by chem. analysis of the air alone. A. E. H.

Correlation between hydrogen-ion concentration, surface tension, and growth. FERD. HERČÍK. *Planta* (Abt. E., *Z. wiss. Biol.*) 6, 679-83(1928).—When the p_H value of the expressed juice of pea seedlings was varied by the addn. of HCl , surface tension values were changed, reaching a max. at p_H 4.7 which was also the isoelec. point of the juice. Higher surface tension values were obtained for the juice of etiolated seedlings than were obtained for seedlings grown in normal light. It is believed, therefore, that a close correlation exists between the p_H value and surface tension of cell sap and growth. Surface tension detns. were made with du Noüy's app. and p_H detns. were made with the quinhydrone electrode.

Variations in pyrenoids during starch production. FR. STEINECKE AND H. ZIEGEN-SPECK. *Ber. deut. botan. Ges.* 46, 678-81(1928).—When cultures of *Spirogyra grevilleana* and *Zygnema stellinum* are transferred from darkness to light the pyrenoids become smaller and change in shape within 30 secs. This is still noticeable after 30 mins. but after 90 mins. the pyrenoids have their usual form. It is suggested that pyrenoids may play a role in connection with the enzymes of starch production.

L. P. M.

The chemistry of the exudation from the wood of *Pentaspodon motleyi*. A. R. PENFOLD AND F. R. MORRISON. Tech. Museum, Sydney. *J. Proc. Roy. Soc. N. S. Wales* 62, 218-24(1928).—If cuts are made into the heart wood of *P. molleyi* a heavy brown oil may be collected. This oil is non-volatile with steam and cannot be distd. without decompn. It gives a striking color reaction with $FeCl_3$ and is sol. in 8% $NaOH$. Elementary analysis, mol. wt. detn. by the b.-p. method, analyses of the Ag and Cu salts, and detns. of the acid no. and I no. indicate that over 90% of the oil consists of an unsatd. acid, $C_{26}H_{40}O_4$, with 1 $COOH$ and 2 OH groups.

LAWRENCE P. MILLER

Movement of fat in apple shoots. H. D. HOOKER. Univ. of Missouri. *Proc. Am. Soc. Hort. Sci.* 1927, 185-7.—Translocation of fat and N in apple trees was greater in ungirdled trees that bloomed heavily than in those that had little bloom. This indicates that greater storage in the trees that bloomed little the previous season and came

into full bloom the next year. Translocation of fat and N was greater in trees that received $(\text{NH}_4)_2\text{SO}_4$ than in unfertilized trees. The fertilizer treatment was responsible for 0.44 g. more N per 100 shoots being translocated to the tips. J. J. SKINNER

Garlic. V. JUNZO KUROSAWA. *Bull. Research Inst. South Manchurian Railway Co.* 12, 91-130(1928).—When Hg_2SO_4 is used instead of $\text{Pb}(\text{AcO})_2$, HgCl_2 , etc., in the isolation of the principle of garlic, a double compd. contg. Hg is obtained. This was fractionated into many fractions and a detailed examn. of each fraction was made. It is notable that the principle contains not only many common acids, but also such uncommon ones as cysteine, thiolactic acid, a complex organic phosphate contg. N and S (a peptide-like compd. which has not been obtained in a pure state). Cysteine was obtained as large crystals (decompn. temp. $221-3^\circ$), and its properties agree with those of the product obtained by the reduction of cystine as well as with the descriptions in previous literature. More S was found than theory by about 1%. As an explanation of the cause of this phenomenon K. mentions that by virtue of the reactions $\text{RSH} \rightleftharpoons \text{RS}^- + \text{H}^+$; $\text{RSH} + \text{H}^+ \rightarrow \text{R}^+ + \text{H}_2\text{S}$; $\text{RS}^- + \text{R}^+ \rightarrow \text{RSR}$, the neutral soln. of cysteine constantly produces, even when prepd. from other substances than garlic, a small quantity of H_2S gas. From the difference in the properties of the Ag salts thiolactic acid was proved to exist in the α and β forms. The disilver salt of the β -thiolactic acid, b_m 130° , was prepd. and the mechanism of its formation

AgNO_3 AgNO_3

was experimentally proved to be $\text{CH}_3\text{CH}(\text{SH})\text{COOH} \rightarrow \text{CH}_3\text{CH}(\text{SAg})\text{COOH} \rightarrow \text{CH}_3\text{CH}(\text{SAg})\text{COOAg}$. Further, K. compared the action of cysteine, thiolactic acid and H_2S upon photographic plate or $\text{Pb}(\text{AcO})_2$ paper and proved that the aq. soln. of these sulfohydryl compds. slowly produces H_2S , the effect of acid and alkali upon this action being also examd. K. showed that the thiolactic acid has, contrary to the descriptions in the literature, no bad odor, which is produced according to the above-mentioned reaction. Also the reaction toward photographic plate shows the presence of Ag_2S and Ag_2S_2 , with other Ag sulfides. K. SOMEYA

Studies upon wheat grown under constant conditions. I, II. H. L. VAN DE SANDE-BAKHUYZEN. *Stanford Univ. Plant Physiology* 3, 1-30(1928).—A pure strain of Hard Federation wheat was grown under const. conditions of temp. and ventilation in sand, with a 3-salt soln. (compn. not given) having an osmotic pressure of 1 atm. Fe was added as the tartrate. A moisture content of 10% was maintained throughout the expts. Under these conditions ripe (air-dry) seeds were obtained in 72 days. The moisture of the different organs throughout the life cycle was detd. by harvesting 6 plants every other day and later on every 4th or 5th day. Sampling errors were almost entirely eliminated by calcg. the moisture and dry wt. per unit stem length or per unit leaf area and also by calcg. the probable errors. From the lowest to the uppermost leaf, the dry wt. per unit of leaf area increases, while the moisture decreases. Throughout the life cycle the dry wt. of the leaves increases; the moisture increases until the time of flowering. A sudden drop of moisture occurs in all organs of the plant 1-2 days after the stamens have appeared. This drop is most pronounced in the lower leaves, sheaths and internodes. The drying of the plant, which finally causes death, begins, therefore, as early as 1-2 days after pollination, i. e., about the time of fertilization. In explanation of this loss of water, B. advances the theory that the imbibition capacity of the plasma colloids, which is kept up by means of the action of the growth hormones as long as a vegetative point is present, decreases, by the act of fertilization, as soon as this growing point is virtually lost to the vegetative plant. WALTER THOMAS

A method for the determination of inorganic nitrogen in plant extracts. A. C. SESSIONS AND J. W. SHIVER. *New Jersey Agr. Expt. Sta. Plant Physiology* 3, 499-511(1928).—The existing methods for detg. nitrate N in plant tissues are not very accurate (C. A. 15, 488; 17, 2123; 21, 3929). The following modification of the Devarda method gives good results. The water ext. of the plant material is freed from protein by means of 10% acetic acid and afterward concd. to 800 cc. Ammonia is first removed by the Folin aspiration method from a 50-cc. aliquot of the plant ext. to which has been added 50 cc. of a satd. soln. of Na_2CO_3 and 5 g. NaCl . The soln. is aspirated for 12 hrs. and the quantity of ammonia detd. by titration of the standard acid in the absorption tube. The ammonia-free plant ext. is now made 0.125 N with NaOH and 2.0 to 2.5 g. Devarda alloy (100 mesh) is added. The ammonia formed is again detd. by Folin's aspiration method. Nitrates are calcd. from the titration of the standard acid in the absorption tube. The aspirating system used by the authors and the expts. made to test the validity of the method are described in detail. WALTER THOMAS

Two plant material driers. A. O. WOOD. *Grove City College, Penna. Plant Physiology* 3, 515-7(1928).—Description with 4 figures of (1) a hot air drier and (2) a

H₂SO₄ drier devised to hasten the process of drying plant material in the study of their enzyme systems.

Iodometric estimation of Fe [in plants] (GREY) 7. The formation of essential oils and resin in conifers (PIGULEVSKII, RISINA) 17. A discussion of the microflora of alcoholic fermentation (WILLE) 16.

E—NUTRITION

PHILIP B. HAWK

Vitamin A content of flaxseed, flaxseed cake and linseed oil. A. SCHEUNERT. *Züchtungskunde* 4, 30-35(1929).—Linseed fed to rats as a supplement to a diet free from vitamin A proved to be a medium source, while linseed press-cake and linseed oil contain small amounts only, of vitamin A, confirming the work of Drummond and Zilva (cf. C. A. 16, 2164). Hardened fat from linseed oil failed to protect rats from vitamin A deficiency.

BYRON C. BRUNSTETTER

Studies in mineral metabolism. III. Breeding of cattle on phosphorus-deficient pasture. A. THEILER, H. H. GREEN AND P. J. DU TOIT. Div. of Veterinary Services, Onderstepoort, Pretoria. *J. Agr. Sci.* 18, 369-71(1928); cf. C. A. 21, 3070.—On the arid, sparse, P-deficient pasture of the Vryburg district of the Cape Province, grading up of scrub cattle by combining introduction of pure bred bulls with the feeding of bone meal to the cows is attended with great success so far as shown by the first crossing. Remarkable differences in favor of the mineral supplement are shown, in respect to reduced mortality incidence, increased fertility of cows and superior development of calves. V. Composition of bovine blood on phosphorus-deficient pasture. A. I. MALAN, H. H. GREEN AND P. J. DU TOIT. *Ibid* 376-83; cf. C. A. 23, 2198.—The outstanding characteristic of the P partition of the blood of cattle grazing on P-deficient pasture in the Union of S. Africa is a low inorg. P, with correlated reduction in total P. With feeding of a small ration of bone meal comparatively normal values are shown. Heifers nearly 2 yrs. old, thus fed from weaning, show a normal inorg. P fraction of 5 mg. per 100 cc. of blood; control heifers without bone meal show 2.3 mg. Control cows may drop to 1 mg. or less. Calves of control mothers are normal as long as the milk supply is adequate, but may show reduced inorg. P if aphosphorosis of the mother is acute. In general low inorg. P of the blood is assocd. with poor condition of the animal. Long-continued P deficiency leads to clinically recognizable symptoms of the disease, "stysiekte," especially in lactating animals. Less pronounced deficiency is manifested as stunting and malnutrition and can be detected by blood analysis.

P. R. DAWSON

The vitamin A and B content of the pigeon pea (*Cajanus indicus*). CAREY D. MILLER. Univ. of Hawaii. *J. Agr. Sci.* 18, 569-73(1928).—Feeding expts. with rats demonstrated that the plant meal of the pigeon pea (*Cajanus indica*) is a good source of vitamin A, due probably to the large amt. of green leaves in it; but the seed meal is a rather poor source. Both the plant and seed meals are excellent sources of vitamin B, which is characteristic of other legumes.

P. R. DAWSON

Some preliminary experiments on the value of small quantities of whole cow milk when fed to pigs. A. H. BLISSETT AND J. GOLDING. Univ. of Reading. *J. Agr. Sci.* 18, 642-8(1928).—Marked differences were observed when 0.5 pint of milk was fed in addn. to well balanced rations. The total dry matter consumed per lb. increase in live wt. was diminished. This supports the contention that milk may increase the extent to which a given foodstuff is digested.

P. R. DAWSON

Have histidine and arginine an influence on the purine synthesis of the growing human organism? P. GYÖRGY AND S. J. THANNHAUSER. Heidelberg Clinic and Dusseldorf Med. Acad. *Z. physiol. Chem.* 180, 280-304(1929).—From feeding expts. recorded in the literature it appears that histidine and arginine are required for purine synthesis by young growing rats but not by adult rats. In the expts. here described human infants 4-8 months old were used. One group was fed a basal diet of milk and sucrose, and another group a basal diet consisting of butter, Osborne-Mendel salts, and casein hydrolyzate from which the histidine and arginine had been removed by Ag-Ba pptn., and this loss of tryptophan and cystine compensated by addn. of the pure substances. Vitamin requirements were met by suitable addns. of cod-liver oil, yeast ext. and lemon juice. During the 8-14 day feeding periods, 24-hr. samples of urine were collected and detns. made of total N, NH₃ N, uric acid N, creatinine N, pH , acidity by titration and total phosphates. The excretion of uric acid and creatinine was practically the same for the milk diet and the histidine- and arginine-free casein diet. These

values were not altered in either case by the daily addn. of 1 g. histidine-HCl or 0.5 g. arginine- H_2CO_3 , both carefully neutralized.

A. W. DOX

The influence of the amount of food consumed on the growth of an animal. MARGARET C. HOUSE. Iowa State Coll. *J. Home Econ.* 21, 51-3(1929).—Data are presented emphasizing the advisability of keeping accurate food records and the necessity of taking into account the quantities of food eaten when comparing the gains in wt. of exptl. animals.

L. D. ELLIOTT

Rice polishings as a source of vitamin B. A preliminary report. HAZEL E. MUNSELL. U. S. Dept. Agr. *J. Home Econ.* 21, 124-9(1929).—Expts. on rats indicate that rice polishings are a good source of vitamin F but contain very little vitamin G. These terms are used to designate the thermolabile and thermostable factors, resp., of vitamin B.

L. D. ELLIOTT

Some remote effects of deficient diets on the rhythmical movements of the isolated intestine. H. E. MAGEE, WM. ANDERSON AND MISS J. M'CALLUM. Rowett Inst., Aberdeen. *Quart. J. Exptl. Physiol.* 19, 171-9(1928).—In normally fed animals 3 types of rhythm were found: (a) fine contractions, (b) tonus movements of short duration and (c) large sharp contractions, the a movements preponderating. In animals fed on deficient rations various degrees of disordered rhythm were found of a hyper-sensitive or hyposensitive type.

FRANCES KRASNOW

Vitamin B deficiency. STANISLAW K. KON. *Med. Doswiadczalna i Spooleczna* 8, 81-110 (Polish), 111-2 (English)(1927); cf. *C. A.* 22, 2399.—The voluntary food intake of pigeons when kept on a vitamin-B-deficient but otherwise complete synthetic diet was detd. and controlled by the administration of the same amt. of food to pigeons of the same wt. which in addn. received a liberal supply of vitamin B. No difference could be observed in these two groups of pigeons either in the utilization of food or in the rate of passage of a Ba meal through the gastrointestinal tract. The slowing of the passage of a Ba meal observed in the artificially fed birds is due to "barrier action" of the crop. Highly active pancreatic amylase preps. were obtained from the pancreas and intestine of the deficient birds as well as from controls. The view of Randoin and Simmonet that vitamin B controls the carbohydrate metabolism was not corroborated. The lack of appetite for the deficient food and acute nervous symptoms characterize vitamin B deficiency in pigeons. No relation could be found between the occurrence of acute nervous symptoms and degenerative changes in the nerves. Pathological changes due to inanition were present in both groups of pigeons. The role of vitamin B and the true nature of conditions induced by its deficiency are not considered as satisfactorily explained by any of the existing theories.

JAROSLAV KUČERA

Experimental studies on the alipogenetic dystrophy of Bloch. MARCO BERGAMINI. *Biochim. terap. sper.* 15, 396-410(1928).—The purpose was to show that the alipogenetic dystrophy of Bloch is not due to a deficiency in fats but to the absence of vitamins. McCollum's diet No. 3143 was defatted and fed to 24 mice divided into 2 groups of 12 each, a "heavy group" and a "light group." The animals were observed for: general behavior, wt.; radiographic and histologic examns. were made. Symptoms of dystrophy were noted in the "light group" 34 days after the beginning of the expt. At this period 2 mg. irradiated cholesterol was fed daily to each mouse. The results and conclusions are: (a) The syndrome shown by the mice which had been fed with the deficiency diet No. 3143 was similar to the alipogenetic syndrome of Bloch. (b) Irradiated cholesterol had a distinct beneficial action on the animals although the diet was still deficient in fats. (c) The young animals were much more sensitive to the deficiency diet than the adults. (d) A partial dystrophy in the production of the skin was observed in the animals fed with the deficiency diet. The dystrophy described by Bloch is not due to lack of fats, but to a deficiency of fat-sol. vitamins.

P. M.

Experiments on the action of lipoids. I. Weight and cytometric studies on guinea pigs treated with injections of lecithin and esters of cholesterol. ALDO BARCHIESI. *Boll. soc. ital. biol. sper.* 3, 803-7(1928).—Guinea pigs were treated with subcutaneous injections of lecithin for 15 successive days and fed with a normal diet. Other animals received the same diet but no lecithin injections. They served as controls. After 18 days the animals were killed 2 hrs. after the last meal. The animals receiving the lecithin showed a decided increase in wt. up to the 12th day; the wt. became constant for the next 6 days. The deduction is made that the lecithin modified the metabolism up to the 12th day and that afterwards an equilibrium was reached. Two other groups of animals were similarly treated except that the period of observation was prolonged to 42 days. The results were the same. Other expts. were made on fasting animals treated with and without lecithin. The lecithin-treated animals lived an av. of 5.33 days and lost 28.99% of their original wt.; the control animals lived an av. of 7.66 days

and lost 29.51% of their original wt. An examn. of the organs showed a complex mechanism; in the lecithin-treated animals the hepatic cells had a vol. of 4772 cu. microns; in the controls it was 12,292 cu. microns. Data for other organs are given. The conclusion is that lecithin does accelerate metabolic activity but the mechanism is very complex and must be studied further by histological methods aided by qualitative and quantitative chemical analysis. Also in *Rass. clin. terap. sci. affini* 27, 286-322 (1928).

PETER MASUCCI

Pharmacodynamic experiments on a sexual dystrophy of albino rats produced by feeding cereals. PIETRO DI MATTEI. *Boll. soc. ital. biol. sper.* 3, 807-10(1928).—Groups of 18 rats were fed with corn meal and with an appropriate dose (dropwise into the nose) of phosphorated oil, K metarsenite, NaI, Mn lactate, Zn lactate, Fe citrate or K_2SO_4 . None of the drugs had any definite corrective influence on sexual dystrophy. P, Mn and Ca exerted a marked influence on the general development as judged by the wt. but there was no improvement in the sexual development. The only substance which showed a fair activity was I_2 (0.01 g. KI per day). The retardation in growth and the sexual dystrophy of rats fed with cereals is not due to lack of mineral salts but probably to a qual. scarcity of amino acids.

PETER MASUCCI

The antirachitic properties of cod-liver meals. R. M. BETHKE, G. ZINZALIAN, D. C. KENNARD AND H. L. SASSAMAN. Ohio Agr. Expt. Sta. *J. Agr. Research* 36, 747-53(1928).—Dried residues remaining after the extn. of oil from fresh cod livers vary markedly in their antirachitic properties. The variation was not correlated with the residual fat content of the livers. The ether ext. was not as potent as ordinary cod-liver oil.

A. L. MEHRING

Effect of variation of potassium and chlorine in a wheat ration. J. L. ST. JOHN. Wash. Agr. Expt. Sta. *J. Agr. Research* 37, 55-64(1928).—Rats were fed on a basal ration of wheat to which varying amts. of K and Cl were added. When K in the form of $KHCO_3$ was present in excess of 1% of the ration, the rats lost wt. and did not reproduce. Young animals receiving rations contg. 0.4-0.8% K grew normally. K will not replace Na in a ration of wheat. Addition of Cl to the wheat ration was without benefit. Reproduction occurred in some cases but was not correlated with the quantity of Cl in the diet. Twelve references are given.

A. L. MEHRING

The energy metabolism of cattle in relation to the plane of nutrition. E. B. FORBES, WINFRED W. BRAMAN, MAX KRISS, C. D. JEFFRIES, R. W. SWIFT, ROWLAND B. FRENCH, R. C. MILLER AND C. V. SMYTHE. Pa. State Coll. *J. Agr. Research* 37, 253-300(1928); cf. *C. A.* 22, 984.—Five planes of nutrition were studied by methods of direct and indirect calorimetry with steers. The planes were, fasting, and $\frac{1}{2}$, 1, $1\frac{1}{2}$ and 2 times the maintenance requirements. The rations consisted of corn meal and alfalfa hay. Each plane of nutrition was maintained 28 days, the last 3 of which constituted a continuous respiration calorimetry expt. The area of the removed hide was taken as the surface area in computations. The R. Q. and feed residues in the alimentary tract as well as the heat production were used in detg. the fasting catabolism. The heat production was corrected to a uniform live weight and maintenance basis for comparison. Results with duplicate steers agreed exceptionally well. Heat production increased but little from fasting to a half maintenance diet but increased more rapidly as the maintenance level was approached. Above this the increase was much more rapid and at a uniform rate. The relation between heat production and food consumption above equilibrium is expressed by practically a straight line and below maintenance by a pronounced curve. This difference is explained by a new hypothesis not in harmony with the accepted idea. The lower value for fasting is assumed to be due to a specific dynamic effect or energy expense of utilization of body nutrients oxidized. Thus the heat production curve would be influenced by the dynamic effects of the differing proportions of food nutrients to body nutrients and of carbohydrate, fat and protein of body nutrients catabolized at different planes of nutrition. With rise in plane of nutrition, digestible energy rose slightly due to increased digestion of crude fiber and then decreased due to lowered digestion of carbohydrate and protein. The curves of methane, urine and total net energy were nearly straight lines and fell with rise in the plane of nutrition. The net energy values of alfalfa hay and corn meal were 1390 and 3085 Cals. at maintenance and 620 and 2485 Cals., resp., per kg. of dry matter at double the equil. ration. The proportion of gross energy eliminated as CH_4 varied from 6.42 to 9.83%. Comparable detns. of the sp. dynamic effects of feeds or nutrients can be made only at the same plane of nutrition.

A. L. MEHRING

The predominance of diatoms in the origin of cod-liver oil. KNUT WEJDLING. Univ. Stockholm. *Acta Med. Scand., Suppl.* XXVI, 324-34(1928).—The non-irradiated cod-liver oil from fish living at a depth of 100 meters and more, where very few rays

are acting, has the same antirachitic action as ultra-violet radiation. The explanation for this is the fact that diatoms contain 8% fat included in a shell of silicic acid that transmits the ultra-violet radiation, these diatoms forming the food of the fish. Phytosterol is found in considerable amts. in the diatoms living in a layer of the sea where they are exposed to much ultra-violet radiation from the sun. The action of irradiation on the lipoidal material of the living cells was studied photographically by means of the ultramicroscope. The transformation in dark cells is completed in 10 mins. and sometimes sooner. The fat substances then shine like silver and the diatoms either multiply in that stage or, if the radiation was too prolonged, they die but they still shine after death. The pigment, fucoxanthine present in the brown algae is thought to be attached to the activated ergosterol with its 3 unsatd. bonds. The energy liberated from the lipid leads to the depigmentation. This is produced within 10 mins. either by ultra-violet radiation or by ozonization in the dark. This is the time of the max. production of antirachitic action. Longer radiation is injurious, probably owing to the inactivation of ozonides through satn. of C atoms. S. MORGULIS

Feeding experiments on rats with oils and fats. E. FRIEDBERGER AND S. SEIDENBERG. Forschungsinst. für Hyg., Berlin-Dahlem. *Biochem. Z.* 200, 289-97 (1928). — Rats fed a diet of oats and bread contg. pure olive and cod-liver oil show considerable inhibition of growth as compared to rats receiving the same basic diet without the fat. This effect is produced whether the fat is fed naturally or by means of the tube, except that in the last case the peculiar skin effects do not appear. Similar results so far as the skin is concerned were also obtained upon feeding bacon fat or butter though the growth curve showed a much more favorable progress. S. MORGULIS

Estimation of vitamin A in cod-liver oil. Comparison between the colorimetric (Rosenheim, Drummond) and the biological methods. F. GOWLAND HOPKIN AND HARRIETTE CHICK. *Lancet* 1928, I, 148-50. — The same set of oils, one furnished by H. H. Dale and 6 by Prof. Poulson, were tested by different labs. The colorimetric tests were made by O. Rosenheim; the biol. tests by J. C. Drummond, E. Mellanby, V. H. Mottram and Sir Charles Martin. The $AsCl_3$, the $SbCl_3$ and the biol. methods used are described in detail. The colorimetric method gives information consistent with that derived from the biol. tests. There was a marked variation in the values obtained by the biol. method in different labs. for the same oil. The Accessory Food Factors Committee considers that more tests should be made by the colorimetric method on substances contg. vitamin A other than cod-liver oil, such as butter, palm oil, cereal oils, etc. F. B. SEIBERT

The relative content of the fat-soluble vitamins A and D. JOAN LEIGH CLARE AND KATHARINE M. SOAMES. *Lancet* 1928, I, 150-2. — The same 7 oils as tested by the Accessory Food Factors Committee (*Lancet* 1928, I, 148-50) were tested for their relative content of the 2 vitamins A and D. Vitamin A was detd. by the amt. of growth on a regulated dose. Vitamin D was assayed in 3 ways, (1) by the amt. of calcification occurring on a low-P, rickets-producing diet, to which were added small doses of the oils, (2) by detg. the ash content of the bones of animals fed on a diet not producing rickets and to which were added small doses of the oil, (3) by detg. the increase in the body wt. The degree of accuracy in these biol. methods is very small, but there is no doubt that the content of vitamin A in cod-liver oils bears no necessary relationship to that of vitamin D. F. B. SEIBERT

Comparative antirachitic value of various marine animal oils and cod-liver oil. MME. L. RANDOIN, E. ANDRÉ AND R. LÉCOQ. *J. pharm. chim.* 7, 529-39 (1928). Four fish oils from the livers of the following species were given chem. and biol. exams: (I) Haddock (*Merluccius merluccius* L.) from Lorient, 1926; (II) small shark (*Squalus Galus canis* Rondelet), Boulogne-sur-Mer 1926; (III) elephant seal (*Macrorhinus lewinus* L.) Kerguelen Islands 1926, and (IV) amber cod-liver oil of good type and known activity (detd. C. A. 21, 601). The chem. and phys. properties of these oils, resp. were: d_{20} , 0.9259, 0.9229, 0.9195 and 0.9243; n_D^{20} , 1.4809 (17°), 1.4787, 1.4741, 1.4790 (15°); $[\alpha]_D^{20}$, -0°, 34', -0°, 30', 0°, -0°, 19'; sapon. no., 175.0, 179.5, 182.2, 181.1; I no. (Hanus), 163.7, 191.0, 116.2, 148.7; acidity (calcd. as oleic acid), 2.85%, 0.20, 0.65, 3.75%; fatty acids 95.3%, 96.1, 97.0, 96.4%; unsapond., 3.3%, 2.35, 1.5, 2.4% I was liquid at 0°; II, m. 23-5°; III, m. 23-4°. The antirachitic power of these oils was tested on white rats in parallel sets with a view of detg. the preventive and the curative effects. The rachitic effect was produced with diets D (Pappenheimer, McCann and Zucker, C. A. 16, 1607) and RL (R. and L., C. A. 22, 2193); both diets gave about equal results: (1) The curative and preventive action of cod-liver oil was plainly noted. (2) Feeble doses (2% of the diet) of the oils examd. apparently had no clearly preventive effect. Larger doses (10%) gave after 20-25 days a pos. result with I and II, a neg.

result with III. (3) The curative action of III is nil; that of I and II, based on the rapidity of calcification, was, resp., 10% and 5% of the normal activity of cod-liver oil. However, as I and II were collected late in summer after the spawning season when the livers were small, oils obtained in the spring when the livers are large probably will show greater activity. Only oil of known origin should be collected, and its quality detd. by biol. tests. There is no close relation between the efficacy of these oils and their chem. and phys. characters.

S. WALDBOTT

F—PHYSIOLOGY

E. K. MARSHALL, JR.

The energy changes of skeletal muscle accompanying contraction under high pressure. MCKEEN CATTELL AND D. J. EDWARDS. Cornell Univ. Med. School. *Am. J. Physiol.* 86, 371-82(1928).—Frog's gastrocnemius muscle stimulated in a chamber under a hydrostatic pressure of 60 atm. produced in single contractions about 30% more heat and developed about 30% more tension than under normal conditions. Increased pressure had no effect on muscular efficiency, tension or heat produced during a prolonged contraction (tetanus). The results accord with the theory that stimulation increases the permeability of certain boundaries in the muscle permitting lactic acid to come into contact with the contractile mechanism. Under increased pressure the period of increased permeability seems to be increased.

J. F. LYMAN

Initial and recovery heat production in smooth muscle based upon experiments on a urinary bladder-nerve preparation from terrapin. C. D. SNYDER AND F. W. LIGHT, JR. *Am. J. Physiol.* 86, 399-422(1928).—The smooth muscle from the bladder of the terrapin was made to contract (1) in air, and (2) in N_2 after treatment of the muscle with cyanide and (3) in O_2 . The initial heat was nearly all anaerobic and per g. of muscle and per g. of tension was of the same magnitude as that for skeletal and cardiac muscles. Smooth muscle, like skeletal and cardiac muscle, liberated considerable delayed anoxidative heat, the mean value of which was greater than for the striated muscles. Oxidative delayed heat was considerably less for bladder muscle than for skeletal muscle. Whether the recovery processes are different in smooth and in striated muscles awaits further study. The results suggest a fundamental difference in the 2 muscles in such qualities as the kinds and amts. of the oxidative catalysts.

J. F. L.

Muscular activity. I. Determination of the rate of circulation of blood in man at work. A. V. BOCK, D. B. DILL AND J. H. TALBOTT. Harvard Univ. and Mass. Gen. Hosp. *J. Physiol.* 66, 121-32(1928).—App. and methods for detg., during exercise, the CO_2 pressure in oxygenated venous blood are described. The CO_2 pressure in arterial blood is detd. from the compn. of alveolar air. The CO_2 transported per 1000 cc. of blood is then calcd. from the difference between the CO_2 pressure of the venous and arterial blood and the CO_2 dissoen. curve of oxygenated blood. The total CO_2 production divided by the CO_2 transported per 1000 cc. of blood gives the blood flow. II. A nomographic description of expired air. D. B. DILL AND A. FÖLLING. *Ibid* 133-5.—A simplified D'Ocagne nomogram is described from which, the compn. of the expired air being known, one can read directly both the % of O_2 used and the respiratory quotient. III. Dynamical changes occurring in man at work. A. V. BOCK, C. VAN CAULAERT, D. B. DILL, A. FÖLLING AND L. M. HURXTHAL. *Ibid* 136-61.—Measurements on 4 subjects showed that phys. training increased lung capacity, induced a slow pulse rate, increased the stroke vol. of the heart, reduced systemic blood pressure during work and probably greatly increased the capillary diffusion area in the muscles as it did in the lungs. Failure to meet O_2 requirements in an untrained subject was reflected in a short time in the accumulation of lactic acid, diminution of blood bicarbonate, a falling pH , and a tendency to reach max. pulse and respiratory rates at levels that produced almost no embarrassment for the athlete. IV. The "steady state" and the respiratory quotient during work. A. V. BOCK, C. VAN CAULAERT, D. B. DILL, A. FÖLLING AND L. M. HURXTHAL. *Ibid* 162-74.—During continuous muscular exercise when a steady state was reached and the demand for O_2 was adequately met, the respiratory quotient of the excess metabolism due to work approached unity. Glycogen or some substance very closely related to it in normal metabolism is the immediate source of the energy of muscular contraction.

J. F. LYMAN

Studies in mineral metabolism. VI. Comparison of the blood of cow and calf in respect to mineral constituents. H. H. GREEN AND E. H. MACASKILL. *J. Agr. Sci.* 18, 384-90(1928); cf. *C. A.* 23, 2203.—The total P of the blood of the new-born calf may be over twice that of the mother, appearing to rise somewhat for the

1st few days and then falling steadily to as low a difference as 15% after 10 weeks. After weaning there may be hardly any difference. Although the total P of the plasma is also higher in the young calf, the main difference is in the red corpuscles and is largely accounted for by the org. acid-sol. fraction (phosphoric esters). This org. acid-sol. P appears to be confined to the corpuscles in both calf and mother and is over 3 times as high in the calf at birth. It then falls steadily. The red corpuscles of calf blood may also show an unknown P fraction, insol. in acid and probably of nuclear origin. The lipoid P fraction in the blood of the calf at birth may be similar in amt. to that of the mother or may be higher. It tends to rise over the 1st few weeks of life and may remain high for months, or may fall again. It appears to be distributed as about $\frac{1}{2}$ in the plasma and $\frac{1}{2}$ in the corpuscles. The inorg. P fraction of the new-born calf is appreciably higher than that of the mother, rises sharply within the 1st week, begins to fall again during the 2nd month and even after 10 weeks is still high. The inorg. fraction appears to be confined to the plasma, with very little in the corpuscles. The outstanding feature of calf blood is its very high K content, nearly twice as high for the plasma and over 4 times as high for the red corpuscles. This high value falls rapidly and after 10 weeks calf blood can be regarded as adult in respect to K. More than 0.8 of the total K may be locked up in the corpuscles. No characteristic differences in Ca, Mg, Na and Cl were shown between the blood of calf and mother. About $\frac{1}{2}$ of the Mg is in the corpuscles; about $\frac{1}{4}$ in the plasma. The Na is chiefly in the plasma; the Ca and Cl are exclusively so. VII. The unknown phosphorus fraction of calf blood. A. I. MALAN AND H. H. GREEN. *Ibid* 391-6.—An unknown P fraction frequently present in calf blood is shown to be nucleoprotein and due to the precursors of fully mature erythrocytes. The same fraction may also appear in small quantities in human blood and in horse blood; it always occurs in very large amts. in the nucleated erythrocytes of birds. VIII. Comparison of phosphorus partition in the blood of calf fetus, sheep fetus, and lambs, with corresponding maternal blood. A. I. MALAN. *Ibid* 397-400.—In respect to the P partition, the same general relationship holds between the blood of lambs and of the mother ewes, as between the blood of calves and of mother cows. A considerable proportion of an acid-insol. P fraction, probably nuclein, may be present in the red corpuscles of lamb blood and even in fetal blood. The org. acid-sol. fraction is confined to the corpuscles, both in young and adult blood, but in 1 case of a 6 months calf fetus a small proportion was noted in the plasma. P. R. D.

Color changes and adrenaline content of rabbit suprarenals after ligation of kidney vessels on both sides. MASANOSUKÉ WATANABÉ. Tohoku Univ. *Tohoku J. Exptl. Med.* 11, 449-67(1928).—The kidneys vessels on both sides in the rabbit were ligated, and as the blood sugar reached its max., the animal was killed by neck stroke, the suprarenals were removed and their adrenaline contents were detd. by both the Folin and rabbit-intestine-segment methods. Ligation of the kidney vessels had no apparent effect on the adrenaline content or the color changes of the gland. E. H.

G—PATHOLOGY

H. GIDEON WELLS

Studies in mineral metabolism. IX. The phosphorus partition of blood in anemia of cattle and sheep. A. I. MALAN. *J. Agr. Sci.* 18, 401-5(1928); cf. *C. A.* 23, 2207.—In cases of anemia in cattle and sheep of infectious or parasitic origin, or due to simple hemorrhage, the P partition of the blood reveals an "unknown fraction," confined to the corpuscles and evidently nucleoprotein. It is detd. by the difference between the total P and the sum of the total acid sol. and lipoid P. It is associated with the appearance of nucleated red cells and vanishes as they disappear. The amt. may make up a considerable proportion of the total P. P. R. DAWSON

Sulfate retention in dogs following bilateral adrenal extirpation. W. W. SWINBUR AND W. F. WENNER. Univ. of Iowa. *Physiol. zool.* 1, 37-44(1928); *Ber. ges. Physiol. exptl. Pharmacol.* 45, 666.—Sulfate detns. were made by the Denis and Reed method in 25-cc. blood removed from the heart. As soon as the first symptoms of adrenal insufficiency are evident, there was present a retention of inorg. sulfate S. Parallel with this increase there is an increase in the inorg. P and N. The retention of the SO_4 and PO_4 explains the acid intoxication of adrenal insufficiency. Org. acids play a much less important role. Outside of certain types of nephritis with N retention and acidosis, adrenal insufficiency appears to be the only cause for a SO_4 retention. R. C. WILLSON

H—PHARMACOLOGY

A. N. RICHARDS

Toxicology of certain chlorine derivatives of methane and ethane. G. A. HALOFF. *Arch. exptl. Path. Pharmacol.* 134, 168-72(1928).— CHCl_3 and CCl_4 produce fatty degeneration of the liver, while dichloromethane, ethylene dichloride, ethylidene chloride, and hexachloroethane have no such action.

B. C. A.

Fatal phenobarbital poisoning. Report of a case with toxicologic analysis. HAROLD N. WRIGHT. *Arch. Internal Med.* 43, 85-9(1929).—A method for the analysis and isolation of phenobarbital from the organs in a case of poisoning by this drug is described. The approx. amts. isolated per 100 g. tissue were: stomach 3-4 g.; liver 5 g.; brain 90 mg. Phenobarbital is not excreted in the urine.

J. B. BROWN

Mustard gas and tuberculosis. AMOS R. KOONTZ. *Arch. Internal Med.* 43, 90-5(1929).—168 rabbits were inoculated in the ear vein with virulent human tubercle bacilli. Half of these were gassed with mustard gas and the remainder kept as controls. At the end of 6-10 weeks 64% of the gassed animals had developed tuberculosis as against 83% of the controls. Mustard gas has an inhibitory effect on the development of pulmonary tuberculosis in rabbits.

J. B. BROWN

Estimation of thallium and its toxicology. C. STICH. *Pharm. Ztg.* 4, 231(1929); cf. *C. A.* 23, 1590.—Some addnl. data are presented relative to the toxicity of Tl-treated wheat grains on rats.

W. O. E.

Results obtained by the administration of daily small doses of quinine, cinchonidine and cinchonine on malaria in Algerian natives. E. SERGENT and A. CATENEL. *Arch. Inst. Past. Algerie* 4, 35-48(1926); *Rev. hyg. méd. prat.* 51, 68.—Cinchonidine had a more marked effect than cinchonine, which possesses only a feeble action on parasites in the peripheral blood. Cinchonidine and quinine act very similarly as malaria treatments for malaria.

C. R. F.

An active influence of organic lead compounds on experimental carcinoma in mice. ERICH KRAUSE. *Tech. Hochschule, Berlin. Ber.* 62B, 135-7(1929).—The following compds. were investigated as regards their toxicity and chemotherapeutic effect on exptl. carcinoma in mice: $(n\text{-C}_4\text{H}_9)_2\text{PbF}$, $(i\text{-C}_4\text{H}_9)_2\text{PbBr}$, $(i\text{-C}_4\text{H}_9)_2\text{PbI}$, tricyclohexyllead, tricyclohexyllead iodide, triphenylcyclohexyllead, $(\text{C}_6\text{H}_5)_3\text{Pb}$, $(\text{C}_6\text{H}_5)_2\text{Pb}$, $(\text{C}_6\text{H}_5)_2\text{PbBr}$, $(\text{C}_6\text{H}_5)_2\text{PbI}$, $(\text{C}_6\text{H}_5)_2\text{PbF}$, $(\text{C}_6\text{H}_5)_2\text{PbBr}_2$, $(\text{C}_6\text{H}_5)_2\text{Sn}$, $(\text{C}_6\text{H}_5)_2\text{SnBr}$ and $(\text{C}_6\text{H}_5)_2\text{SnI}$. The toxicity was dependent on the structure of the compd. rather than on its soly. in H_2O . Several of the compds., particularly $(n\text{-C}_4\text{H}_9)_2\text{PbF}$, showed prophylactic and curative effects against carcinoma in mice.

ARTHUR GROLLMAN

Guanidine structure and hypoglucemia. FRITZ BISCHOFF, MELVILLE SAHYUN and M. LOUISA LONG. Santa Barbara Cottage Hosp. *J. Biol. Chem.* 81, 325-49(1929).—A comparative study was made of the hypoglucemic activity of guanidineformic acid and its homologs, of aromatic guanidine bases, of synthalin homologs and other aliphatic guanidine bases. The basic derivs. with long aliphatic side chains had the most powerful hypoglucemic action. The derivs. of guanidineformic acid and its homologs were non-toxic. Hypoglucemic activity, lethal dose and liver damage ran nearly parallel. In all the derivs. except guanyl piperidine, in which hypoglucemia occurs the first hr., the glycogen reserve of the body was almost depleted before hypoglucemia occurred. Since the guanidine derivs. produce hypoglucemia by mechanisms other than glyconeogenesis, there is a possibility of their chem. relation to insulin.

ARTHUR GROLLMAN

The effect of insulin on the distribution of non-protein nitrogen in the blood. STANLEY E. KERR and VARTAN H. KRIKORIAN. Am. Univ. of Beirut, Syria. *J. Biol. Chem.* 81, 421-4(1929).—After the administration of insulin, there is a decrease in the amino acid N with a correspondingly larger increase in the urea N of the blood.

ARTHUR GROLLMAN

The influence of iodine on the excretion of creatine in exophthalmic goiter. WALTER W. PALMER, DONALD A. CARSON and LAWRENCE W. SLOAN. Columbia Univ. and the Presbyterian Hosp., N. Y. *J. Clin. Investigation* 6, 597-608(1929).—Administration of I markedly diminished the creatinuria in the cases of exophthalmic goiter, and "toxic adenoma" which were studied.

ARTHUR GROLLMAN

Studies on digitalis in ambulatory cardiac patients. II. The elimination of digitalis in man. HARRY GOLD and ARTHUR C. DE GRAFF. Bellevue Hosp. and Cornell Univ., N. Y. *J. Clin. Investigation* 6, 613-26(1929).—The excretion of digitalis at any given time was found to be proportional to the amt. of this substance present in the body at that time.

ARTHUR GROLLMAN

Biochemical studies on creatine and creatinine. I. NOBORU SATO. Tokyo Jikeikai Med. Coll. *Sei-I-Kwai Med. J.* 47, No. 10, Eng. Abstr. 1-2(1928).—Creatine

administered to rabbits is in part retained as such, in part converted to creatinine and in part excreted in the urine. After oral administration, the creatine contents of the kidneys and liver are increased; the muscle creatine increases until it reaches a max. after 12 hrs. and then it usually decreases. After oral administration of creatinine the urinary excretion of this substance is greater than the excretion of creatine after oral administration of the latter substance. Intravenous injection of creatine or creatinine leads to a greater urinary excretion and a lesser retention of these substances, than when equal dosages are administered orally.

ARTHUR GROLLMAN

Thyroxine studies. Thyroid gland action and nourishment. Dosage of thyroxine. W. KORNFIELD AND E. NOBEL. Univ. Clinic, Wiert. *Klin. Wochschr.* 7, 2377-80 (1928).—The minimum lethal dose of thyroxine for 200-250 g. guinea pigs that are on a milk-oat diet is 10-20 mg. The toxicity of thyroxine or of dried thyroid preps. is largely dependent upon the diet. Fairly constant results are obtained with animals that are on a milk-oat diet. Green fodder raises the resistance of guinea pigs to thyroxine; the variations are very large. Thyroxine is more toxic when injected into than when fed to animals on green fodder. These two modes of administration are about equally effective when the animals are on a milk-oat diet.

MILTON HANKE

The treatment of encephalitis e causa ignota with intravenous injections of urotropine solutions. P. H. OLIVIER AND P. M. VAN WULFFTEN PALTHE. *Geneeskund. Tijdschr. Nederland.-Indië* 68, 1023-35 (1928).—In 5 cases of encephalitis e causa ignota, and 1 case of myelitis transversa the authors got excellent results with intravenous injections of urotropine. In all cases 4 to 6 injections were given of a 20% soln. daily or at longer intervals, dependent on the condition of the patient. There was a rapid improvement. Little children and babies can be treated without danger; 1 cc. of a 20% soln. and even a 40% soln. may be used each time. No success was encountered with several cases of encephalomeningitis and 2 cases of meningitis tuberculosa. J. C. JURRIJENS

A case of fatal heroine poisoning. LOUISA KOHLBERG AND GOTTFRIED BECK. Univ. Zurich. *Deut. Z. ges. gericht. Med.* 12, 112-20 (1928).—Case report. F. K.

The determination of nervous disorder after carbon dioxide poisoning. FRIEDE RICH LEPPMANN. *Deut. Z. ges. gericht. Med.* 12, 121-32 (1928). FRANCES KRASNOW

Changes in the kidneys due to mercuric chloride poisoning. B. A. PHOTAKIS AND EM. NIKOLAIDIS. Univ. Athens. *Deut. Z. ges. gericht. Med.* 13, 28-32 (1929). HgCl₂ injuries not only the secretory epithelium but also the vascular system. This should be called angionephrosis.

FRANCES KRASNOW

Studies in malaria with special reference to treatment. VI. The treatment of benign tertian malaria with peracrina 303. J. A. SINTON, W. BIRD AND S. N. EATE. *Indian J. Med. Research* 15, 277-86 (1927).—Peracrina 303 cannot be substituted for quinine. VII. The intravenous injection of sodium stovarsol in the treatment of benign tertian malaria. J. A. SINTON. *Ibid* 287-99.—The results obtained from a study of 25 cases show that the intravenous injection of sodium stovarsol in varying doses up to a total of 4 g. during 5 days has produced a "true cure" in a very small no. of cases. VIII. The oral administration of quinine-stovarsol in the treatment of chronic benign tertian malaria. J. A. SINTON, W. BIRD AND S. N. EATE. *Ibid* 595-600 (1928).—Stovarsol is a useful adjuvant to quinine. Quinine stovarsol does not seem to be more efficacious than the two drugs given separately but it is more easily administered.

FRANCES KRASNOW

The pharmacological action of quinamine. R. N. CHOPRA AND J. C. DAVID. Calcutta School of Trop. Med. *Indian J. Med. Research* 15, 343-8 (1927).—Quinamine occurs in appreciable quantities in cinchona bark produced in India. The alkaloid has little effect on bacteria, protozoa and digestive enzymes. It stimulates the peristaltic movement of the intestine. Intravenous injections cause an increase in the vol. of the spleen and stimulate its contractions. The blood pressure falls but soon regains normal level. Respirations are slowed and there is slight but persistent dilation of the bronchi. On the uterus the effect is pronounced; dilns. of 1-500,000 produce a well marked tonic contraction of the isolated uterus of cat and guinea pig. The anesthetic action of quinamine on the cornea and blocking of impulses in nerve trunks is almost as marked as that of cocaine.

FRANCES KRASNOW

Studies on the effects of antimony salts. I. The effect of antimony salts on conception and pregnancy in animals. E. C. HODGSON, A. C. VARDON AND ZORAWAR SINGH. *Indian J. Med. Research* 15, 491-5 (1927).—Salts of Sb cause damage to female animals while they are receiving these periodic injections. The damage shows itself in failure of conception, abortion, damage of fetus. The effect passes off directly as injections are stopped.

FRANCES KRASNOW

Sodium hydnoearpate in leprosy. Suggested improvements in administration.

E. MUIR. Calcutta School of Trop. Med. *Indian J. Med. Research* 15, 501-5(1927).—The sodium salts derived from the low m. p. fatty acids of *Hydnocarpus wightiana*, *H. anthelmintica* and *H. alpina* block the veins less than the salts from the whole *H. wightiana* oil. Alternation of intravenous infiltration of hydnocarpus oil with cresote is advised.

FRANCES KRASNOW
The iodide-antimony treatment of leprosy. E. MUIR. Calcutta School of Tropical Medicine. *Indian J. Med. Research* 15, 507-10(1927).—A combination-treatment of KI and K₂Sb tartrate was found beneficial.

FRANCES KRASNOW
Provocative action of organic compounds of antimony in leishmaniasis. R. N. CHOPRA AND C. R. DAS GUPTA. *Indian J. Med. Research* 15, 565-70(1928).—Sb compds. have a provocative action in those cases of kala-azar in which the fibrotic changes in the liver and spleen are not too far advanced.

FRANCES KRASNOW
A comparative study of the action of cinchonia alkaloids on the uterus. R. N. CHOPRA, J. C. DAVID AND B. B. DIKSHIT. Calcutta School of Trop. Med. *Indian J. Med. Research* 15, 571-80(1928).—The cinchona derivs. stimulate the guinea-pig uterus to a greater degree than that of the cat. The latter acts best at pH 7.6, the former at 7.2. The dextro-rotatory alkaloids have a more powerful effect than do the levo-rotatory. They may be grouped in this order of activity: quinamine, ethylhydrocupreidine, isoctylhydrocupreine or vuzine and cinchonine, ethylhydrocupreine, quinine and quinidine, cinchonidine, isoheptylhydrocupreidine and isoheptylhydrocupreine. F. K.

The action of emetine on the gastrointestinal tract. R. N. CHOPRA, J. C. GUPTA AND K. VENKATACHALAM PILLAI. Calcutta School of Trop. Med. *Indian J. Med. Research* 15, 883-8(1928).—Traces (1 in 200,000) inhibit the action of ptyalin. Peptic digestion is stimulated by concns. higher than 1 in 2000; weaker solns. have no effect. Proteolytic and lipolytic digestions are inhibited by concns. below 1 in 10,000. A technic was devised by which simultaneous tracings of the different portions of the alimentary canal could be recorded after intravenous administration of emetine. Tone and movement of the gut are stimulated. The effects are due to the action of the alkaloid directly on the musculature of the tract and not through the nervous mechanism. F. K.

Results of trials of sodium hydnocarpate and Bruschetti vaccine in leprosy. C. B. LARA, B. DEVERA AND F. EUBANAS. Culion Leper Colony. *J. Philippine Islands Med. Assoc.* 8, 261-3(1928).—No definite effect was produced. FRANCES KRASNOW

The influence of thyroid preparations upon the cardiac and vascular nerves. HENRY DRYERRE. Edinburgh Univ. *Quart. J. Exptl. Physiol.* 19, 61-83(1928).—Thyroid ext. injection produces a fall in blood pressure in cats and dogs, not in rabbits. The injection has no const. specific effect on the response to subsequent stimulation of the cardiac fibers of the vagus. Exts. of liver or tonsil may or may not be followed by effects on the cardiac nerves. Thyroxine has no distinct effect. FRANCES KRASNOW

Studies on the Arnetz count. XII. The effect of the injection of thyroid extract on the polynuclear count in a perennibranchiate amphibian (*Necturus maculosus*). HARRY A. CHARIPPER. New York Univ. *Quart. J. Exptl. Physiol.* 19, 109-13(1928).—The normal count is similar to that in man and in rabbits. Injections of thyroid substance into the peritoneal cavity cause a deflection of the polynuclear count—an increase in the no. of cells of class I. Thyroid ext. will stimulate granulocytopoietic centers located in places other than the bone marrow. FRANCES KRASNOW

The action of drugs upon the movements of the stomach. E. D. M'CREA AND A. D. MACDONALD. Univ. Manchester. *Quart. J. Exptl. Physiol.* 19, 161-70(1928).—Adrenaline may produce both inhibitory or augmentor effects on the stomach of the cat and dog. It does not duplicate faradic stimulation of the splanchnic nerves. Pilocarpine, physostigmine and acetylcholine, like the vagus, can be both augmentor and depressor to the stomach. Atropine relaxes and paralyzes the stomach musculature and abolishes all response to nervous stimulation and to drugs. FRANCES KRASNOW

The influence of the thymus on muscle activity. PAUL HELD. Univ. Bern. *Z. Biol.* 88, 76-88(1928).—The subcutaneous or intravenous administration of thymus prepn. Thymaglandol (Hofman-LaRoche) apparently removed muscle fatigue. The effect is obtained on the active muscle also, producing increased activity. Intravenous injection of adrenaline does not produce the same effect. FRANCES KRASNOW

Influence of denervating the thyroid gland on urine volume. A question of secretory innervation of the thyroid gland. ERNST WACHTER. Univ. Bern. *Z. Biol.* 88, 227-38(1928).—Injection of a diuretic caused an increase in urine vol., chloride and carbonate. After denervating the gland there was a marked decrease in output. There is compensation upon administration of thyroxine. FRANCES KRASNOW

The significance of ammonia in nervous respiratory regulation. B. A. SHAZULLO.

Univ. Odessa, Ukraine. *Z. Biol.* 88, 363-8(1929).—Insulin antagonizes the action of atropine or the vagus in the lungs. FRANCES KRASNOW

The activity of the heart during muscarine poisoning. H. BERTHA. Univ. Tübingen und Berlin. *Z. Biol.* 88, 369-76(1929).—Elec. and mech. phenomena cease simultaneously. The irritability remains unchanged for a long time, then loses slowly in quality and finally diminishes rapidly. The duration of the monophasic is always shortened. FRANCES KRASNOW

The effect of nicotine and caffeine on the growth of chickens. RALPH E. CHASE. Univ. Oklahoma. *Am. J. Physiol.* 85, 527-30(1928).—Nicotine in graduated amts. of 0.009 to 0.57 g. per kg. of body wt. daily had no effect on the rate of growth of chicks. Caffeine in daily doses of 0.094 to 0.191 g. per kg. per day markedly retarded growth, but showed no immediate toxic symptoms. J. F. LYMAN

The effects of histamine, formaldehyde and anaphylaxis upon the responses to electrical stimulation of guinea-pig intestinal muscle. I. Agents applied to serous aspect of intestine. GEORGE H. BISHOP AND ARTHUR I. KENDALL. Washington Univ. School. Med., St. Louis. *Am. J. Physiol.* 85, 546-60(1928).—Guinea-pig intestinal muscle responded to elec. stimulation more intensely after treatment on the outside with histamine and less intensely after similar treatment with formalin. Homologous protein acted like histamine on muscle from a sensitized animal. Circular muscle was altered more easily by the chemicals, responded only to shocks above the threshold for the longitudinal, and only after a longer latent period. II. Agents applied to the mucosal aspect of the intestine. A. I. KENDALL AND G. H. BISHOP. *Ibid.* 561-8(1928).—When a strip of gut was irrigated with oxygenated Tyrode's soln., both rhythmicity and reactivity to elec. stimuli were depressed. Reactivity was restored upon stopping the irrigation or upon adding histamine or homologous protein in the case of a gut from a sensitized animal. Formalin added to the Tyrode bath fluid relaxed and depressed the muscle, whether under the influence of histamine or in moderate contraction induced anaphalactically. J. F. LYMAN

The action of colloidal sulfur (sulfosol) on the glucemic titer of the guinea pig during the action of pilocarpine, of ergotamine, and of atropine and vice versa. GIULIO BUCCIARDI. *Biochim. terap. sper.* 15, 411-8(1928); cf. *C. A.* 23, 1176.—The injection of pilocarpine in small or large doses, inactive by themselves, does not modify the hypoglucemic or hyperglucemic action obtained by the previous injection of sulfosol in small or large doses; *vice-versa*, active doses of pilocarpine causing hyperglucemia are not influenced by the S, but instead change the hypoglucemia of the S to hyperglucemia, or intensify an already existing hyperglucemia. Ergotamine does not modify the hypoglucemia or hyperglucemia of S, but if the latter is injected in small doses, it intensifies the ergotamine hypoglucemia, or if injected in large doses, it suppresses, or substitutes the hypoglucemia with hyperglucemia. Atropine does not modify the glucemic action of S; the latter, however, intensifies the hypoglucemia and hyperglucemic action of atropine according to the dose used. These results are of interest in comparing the action of insulin on the glucemic titer, when insulin is injected in combination with pilocarpine, ergotamine and atropine. They may serve as a basis for a new hypothesis regarding the action of S and insulin on the variations obtained in the glucemic titer after these two substances are injected. B.'s conclusion is that the exptl. facts do not support the view that there is an affinity of action between insulin and S especially with regard to the mechanism which regulates the blood sugar of the guinea pig. PETER MASUCCI

Salivary reflex action brought about by repeated injections of morphine. PIETRO DI MATTEI. *Boll. soc. ital. biol. sper.* 3, 810-13(1928).—If dogs are injected with small doses of morphine on successive days, salivation takes place, followed at times by vomiting. This phenomenon often manifests itself at the mere sight of the syringe in the hands of the operator, that is, before injection actually has taken place. M. has been unable to get any evidence of unconditional or absolute reflex action? Two interpretations explaining the phenomenon are given. PETER MASUCCI

Factors which modify the partition of drugs injected in the arteries. L. SCREMIN. *Boll. soc. ital. biol. sper.* 3, 862-3(1928).—Strychnine, caffeine, codeine, pyramidone and narcofine were injected into the carotid artery of rabbits. The minimum active dose of the drugs which acts on the spinal cord was always greater when injected into the carotid artery than when injected into the auricular or jugular veins. Even when twice the minimum active intravenous dose was injected into the carotid, the convulsions were not immediate but only after 1 to 2 mins. When cocaine, which acts both on the cerebral and spinal systems, was injected, the min. intravenous convulsive dose, when introduced into the carotid artery, produced only cerebral reactions. If KCl soln. was injected simultaneously with strychnine nitrate soln. the effect of the strychnine was immediate

whereas if injected alone the action would have been greatly delayed. Urethan had similar properties. From these results the conclusion is drawn that those substances which injure the capillaries in some manner either are able to hinder the fixation and absorption of convulsant drugs or else increase the cellular permeability and thus increase the absorption rate.

PETER MASUCCI

The effect of acridine derivatives on the blood sugar immediately following injection. OTTO J. NIELSEN. Staatshospital in Sønderborg. *Acta Med. Scand.* 70, 12-29(1929); cf. *C. A.* 23, 195, 1685.—Intravenous injections of septacrol have such a slight and inconst. influence upon the blood sugar in persons with normal carbohydrate metabolism and even following an ingestion of carbohydrate that it is denied all together. Likewise, in diabetics, although injection of the acridine derivs. may lower the blood sugar, the effect is totally different from that produced by insulin. S. MORGULIS

Experimental studies of the effect of oral administration of yeast on the carbon and oxidation quotients of urine. PAUL HOFFMANN. Pathol. Inst., Univ. Berlin. *Biochem. Z.* 204, 208-14(1929)—The administration of dry yeast ("Levuriose") increases the N excretion and also to a certain degree the urinary C. The effect is the lowering of the quotients C:N or "Vakat-O_{2:N. The evidence also points to an increased oxidation in the exptl. rabbits. S. MORGULIS}

The effect of adrenaline, sympathol, tyramine, ephetonine and histamine on the gaseous exchange and circulation in man. U. VON EULER AND G. LILJESTRAND. Karolinisches Inst., Stockholm. *Skand. Arch. Physiol.* 55, 1-25(1929).—In a well trained person the effect was investigated of *d*-adrenaline, sympathol, tyramine, ephetonine and histamine on pulse rate, O₂ consumption, systolic and diastolic blood pressure and minute vol. of the heart. The amplitude-frequency product is calcd. from the amplitude of blood pressure divided by the mean pressure and multiplied by the pulse rate, and gives a good measure of the relative blood flow from the heart. Furthermore, the optimum concn. was detd. which increases the reduction rate in the system methylene blue-muscle-phosphate. The many results are best summed up in tabular form, where 0 designates an effect not exceeding 5%, + an increase of 5-10% over the initial value, ++ 10-30% and +++ a change of more than 30%.

Substance	Dose, mg.	Pulse rate	Mean blood-pressure	O ₂ Consumption	Maximum effect Amplitude-frequency product	Minute vol.	Opt. concn. in methylene blue test
<i>l</i> -Adrenaline	0.7	+	+	++	+++	+++	10 ⁻¹²
<i>d</i> -Adrenaline	0.7	+	0	+	+++	+++	10 ⁻¹⁰
Sympathol	50-100	+	+	+	++	++	10 ⁻⁴
Tyramine	20-50	+	+	+	+++	+++	10 ⁻⁶
Ephetonine	50	++	0	+	+++	+++	10 ⁻⁶
Histamine	0.4-0.7	+++	+	+	+++	+++	10 ⁻¹¹

S. MORGULIS

Influence of yohimbine and ergotine on the blood pressure effect of lobeline. PETER WEGER. Kgl. Universitt, Upsala. *Skand. Arch. Physiol.* 55, 104-10(1929).—Neither yohimbine nor ergotamine has any effect on the blood pressure-lowering action of lobeline. S. MORGULIS

The influence of digitalis and strophanthin on the parasympathetic irritability of the intestine. PETER WEGER. Kgl. Universitt, Upsala. *Skand. Arch. Physiol.* 55, 111-30(1929).—The digitalis and strophanthin glucosides reverse to a considerable degree the motor effects produced upon the intestinal preps. by chem. stimuli acting upon the parasympathetic end organs. This alteration of reaction may be due to a change in irritability and contractility of the muscle cells or to an increased parasympathetic irritability. The fact that digitalis has generally a marked affinity for the parasympathetic nervous system and differs from such purely myogenic muscle poisons as BaCl₂ seems to indicate that the mechanism of the effect is through an altered parasympathetic irritability. S. MORGULIS

Relation between chemical constitution and pharmacological action of heart drugs. FERDINAND LEBERMANN. Vesalian Phys.-Chem. Inst., Basel. *Med. Welt* 2, No. 40 (1928).—A general article. WITHROW MORSE

Iodine therapy. P. SCHWILLENBACH. *Med. Welt* 2, No. 40(1928).—General. WITHROW MORSE

The neurotropic properties of relapsing fever spirochetes and the therapy of neuro-spirochosis. H. P. ROSENHOLZ, O. V. OVSYENNIKOVA AND I. A. TREFILOV. Der Medicinol. Inst. und Reichsanst. fr exper. Veterinrmedizin, Moskau. *Centr. Bakt. Parasitenk.*, 1. Abt., Orig., 110, 47-62(1929).—The tendency for *Sp. obermeiri* and

Sp. duttoni to enter and grow in nerve tissue bears no direct relation to their virulence. Arsphenamine preparations will not protect animals with spirochetes in the central nervous system. Such infections in mice with *Sp. obermeiri* form a useful method for studying chemotherapeutic agents and will aid in a search for a "Therapia sterilisans magna."
JOHN T. MYERS

ogenous alcohols. A contribution to the theory of narcosis. R. BEUTNER AND E. HYDEN. Univ. of Louisville, Ky. *J. Pharmacol.* 35, 25-30(1929).—From a mixt. of blood serum and an alkaloidal salt such as pilocarpine-HCl no alkaloid will pass through a parchment membrane. If an alc. be added to the mixt. the alkaloid will diffuse. The amt. of alc. which will just cause diffusion decreases gradually with increasing length of the C chain, until hexyl alc. is reached, with which the effect is maximal. A greater amt. of heptyl or octyl alc. is needed to cause diffusion of alkaloid. These results are contrary to the action of alcs. as narcotics, the narcotic effect increasing continuously with increasing length of C chain.
C. RIEGEL

Susceptibility of adrenalectomized rats to morphine intoxication. EATON M. MACKAY AND LOIS L. MACKAY. Stanford Univ. *J. Pharmacol.* 35, 67-74(1929).—In one group of rats both adrenals were removed, and in a second or control group the adrenals were exposed but not removed. Ten days after the operation adrenalectomized rats were 5 times as susceptible to morphine intoxication as control rats. The mean fatal dose was 0.067 mg. per g. and the min. lethal dose 0.1 mg. per g. For the control rats the M. F. D. was 0.395 mg. per g. and the M. L. D. 0.5 mg. per g. Twenty-five days after the operation adrenalectomized rats were 2.5 times as susceptible as control rats. For the adrenalectomized rats the M. F. D. was 0.15 mg. per g. and for the control animals 0.4 mg. per g.

The mechanism of the increase of the narcotic action of cocaine hydrochloride caused by the addition of alkali. MITSUKUNI NAGASAKI. Chiba Med. Coll. *Chiba J. Med.* 6, 623-32(1928).—A nerve placed in alk. NaCl soln. swells more than in ordinary NaCl soln. Hence N. believes that a physico-chem. change in the nerve itself takes part in the action of alkalis, in increasing the narcotic power of cocaine.
K. SOMEYA

The influence of adrenaline and insulin upon the chlorine content of blood. ISHIN TAMURA. Keijo Med. College. *Chosen J. Med.* 87, 285-94(1928).—In rabbits, adrenaline decreases, and insulin increases, Cl content of the blood. Nervous influences are not concerned.
K. SOMEYA

The influence of choline chloride upon the sodium chloride excretion and the nitrogen metabolism. KAZUO AOKI. Kyoto Imp. Univ. *J. Jap. Loc. Internal Secrecion* 4, 515-27(1928).—Choline chloride, injected into dogs in daily dosage of 10-20 mg. per kg. for 4-5 days, causes a decrease in urinary NaCl and N with no change in their excretory ratio.
K. SOMEYA

The relation between the concentration of anesthetics and the time required for complete anesthetization. KO HAYASHI. Keio Univ. *Keio J. Med.* 8, 365(1928).—H. found that the Wo. Ostwald expression for anesthetic action $1/t = KCP$ (t = the time required for anesthetization, K and P are const. and C = concn. of anesthetics) holds good for various kinds of common anesthetics. H. further observed that the "const." P not only remains const. even when the kinds of the animal used are different, if the same anesthetic is used, but also that the value is the same for the same series of anesthetics. The value of K in the same series of anesthetics increases with the increase of the length of the C chain.
K. SOMEYA

Pharmacological study of amino acid derivatives. IV. The action of various derivatives of phenylalanine. SHINGO GORO. Osaka Med. Coll. *Osaka J. Med.* 27, 2275-310(1928).—The action of amides and esters of each of the isomeric phenylalanine deriva. upon the isolated toad heart and upon blood pressure and respiration of rabbit resembles that of amides and esters of tyrosine; cardiac depression, however, is less. The difference is apparently due to the OH group but this has little influence in amides. V. The action of ethyl esters of various isomeric alanines. *Ibid* 2311-26.—Sympathetic stimulation is stronger in the *l*- than in the *d*-compds. Phenol, 3,4-dihydroxyphenyl, and benzene nuclei increase the cardio-inhibiting power of amino acid esters.
K. SOMEYA

The oligodynamic action of metallic silver. R. WANDERKA, I. DORTZENBACH

AND J. DE LA BARRERA. *Rev. inst. bacteriol. dept. nacl. hig.* 4, 375-84(1926).—Strips of metallic Ag ($2 \times 70 \times 5$ mm.) were placed in doubly distd. H_2O and kept in an atm. of H_2 . After 2 months' contact with the Ag the H_2O exhibited no oligodynamic action when tested against *B. paratyphosus* B (Schottmüller). Exposed under similar conditions in an atm. of CO_2 , the distd. H_2O quickly acquired oligodynamic activity. Conclusions: Under these conditions, it is possible that the Ag changes to the oxide which is slightly sol.

M. H. SOULE

The modes of administration of bismuth salts in antisyphilitic use. M. PRON. *J. pharm. chim.* 7, 380-90(1928).—The advantages of the use of Bi salts in comparison with Hg and org. As compds. are less toxicity, hence larger possible doses, and more lasting activity, unless the mode of application introduces difficulty of the elimination of Bi. The various methods of application are reviewed. The use of aq. or oil solns. of Bi salts permits by intramuscular injection a rapid antisyphilitic action realized thus far only by injection of org. arsenicals. In aq. soln. ammoniacal Bi citrate and Bi cacodylate are well tolerated and are very active forms of administration. Prepn. of both are described. The presence of Hg (1:5) seems to intensify action. Oil soln. of Bi camphocarbonate is useful when aq. solns. are not tolerated.

C. J. WEST

The influence of calcium on glucosuria. ALEXANDRE G. PHOCAS. *Arch. mal. appar. dig. et nutrit.* 17, 1113-5(1927); *Ber. ges. Physiol. exptl. Pharmacol.* 46, 276.—P. administered Ca in several juvenile glucosuric patients and noticed that the amt. of elimination was reduced, for example, from 50-60 g. per day to 12 g. per day. However, Ca is not a specific for diabetes but can influence only glucosuria of certain origins. Ca reduces only those glucosurias which are provoked by Na. The action of Ca is purely antagonistic in the sense of Loeb's idea of colloids. The ionic equil. Ca:Na is especially disturbed in nervous diabetes. The action of the diastatic enzymes and the hormone depends in a large degree upon the ions whose influence on glucolysis is known through the work of Lepine.

R. C. WILLSON

The influence of quinine on the thyroid gland and the suprarenal capsule. S. IGURA. *Folia endocrinol. japon.* 3, 1581-90(1928); *Ber. ges. Physiol. exptl. Pharmacol.* 45, 662.—Histological studies were made on the thyroid gland and suprarenal capsule of rats after injections of quinine. The thyroid gland showed a picture of colloid struma, but it could not be detd. whether this change was produced directly or indirectly. In the anterior lobe of the suprarenal capsule there was found hyperemia and an increase in and an enlargement of the eosinophile cells. Probably compensatory processes are present.

R. C. WILLSON

Comparative studies of different cinchophen preparations and their effect on the elimination of uric acid. The mode of action of cinchophen. TEMMIN KAKU. Univ. Keijo. *Folia pharmacol. japon.* 6, 312-28(1928); *Ber. ges. Physiol. exptl. Pharmacol.* 45, 556.—The preps. studied were: 2-phenylquinoline-4-carboxylic acid (cinchophen), 6-methyl-2-phenylquinoline-4-carboxylic acid (paratophen), 7-methyl-2-phenylquinoline-4-carboxylic acid, 8-methyl-2-phenylquinoline-4-carboxylic acid (isatophen), 6,8-dimethyl-2-phenylquinoline-4-carboxylic acid, 2, *p*-methoxyphenylquinoline-4-carboxylic acid, 6-methyl-2-methoxyphenylquinoline-4-carboxylic acid, 7-methyl-2-methoxyphenylquinoline-4-carboxylic acid, 8-methyl-2-methoxyphenylquinoline-4-carboxylic acid and 6,8-dimethyl-2-methoxyphenylquinoline-4-carboxylic acid. The effect of cinchophen on the elimination of uric acid is strengthened by the use of a $-CH_2O$ group in the phenyl ring. A similar effect results from the use of a $-CH_3$ group in the 8th position in the quinoline group; a $-CH_3$ group in the 7th position has no effect on the elimination, while this factor is decreased by one in the 6th position or by 2 $-CH_3$ groups in the 6th and 8th positions. The uric acid concn. of the blood is increased after the use of cinchophen preps. K. assumes that the cinchophen transports into the circulation the uric acid which is retained in the tissues. After the increase in the concn. of uric acid in the blood there is a secondary increase in the uric acid of the urine. All the cinchophen preps. examd. are antiphlogistic and antipyretic.

R. C. WILLSON

The production of immunity of the rabbit kidney against poisons. I. TSUNEMATSU TSURUMATSU, KIKUO OGII AND HITARO MARUI. *Folia pharmacol. japon.* 6, 329-

56(1928); *Ber. ges. Physiol. exptl. Pharmacol.* 45, 551.—Subcutaneous injection into rabbits of HgCl_2 or cantharidin caused marked kidney injury which manifested itself by pathological changes both in the urine and in the kidney tissue. However, if an animal withstood one such poisoning a second injection of these substances caused no further renal injury. This resistance of the kidney to the poison appears to a considerable degree from 3 to 5 days after disappearance of the nephritic urinary symptoms, and appears completely after 10 to 14 days. When aloin is injected and reinjected the same nephritic changes are evident each time in the urine and kidney tissue; the kidney does not create an immunity against aloin. Only a weak immunity is created against K_2CrO_4 . Repeated chromate injections cause repetition of the urinary changes although the nephritic picture in the tissue of the kidney is less clearly expressed than after the first injection. II. KIKUO OGIU AND EITARO MARUI. *Folia pharmacol. japon.* 6, 379-83 (1928); *Ber. ges. Physiol. exptl. Pharmacol.* 45, 551-2.—In normal rabbits the poisoning by HgCl_2 , K_2CrO_4 or cantharidin caused a very marked decrease in the elimination of phenolsulfonephthalein and a similarly marked increase in the blood residual N. After recovery from the HgCl_2 or cantharidin poisoning the residual N returns to normal, it exceeds normal after K_2CrO_4 poisoning. In immunized rabbits, examd the 2nd day after re-poisoning, the dye elimination after HgCl_2 and cantharidin poisoning was undisturbed and it was only slightly disturbed after K_2CrO_4 poisoning. Residual N after the first two poisons showed a slight increase, and after the K_2CrO_4 there was an increase not quite so intense as in the normal animal, but a rather strong increase nevertheless.

R. C. WILSON

Pharmacological studies of nickel. MATAO YAMAGAMI. Univ. Keijo. *Folia pharmacol. japon.* 6, 389-402(1928); *Ber. ges. Physiol. exptl. Pharmacol.* 45, 420. Y used a weakly acid reacting prepn., sodium oxy-nickel tartrate. After subcutaneous injections of this prepn. frogs and mice do not move freely, but remain quiet, moving only when disturbed. Cramps often appeared. The paresis changes into complete paralysis and the respiratory movements become irregular, then less frequent and finally cease. Intravenous injection of the prepn. lowers the blood pressure of the rabbit, probably because of paralysis of the vasomotor center. On the isolated frog heart dil. solns. irritate and concd. solns. paralyze. The prepn. has only a slight action on the peripheral vessels. On the isolated intestine and uterus of the rabbit, the prepn. in all concns. had a paralyzing effect. Isolated skeletal muscles of the frog were stimulated in dil. solns., paralyzed in concd. ones.

R. C. WILSON

The influence of acids and alkalies on the formation of edema. KAGEMASA KUWAHATA. Univ. Kyoto. *Folia pharmacol. japon.* 6, 440-54(1928); *Ber. ges. Physiol. exptl. Pharmacol.* 46, 142.—The blood vessels of the rabbit ear were perfused with 0.01 N HCl, chromic, acetic and lactic acids and 0.01 N NaOH and KOH. The development of the edema, which also occurs when Ringer soln. is used, is accelerated to a marked degree, in spite of the reduction of the vol. of flow which appears to be due to injuries to the vascular walls caused by the agents used.

R. C. WILSON

The vascular action of cholic acid. KANSHO RYO. Univ. Kyoto. *Folia pharmacol. japon.* 7, 48-58(1928); *Ber. ges. Physiol. exptl. Pharmacol.* 46, 278.—The femoral vessels of the frog reacted to weak concns. of cholic acid by contracting, while somewhat stronger solns. produced dilatation and contraction and very strong concns. affected principally contraction. When the vessels had been pretreated with adrenaline, cholic acid produced a strongly expressed dilatation. Cholic acid usually caused the vessels in the ear of the rabbit to dilate while very strong concns. produced a temporary dilatation and a subsequent strong contraction. The portal vein of the rabbit showed only a very slight dilation when treated with cholic acid. Cholic acid stimulates both the dilators and constrictors.

R. C. WILSON

The influence of different anions of the ammonium salts on the sugar in the blood and urine. H. MASAMUNE. Univ. Fukuoka. *Fukuoka-Ikwadaigaku-Zasshi* 20, 511-31(1927); *Ber. ges. Physiol. exptl. Pharmacol.* 46, 89; cf. following abstract. After subcutaneous injections of NH_4 salts into the rabbit, the blood sugar increased very sharply after the phosphate, less after the sulfate and chloride and least after the acetate. The anion has no influence on the duration of the hyperglucemia; a prolonged duration was noted only after the phosphate. Section of the splanchnic nerve suppressed the hyperglucemia produced by acetate, chloride and sulfate, while that following phosphate was only weakened.

R. C. W.

Which components play a role in the blood sugar increase following the application of ammonium salts? H. MASAMUNE. *Fukuoka-Ikwadaigaku-Zasshi* 20, 726-45 (1927); *Ber. ges. Physiol. exptl. Pharmacol.* 45, 512.— NH_4Cl lowers the blood alkali; acidosis increases the blood sugar. M. studied the variation of the blood CO_2 after the

application of different NH_4 salts and found that NH_4 acetate in small doses which do not reduce the alkali reserve can in contrast to NH_4Cl increase the blood sugar. This study was pursued further with Na acetate to det. if the AcOH ion has a sp. action on the blood sugar increase and led to a positive result. Urea, the intermediate product of NH_3 , has no effect whatever on the blood sugar, when the dosage has a N content equal quantitatively to that of the dosage of the NH_4 salts. The blood NH_3 increase after subcutaneous injection of NH_4 salts is detectable for a proportionately longer time. After the subcutaneous injection of NH_4OH the blood sugar rose, just as it did after the use of NH_4 acetate, NH_4Cl and $(\text{NH}_4)_2\text{SO}_4$, but this change did not appear in bilateral splanchnicotomized animals. Summarily, the blood sugar increase after the injection of some NH_4 salts can be attributed to the NH_4 ions only in such salts as NH_4 acetate, which has a very weak action on the blood alkali reserve.

R. C. WILLSON

The intra-spinal use of lobeline. F. HAZAMA. *Japan. J. Obstet. and Gynecol.* 10, 38-44(1927); *Ber. ges. Physiol. expll. Pharmacol.* 46, 284.—In normal rabbits there is no difference between the intravenous and the intraspinal action of lobeline; the no. and vol. of the respirations are decreased. In a 2100 g. rabbit from which 48-cc. blood had been withdrawn the action continued for 35 mins; the respiratory vol. was larger after the injection. In animals which had received 0.03 g. morphine intravenously, the respiratory vol. was increased even 90 mins. later (820 against 660). The respiratory vol. is less 21 mins. after the intravenous injection than it was before the injection. In all the expts. the injected dose was 0.2 cc. of 0.03% soln. of lobeline. Effects of intra-spinal injections persist longer.

R. C. WILLSON

The elimination of injected polonium. JEANNE S. LATTES AND A. LACASSAGNE. *J. radiol. et électrol.* 12, 16-9(1928); *Ber. ges. Physiol. expll. Pharmacol.* 45, 420.—After subcutaneous or intraperitoneal injection Po is eliminated by rabbits through the kidneys and intestines, is in the same order of magnitude, beginning at about the same time after the injection and gradually becoming smaller. Traces were found even several days later. Only about 10% of the injected 100-500 e. s. u. was recovered. The remainder could not be found in the bodies of the animals so it is assumed that it was eliminated in other ways, particularly by the skin and lungs. In further studies Po was injected with other metals as Fe, Bi and Hg; the resorption and elimination were retarded.

R. C. W.

Studies of auditory disturbances due to nicotine. KAN-ICHI FUKUYE. *Med. Akad., Kyoto. Kyoto-Ikadaigaku-Zasshi* 1, 953-960(1927); *Ber. ges. Physiol. expll. Pharmacol.* 45, 568.—Subcutaneous and intravenous injections of nicotine into rabbits produced atrophy of the organ of Corti, macula and crista acoustica and degenerate atrophy of the cochlear and vestibular nerves and of the spiral ganglion.

R. C. WILLSON

The influence of some stimulating poisons on the action of tetrodotoxin on the skeletal muscle. RYUZO KATAGI. *Univ. Okayama. Okayama-Igakkai-Zasshi* 39, 1869-80(1927); *Ber. ges. Physiol. expll. Pharmacol.* 45, 576.—Tetrodotoxin is a toxin which was isolated by Tawara from the ovaries of the toxic Japanese fish of the tetrodon class. This toxin has a curare-like action on the skeletal muscle and paralyzes the respiratory and vascular centers. On isolated neuro-muscular preps. the action of tetrodotoxin was antagonistic to that of guanidine, strychnine, caffeine, camphor, strophanthin and adrenaline, although the antagonism of the different substances is different: adrenaline stimulates the motor nerve-endings; caffeine, camphor and strychnine act chiefly on the muscle itself while guanidine and strophanthin probably stimulate both elements. Tetrodotoxin is active even in a concn. of 0.00005%. In intoxication with strong concns. of it, only caffeine, camphor and strophanthin are antagonistic.

R. C. WILLSON

The action of ethyl alcohol on dehydrating processes and the consumption of oxygen by muscular tissue. G. DI MACCO AND P. FORMICOLA. *Rivista patol. sper.* 3, 44-51(1928); *Ber. ges. Physiol. expll. Pharmacol.* 45, 618.—Expts. with frogs showed that EtOH in concns. of 2-4% changes the dehydrating process and the consumption of O by the tissue. The changes depend upon the dose. Small doses first increase and then decrease the dehydration, while larger doses effect a fleeting reduction which is followed by an increase. Small doses are temporarily inhibitive to oxidation; larger doses are temporarily activating. The O consumption of the organism is increased more by small doses of 2% alc. than it is by large ones. In alc. concns. which are not harmful to cellular operation, one part of the increased consumption of O is used for the combustion of alc. while another part defrays an increase of the cellular metabolism. If the alc. concn. exceeds a certain limit, there probably occur changes in the phys. and chem. equilibrium in the cell and the surrounding medium, which inhibit the O consumption.

R. C. WILLSON

The action of candiolin and levulose on the isolated heart. J. BIANCO. Univ. Rosario. *Rev. soc. Argentina biol.* 3, 611-6(1927); *Ber. ges. Physiol. exptl. Pharmacol.* 45, 382; cf. *C. A.* 22, 822.—Candiolin exerts a favorable influence on the isolated heart when its Ca content is equalized by K. The favorable effect depends upon the hydrocarbon portion of the mol. Candiolin, however, shows no advantage over glucose. In washing the isolated heart, it is suggested that Ringer soln. with levulose be used, since this is more active than Locke soln. with glucose. R. C. WILLSON

The mechanism of the secretion of saliva after atropine. V. KRIJLOV. *Russ. fisiol. zhurnal* 9, 156-7(1926); *Ber. ges. Physiol. exptl. Pharmacol.* 45, 567.—When atropine is introduced into the conjunctival sac of the cat, there follows a copious secretion of saliva. It was observed that the cats moved their tongues as if to eliminate the saliva. K. assumed that the poison had spread from the conjunctival sac into the mouth. Instillation of methylene blue into the eye colored the tongue. Other alkaloids, as cocaine, etc., when introduced into the eye also produced a secretion of saliva. From dogs with chronic salivary fistulas it was learned that the mucous membrane of the mouth is very sensitive to alkaloids (morphine, atropine and cocaine), even very weak solns. causing a copious secretion of saliva. R. C. WILLSON

The action of pyridine and its alkyl derivative on the ciliated epithelium. Experiment in tissue culture. T. UMEDA. Univ. Kyoto. *Acta dermatol.* 11, 273-7(1928); *Ber. ges. Physiol. exptl. Pharmacol.* 46, 356.—The test material was small pieces of ciliated epithelium of the frog throat, the ciliary movement of which was maintained in the tissue culture in a plasma medium. Both pyridine and its alkyl deriv. exert an accelerating influence on the ciliary movement. R. C. WILLSON

Pharmacological evaluation of digitalis preparations (Focke) 17.

R. A. GORTNER

Oöplasmic intermicellar fluid. K. BIALASZEWICZ. *Acta Biol. Exptl.*, Warsaw 1, No. 11, 1-52(1928).—The K contents of the ash of eggs of birds, amphibia, fish, crustacea, mollusks, echinoderms and annelids are comparatively const., while the Na, Ca and Mg contents, which are considerably lower, are more variable. From 20 to 63% of the vol. of the oöplasm is taken up by org. colloidal substances. The greater part of the alkali metals and Cl present is to be found in the intermicellar fluid in a dialyzable form, while the alk. earth metals and H_2PO_4 are for the greater part adsorbed reversibly on the dispersed phase. The mineral content of the intermicellar fluid is fairly const. for the above-named species, 10 parts of Na, and 7 each of Ca and Mg being present for every 100 parts of K. B. C. A.

Mercurochrome as a fungicidal agent in the growth of amphibian embryos. S. R. DETWEILER AND G. E. MCKENNON. *Anal. Record* 41, 205-11(1929).—Mercurochrome in concns. from 1:500,000 to 1:1,000,000 was used successfully as a fungicidal agent in the growth of *Amblystoma* embryos. These concns. in continuous treatment were toxic to embryos under, but not to embryos over, two weeks old. BYRON C. BRUNSTETTER

Some digestive enzymes in the crop juice of native Pulmonata. Preliminary paper. ERICH GRAETZ. Univ. Berlin. *Z. physiol. Chem.* 180, 305-7(1929). Five species of snails, including herbivorous, omnivorous and fungivorous types, were examined with respect to enzymes present in their gastric juice. The feeding habits of the animals appear to have no influence on the concn. of enzymes which digest Witte peptone at the optimum pH of 7.6. Erepsin is present as shown by hydrolysis of alanylglycine at a pH optimum of 7.3, and probably a protease since casein and fibrin are also attacked. A lipase is present which hydrolyzes the lower neutral fats more readily than the higher fats or the lower esters. Its optimum pH with acetate buffer is 5.7; with glycine buffer 9. In its natural medium the lipase is more stable than that of vertebrates, and retains its activity for weeks. Quinine and NaF inhibit tributyrin cleavage. Carbohydrates whose cleavage was demonstrated polarimetrically are sucrose, maltose, raffinose, arabin and sol. amylose, but undissolved starch grains are not attacked. A. W. DOX

Growth rates of brook trout reared upon purified rations, upon dry skim milk diets, and feed combinations of cereal grains. C. M. McCAY, W. E. DILEY AND M. F. CROWELL. Animal Nutrition Lab. Cornell Univ. and Conn. State Hatchery, Burlington. *J. Nutrition* 1, 233-46(1929); cf. *C. A.* 22, 1771-1772.—Expts. attempting to define the fundamental nutritional requirements of the lower vertebrates are continued with brook trout. Exptl. groups were started for periods exceeding 20 weeks by feeding purified rations contg. a low level of protein and by feeding a limited amt. of a protein food, as raw liver. Alternating periods of stunting and growing indicate that

there is a tendency toward compensation during the growing period which makes the rate tend to exceed the normal optimum. The factor in raw meat which seems to be the most active agent in stimulating the growth of trout is not extd. by EtOH or Et₂O. It is not identical with any of the known vitamins. Synthetic purified rations of starch, casein, and salt mixt. with vitamin supplements will permit a limited growth in trout if the protein level exceeds 10%. Trout are equally stunted when the protein level is 10% whether the ration contains 3 or 8% mineral matter. Trout stunted upon low-protein diets live twice as long as those that are allowed to grow upon similar synthetic rations with a higher protein level. This indicates that their bodies contain a store of some substance that is essential for life but is consumed in growth. Expts. with various traces of mineral supplements to skim milk indicate that its failure is not due to deficiencies in Zn, Cu, Fe or I. Raw liver is a much more effective supplement for a milk diet than raw spleen. Dried buttermilk is slightly better as a trout feed than dry skim milk when each is employed singly. Trout are able to use corn gluten, flour and peanut meal for growth and maintenance. As a converter of matter, the trout compares very favorably with the most efficient of the higher mammals and is possibly somewhat superior.

C. R. F.

The urine of the goosfish (*Lophius piscatorius*): its nitrogenous constituents with special reference to the presence in it of trimethylamine oxide. ARTHUR GROLLMAN. Johns Hopkins Univ. *J. Biol. Chem.* 81, 267-78(1929).—A study was made of the urinary constituents of the goosfish. The chief nitrogenous constituents of this urine were found to be creatine, creatinine and amino acids. NH₃, urea and uric acid were present only in small amts. The remainder of the urinary N was made up chiefly of (CH₃)₃N.O which was isolated and identified. Specimens of urine obtained from the fish freshly caught in the Atlantic were found to contain much more N and much less inorg. salts than the analyses reported previously by other observers. A. G.

The composition of the body fluids of elasmobranchs. HOMER W. SMITH. Univ. of Va. and Mt. Desert Island Biol. Lab., Me. *J. Biol. Chem.* 81, 407-19(1929).—Analyses were carried out of the various constituents of the body fluids of *Raja stabuliformis* and *R. diaphenes*, *Carcharias littoralis* and *Mustelus canis*. The pericardial and perivisceral cavities of these fishes contain fluid which is extremely acid and differs markedly from the blood plasma in its compn. The cerebrospinal fluid approximates a protein-free ultrafiltrate from the plasma. Urea is approx. equally distributed per kg. of H₂O between the plasma and tissues but may occur in very different concns. in the various body fluids. The secretory functions of the pericardial and peritoneal membranes are emphasized.

ARTHUR GROLLMAN

Studies on blood cell metabolism. III. The effect of methylene blue on the oxygen consumption of the eggs of the sea urchin and starfish. The mechanism of the action of methylene blue on living cells. E. S. GUZMAN BARRON. Johns Hopkins Univ. *J. Biol. Chem.* 81, 445-57(1929); cf. *C. A.* 22, 4603.—Methylene blue produces an increased O consumption when added to sea urchin or starfish eggs. Narcotics inhibited this effect but CN⁻ was without effect. The increase in O consumption was proportional to the level of anaerobic metabolism. The oxidative action of methylene blue is considered as one of oxidative dehydrogenation, the dye playing a catalytic role because of its reversibility and spontaneous oxidizability by mol. O without a catalyst.

ARTHUR GROLLMAN

Changes in the nuclear-plasmic ratio of vertebrate poikilotherms during hunger. ANTHONY DMOCHOWSKI. Warsaw Univ. *Biochem. J.* 22, 1548-54(1928).—The nuclear-plasmic ratio (N.P.) was practically const. for frogs; in the case of axolotls it rose to 15% after 5 months of hunger and fell to 15% below normal after 11 months of hunger. The N.P. of trout after 80 days' hunger rose by 30% for fry and 49% for 2-year olds. Yearling trout exhibited an increase of about 50% after 90 days of hunger.

BENJAMIN HARROW

The action of minute thyroxine doses on the respiration of non-vertebrate. B. ROMKIS AND J. WÖR. Anatom. Anstalt, München. *Naturwissenschaften* 17, 104-5 (1929).—V. Dobkiewicz (*Arch. Entw. mechanik* 114, 458(1928)) has shown that a prolonged diet of thyroid has no influence on the morphology of insects. The effect of thyroid material on the respiration of non-vertebrates was studied. Winter pupae of *Papilio podalirius* (800 to 1000 mg. wt.) in a 12° thermostat were injected with 50 or 25 cu. mm. thyroxine soln. of varying concn. Their respiration was observed by Krogh's microrespirometer and by CO₂ absorption. Injection of 50 cu. mm. of a soln. of 1 mg. synthetic thyroxine dissolved with a trace NaOH in 500 cu. mm. 1% NaCl soln. (isotonic) as well as injection of 25 cu. mm. of a 1:250 thyroxine soln. gave during 8 to 14 days an increased O consumption of 80 to 80%. Without NaCl 25 cu. mm. 1:1000 thyroxine

soln. also gave a 50% rise. For more dil. solns. the action becomes quite different. For 1:10⁴ diln. down to 1:10⁶ no action results for 4 or 5 days; then, however, the O consumption increases for 1 or 2 days to a 10-, sometimes 30- or 40-fold value, subsequently rapidly dropping to normal or subnormal. Between 1:10³ and 1:10⁴ dilns. the initial period becomes 7 to 9 days but the temporary respiration peak is as high. The results are evidence of the remarkable action of hormones specially in minute doses. No resultant morphological change (e. g. shortening of metamorphosis period) was observed.

B. J. C. VAN DER HOEVEN

Relations of the liver to asphyxial hyperglucemia in fishes. W. W. SIMPSON. Pacific Biol. Sta., Nanaimo, B. C. *Quart. J. Exptl. Physiol.* 19, 197-9(1928).—The normal blood sugar of ling cod is of the same order as other teleosts. A delay occurs between asphyxiation and onset of hyperglucemia. Asphyxia following complete leparectomy in fish does not cause hyperglucemia. In "mock leparectomy" asphyxia causes high blood sugar.

JAROSLAV KUČERA

Determination of phosphoric acid in foodstuffs. W. WHARTMANN. *Z. Unter such. Lebensm.* 55, 610-13(1928).—For the detn., the following solns. are prepd: (1) 210 g. NH₄ molybdate in 300 cc. of H₂O and 400 cc. of 10% NH₄OH soln., (2) HNO₃ (d. 1.2), (3) 1% soln. of KNO₃ solns. (1) and (2) are mixed shortly before use in the proportion of 1:2; 75 cc. of this mixt. is added to the phosphate soln. in the cold, 0.5 g. of (NH₄)₂SO₄ having been previously dissolved in the latter. The mixt. is stirred with a glass rod without touching the sides of the beaker until pptn occurs. After 4 hrs. the filtration is carried out on a close-grained BaSO₄ filter paper, and the ppt. is washed with 1% KNO₃ soln. until 10 cc. of the wash H₂O is neutralized to methyl orange by 1-2 drops of 0.1 N soda. The filter and ppt. are placed in a beaker, covered with a 1% KNO₃ soln.; the ppt. is dissolved by gradual addn of carbonate free N soda. The excess of soda is detd. by titration with N H₂SO₄. Satisfactory results were obtained for a standard phosphate soln., and detns. of H₃PO₄ in wine and of EtOH sol. H₃PO₄ in dried eggs gave results in agreement with those obtained by the Mg₃P₂O₇ method.

B. C. A.

The determination of moisture in wheat and flour. A study of "moisture testing" in water ovens and electric ovens. E. A. FISHER AND C. R. JONES. Research Assoc. of British Flour Millers, St. Albans. *J. Agr. Sci.* 18, 649-70(1928).—The nature of the problem of moisture detns. on materials such as flour and wheat is discussed. The electrically heated air oven is the most convenient and suitable instrument for routine purposes; comparative results show that it allows of far more reliable work than the water oven. Detns. of apparent moisture content were made on a sample of wheat flour in elec. ovens at temps. ranging from 90° to 140° and for periods of heating of 1-14 hrs. At several temps., variation in time of heating over a considerable range does not affect the values obtained. With ground wheat, the results differed from those with flour in that over the ranges studied at all temps. the figures obtained increased steadily but at diminishing rates with increasing time of heating up to about 12 hrs. The effects of the position of containers in the type of elec. oven used and of the size of sample are shown to be negligible. Ca carbide is shown to be as efficient a desiccating agent as H₂SO₄ and more suitable for routine work in mills.

P. R. DAWSON

The baking strength of Arizona Early Baart flour. MARGARET CAMMACK SMITH. Ariz. Agr. Expt. Sta. Tucson, *Tech. Bull.* 23, 549-607(1928); cf. C. A. 23, 446. Phys. and chem. tests place Early Baart wheat as a better class soft or semi-hard wheat. The crude protein content was 9.84% and the gliadin-glutenin ratio 0.402. The buffer action was high and a fair amt. of diastatic action was found. A moderate fermentation period gave higher loaf vols. than either short 1-period fermentations or long-continued periods. Four % of yeast and 6% of sugar yielded a max. loaf vol increase.

The sponge method gave a superior quality loaf as compared with the straight-dough procedure. The addn. of the sugar to the flour before sponging gave loaves of poor vol., color, texture and flavor probably due to the exhaustion of the yeast food before the last stages of the fermentation process. Mineral-salt mixts. (concn. 0.32%), when added to the basic formula, stimulated yeast activity and caused a rapid increase in H-ion concn. as was evidenced by a lower p_H value of the baked product. High-speed mixing (152 r. p. m.) mechanically modified the gluten of the flour, thereby aiding the action of the H ions in attenuation of the gluten network. A yield of 293 loaves of 1 lb. each of high-quality bread was obtained from 1 bbl. of flour. C. R. F.

Improving flour with gaseous chlorine. M. NEUMANN AND H. KALMIUS. *Russ. intern. Agr.* 1926, 444; *La chim.* 3, 141(1927).—In Golo's bleaching process gaseous Cl_2 is used together with 0.5–1.5% $NOCl$ and a certain quantity of air. The flour is agitated continually in a mixer; it absorbs with avidity the gas in the concn. 0.015–0.02%, remaining completely odorless, with no HCl or HNO_2 formation. Under the influence of the gas, the swelling capacity of the colloidal substances (albumin) increases, and these absorb more water and produce a more abundant tenaceous and softer paste. The action is caused by an increase in the acidity of the flour. The soly. of the N products also increases. When the two factors increase more than normally, which happens principally with soft grain, the action of the gas can be nullified. This also takes place by treating too long. The gas has no action on the preservability of the flour or on the activity of the enzymes. R. SANSONE

The microscopic examination of starches and flours. W. GARNER. *Ind. Chemist* 5, 119–20(1929). E. H.

Seasonal and monthly variations in the average composition of milk. R. L. ANDREW. Dominion Lab., Wellington, N. Z. *New Zealand J. Sci. Tech.* 10, 229–35(1928).—In Wellington, N. Z., the winter and summer milk is of medium quality. Autumn milk is the richest and spring milk is the poorest. These periods do not correspond with similar periods in England probably because of differences in climate, feeding methods, etc. The yearly averages for fat and solids not fat are:

Year	Fat	Solids not fat	Year	Fat	Solids not fat
1917	4.05%	9.06%	1922	4.21%	9.03%
1918	4.06%	9.04%	1923	4.12%	9.04%
1919	4.06%	8.97%	1924	4.21%	9.02%
1920	4.13%	9.03%	1925	4.22%	9.07%
1921	4.15%	8.99%	1926	4.27%	8.96%

RUSSELL C. ERB

Experiences with physical methods in milk analysis. J. KRENN. *Z. angew. Chem.* 42, 202–4(1929).—A critical discussion of several well-known phys. methods used in milk analysis. J. C. JURRGENS

Physical-chemical studies of cow milk and its preparations. MASAMI NAKAYAMA. Med. Akad., Kyoto. II. *Kyoto-Ikadaigaku-Zasshi* 2, 923–30(1928); *Ber. ges. Physiol. expil. Pharmacol.* 46, 353; cf. C. A. 23, 1963.—At the optimal p_H the separation of casein in cow milk and its manuf. preps. was not influenced by the temp. or by the duration of time. The isoelectric point of the casein at 40° was as follows: milk casein, p_H 4.37–3.82; casein from milk powder ("Kintaro," "dry milk," "Lactogen" and "Derigold"), p_H 4.16–3.32; casein from Nestle's milk food and the condensed milks (malted milk, "Eagle Brand" and "Bear Brand"), p_H 4.37–4.07. R. C. WILLSON

The buffer action of milk. M. COMEL. *Boll. soc. ital. biol. sper.* 3, 908–11(1928).—Filtered goat milk was added to $M/30 NaH_2PO_4$ and Na_2HPO_4 and to $M/60 Na_3PO_4$ in the proportions of 1:1, 1:2 and 1:4. The p_H of the mixts. was detd. potentiometrically. The results are given in tabular form and show (a) the p_H of the phosphate soln. alone, (b) the p_H of the mixt. as detd. potentiometrically, (c) the p_H of the mixt. calcd by averaging the p_H of the phosphate soln. and the milk, and (d) the difference between (c) and (d). Milk had a decided buffering action, especially marked in the extreme acid and alkaline range of the phosphate solns. The buffer action of milk plasma. *Ibid* 912–15.—By plotting (y) the p_H of the mixt. of phosphate soln. and milk against (x) the p_H of the phosphate soln. alone, the curve showed two points of inflection. To investigate the cause of this, the milk was centrifuged at 6000 r. p. m., the fat separated, and the skimmed milk filtered. The plasma was mixed with the phosphate solns. as described above and the p_H detd. The results were similar to those observed with whole milk except that they differed quantitatively. The buffer action of the whole milk was slightly greater. The buffer action of milk serum. *Ibid* 915–8.—In order to det. what part of the buffer action of milk is due to ionized proteins, milk was coagu-

lated by means of rennet; the serum was decanted, centrifuged at 6000 r. p. m. and filtered. Varying proportions of phosphate solns. were added to the serum and the p_H was detd. By comparing these results with those obtained with whole milk and skimmed milk, it was clear that the buffer action of milk serum was analogous to that of whole and skimmed milk. The p_H was shifted quantitatively, but not qualitatively, so that the curves obtained by plotting (y) against (x) were similar in shape. The buffer action of milk is, therefore, due principally to the presence or formation of complex acid salts, proteinates, or salts of protein acids, and to a lesser degree to the presence of proteins as such.

PETER MASUCCI

Calculation of dry weight of milk. R. SAAR. *Z. Untersuch. Lebensm.* 55, 573-7 (1928).—From Fleischmann's formula (*C. A.* 8, 3827) $t = 1.2f + 2.665 [100 - (100 - 0.25d + 0.26 + 0.2f + c)]$, in which t is the fat-free dry wt. %, d the lactodensimeter reading, and c a value depending on the sp. gr. of the milk. For $d = 21.7-23.7$, $c = -0.02\%$; for $d = 23.8-26.5$, $c = -0.01\%$; for $d = 26.6-38.4$, $c = 0$. The Herz formula $r = 0.25d + 0.2f + 0.26$ gives correct results except for highly dild. milk, for which the small correction c should be applied.

B. C. A.

Detection of the degree of heat in (pasteurized) milk. P. WEINSTEIN. Chem. Untersuchungsamt Bochum. *Z. Untersuch. Lebensm.* 56, 457-67 (1928).—Milk when heated to 85° for 1 min. gives a neg. Rothenfusser reaction for oxidase. At 70 for 30 mins., the oxidase reaction is pos. but the Schardinger aldehyde-reductase test is neg., i. e., the color does not appear within 22 mins. Normally, milk pasteurized by the holding method gives a pos. oxidase reaction and a low catalase value, the color appearing only after 10-11 mins. and producing only 8-10 cc. of O_2 per 100 cc. of milk. In sufficiently heated milk gives a catalase value above 10 and gives a pos. reaction for amylase. Milk heated to only $54-5^\circ$ gives a strong amylase value of 0.1-0.5 and a catalase value of from 30 to 50. Raw milk reacts strongly to both amylase and cat.

C. R. F.

The commercial application of *Lactobacillus acidophilus* milk. E. L. REICHAERT AND H. P. DAVIS. Neb. Agr. Expt. Sta., *Bull.* 228, 1-19 (1928).—Methods are given for prepg., storing and handling together with a summary of the available information on *acidophilus* milk.

C. R. F.

Changes produced in milk under the influence of change from dry feeding to pasture and from additions of calcium salts. N. PELEKHOV. *Zapiski Belorussian Gosudarstv. Akad. Sel'skogo Khosyaistva* (Memoirs Belorussian State Acad. Agr., No. 1, 1-10 (1926).—Expts. have shown that a sharp change in the feeding of cow from a dry ration to pasture increases the percent of fat, protein and ash. However, this increase is temporary and is apparent until the animal loses some of its excessive weight. The catalase content of the milk suffers a sharp decline, which is due to the acidifying processes which take place when the cow is turned out on pasture. Addition of Ca to the feed of the cows in the form of phosphate increases the Ca content of the milk. No such effects were noted when $CaCO_3$ was added.

J. S. J. D.

Influence of ultra-violet ray upon the milking cow. KENZO IGUCHI AND K. YARO MITAMURA. *J. Faculty Agr. Hokkaido Imp. Univ.* 24, Pt. 2, 39-60 (1928).—Expts. were carried on in 15-day periods, 6 days' prepn. and 9 days' expt. Ultra violet ray irradiation upon the cow's udder (both back and sides) at a distance of 25 cm. from the source of light and for 30 mins. a day produced an increase of 4.77% milk and butter fat. Irradiation upon the cow's food showed an increase of 2.92% of the total milk wt. and 4.24% of the total fat wt. in the av. of 2 cows. There was no change in the CaO and P_2O_5 of the milk drawn from irradiated udders.

R. C. E.

Detection of egg yolk in margarine. J. ANGERHAUSEN AND G. SCHULZE. Hygien. Staatsinst. Hamburg. *Pharm. Zentralhalle* 70, 183-7 (1929).—A comprehensive discussion is given of the difficulties incident to the detection of egg yolk in margarine leading to the conclusion that neg. results obtained via Fendler do not necessarily prove the absence of actually added constituent as claimed by the manufacturer, but may indicate rather that the egg yolk employed had in its prior treatment been rendered more or less completely insol. in 2% $NaCl$ soln. This can be detd. only after consultation with the manufacturer.

W. O. E.

The p_H of the white as an important factor influencing the keeping quality of hen eggs. P. F. SHARP. *Science* 69, 278-80 (1929).—Freshly laid hen eggs contg. very few microorganisms keep very well if the p_H of the white is maintained about 7.6, the normal figure. Stored eggs lose CO_2 ; this loss causes watery whites and a shift of the p_H from 7.6 to about 9.7. The addition of 1% CO_2 to the air in warehouses is not dan-

gerous to workmen, adds but little to the cost of the eggs and greatly assists in maintaining the normal appearance of the white.

G. H. W. LUCAS
Studies in cereal chemistry. I. The present position of cereal chemistry and its relation to chemical industry. T. H. FAIRBROTHER. *Ind. Chemist* 5, 91-2(1929).

E. H.
The question of the improvement of the manufacture of edible oils and fats. K. LÖFFL. *Chem.-Ztg.* 53, 125-6(1929).—Nutritional investigations have made new demands on the mfg. methods for edible fats and oils. These demands include: a consideration of the vitamin content of the finished product; the vitamin loss during the processes of extn. and refining; and the physiologically correct synthesis of artificial fats such as margarine, etc. Refining with NaOH, for instance, is a method that destroys a large percent of the vitamin content of fats.

RUSSELL C. ERB
Fruit juices and fruit beverages. JOHN H. IRISH. Agr. Expt. Sta., Berkeley, Cal. *Fruit Products J. and Am. Vinegar Ind.* 7, No. 11, 10-12; No. 12, 17-19 and 21; 8, No. 2, 15-17; No. 3, 12-14; No. 4, 12-14(1928); 8, No. 7, 13-15 and 19(1929).—In this series of papers I. discusses: general principles; equipment; hints on filtering; storage containers; bottle pasteurizers; filling machines; securing a distinctive and pleasing flavor in grape juice; crushing and stemming; extn. of colors; the most efficient methods of bottling, pasteurizing, canning, removing cream of tartar, and carbonating grape juice; pasteurizing in barrels and preserving with H_2SO_4 ; treatment of apple juice for bottling and canning; preserving loganberry, pomegranate and citrus juices; pasteurization vs. cold storage or the use of preservatives—I. recommends pasteurization; beverages from fresh fruits; and spoilage—the most serious type is not that caused by microorganisms but by chem. and enzymic action. Methods for overcoming this problem are discussed.

J. A. KENNEDY
The fluorescence of honey in ultra-violet light. G. ORBAN AND J. STITZ. *Inst. Kg. Ungarischen Elisabeth, Univ. Pécs. Z. Untersuch. Lebensm.* 56, 467-71(1928).—All of the samples investigated luminesced in ultra-violet light. The intensity of the luminescence depends upon the origin or derivation of the sample. After cooling to below 30°, samples of honey, which had been heated to 60°, 80° and 100°, had the same luminescence as before heating. The test is of doubtful application in the routine examn. of honeys.

C. R. F.
Dextrins of honey and artificial honey. J. FIEBE AND W. KORDATZKI. *Z. Untersuch. Lebensm.* 55, 602-8(1928).—Dextrins were obtained from various natural and artificial honeys by pptg. proteins, mucins and other substances by MeOH and then pptg. the dextrins by adding EtOH and Et_2O . All gave Jolles' diphenylamine test for levulose (C. A. 4, 785, 1185). Even after repeated pptn. and prolonged digestion with abs. EtOH to remove any traces of sucrose and levulose, a positive reaction for levulose was obtained. It is concluded that both in natural and artificial honey, dextrins contg. levulose mols. occur. To det. approx. the amt. of the levulose fraction a 1% dextrin soln. is heated with 2/5 of its vol. of 5 N HCl for 2 1/2 hrs. on the boiling H_2O bath. The dextrose is unchanged but the levulose forms among other substances hydroxymethylfurfuraldehyde. The difference in the I value detd. before and after extn. of the soln. with EtOAc is an approx. measure of the levulose originally present. Comparison of the results with those obtained for synthetic mixts. of dextrose and levulose indicate the presence of 20-30% of levulose mols. in the dextrins of honey and artificial honey.

Simplified sugar and sirup calculations for preserves and canners. C. R. FELLERS AND M. J. MACK. *Mass. Agr. Coll., Amherst, Mass. Fruit Products J. and Am. Vinegar Ind.* 8, No. 7, 16-19(1929).

J. A. KENNEDY
Cacao beans and cacao products. V. Pigments of cacao beans and cacao products. Ash content of cocoa paste. H. FINCKE. *Z. Untersuch. Lebensm.* 55, 559-68(1928).—The 2 pigments of cacao beans are designated cacao-red and cacao-brown. Cacao-red is sol. in EtOH, is bright red in acid soln., violet in neutral soln. and green or greenish-blue in alk. soln. Cacao-brown gives cacao its characteristic color; it is only slightly sol. in EtOH but readily sol. in alk. aq. solns. Both are tannin substances. Cacao-red occurs in variable amts. in the fresh seeds, in com. fermented beans and in the finished cacao products. Cacao-brown does not occur in fresh seeds but is gradually produced from a colorless parent substance in the several processes of fermentation, roasting and grinding. Cacao-red is also transformed into cacao-brown in the fermentation process and in the prepn. of cacao powder with the addn. of alkali. Cacao-red is produced in the living plant, probably from the same parent substances as cacao-brown and its parent substance by the action of alc. HCl. Detns. on cacao material from several sources show an ash content of the dried paste of 2-4.5%. B. C. A.

Nutritional value of extracted cattle feed. G. B. VAN KAMPEN. *Chem. Weekblad* 26, 98-101(1929).—Soy-bean meal extd. with trichloroethylene caused severe sickness among cattle. It was found that this meal contained much less phosphatides than that extd. with benzene, and as soon as the meal extd. with trichloroethylene was taken off the market, the sickness disappeared. An attempt was made to find out if other substances were extd. by the trichloroethylene that were not extd. by the benzene. Ground soy beans were first extd. with benzene, then with trichloroethylene and this last ext. was dissolved in benzene. The insol. residue was a brownish yellow wax-like substance, of a 42.9% ash content contg. much P_2O_5 , considerable Ca and very little Mg, while there was a residue insol. in strong acids giving a pronounced SiO_2 reaction.

J. C. JURRJEHS

Experiences in ensilage at the Royal Hungarian Agricultural Academy in Keszthely. LADISLAUS V. CSIKI. *Deut. Landwirt. Tierzucht.* 33, No. 7, 121-2(1929).—Time-temp. and fodder height(cm.)-time curves are given for the ensilage of green corn. The temp. was kept at 40-50°. Analysis of the silage after 5 1/2 months gave H_2O 83.16%, ash 1.35, crude protein 0.85, digestible protein 0.60, crude fat 0.46, crude fiber 6.28 and N-free ext. 7.90. Parallel analyses are given for an air-dried sample. B. C. B.

The composition and nutritive value of sugar-beet pulp. H. E. WOODMAN AND W. E. CALTON. School of Agr., Cambridge Univ. *J. Agr. Sci.* 18, 544-68(1928).—Crude fiber (20.3%) and N-free extractives (65.7%) constitute together more than 0.8 of the dry matter of sugar-beet pulp, the latter being deficient in respect to proteim ash and oil. The carbohydrate of sugar-beet pulp is mainly in the form of a pectose. The pulp is shown to be highly digestible in the ruminant organism. It compares very favorably with maize meal in respect to the digestibility of its N-free extractives and total org. matter, as well as in its content of digestible org. matter. The process of drying in the factory does not impair its digestibility. As affecting digestibility it is immaterial whether dried pulp is included in the rations of ruminants in the dry or soaked condition. It is advisable, however, with liberal allowances of the dried product, to soften well in water prior to feeding. The fibrous constituent of sugar-beet pulp is very little inferior to the N-free extractives in respect to digestibility, justifying the conclusion that it is present almost wholly in the form of simple cellulose. Almost 0.8 of the total dry matter of sugar-beet pulp is digested not by enzymic processes but by the agency of bacteria. The dried pulp is to be regarded as a carbohydrate concentrate, 1 lb. of which is equiv. to 0.8 lb. of maize or 0.9 lb. of barley in the productive part of the rations of ruminants. It is a cheap source of digestible carbohydrate.

P. R. DAWSON

Occurrence and distribution of I in fish and fish products (LUNDE) 11A. Dairy waste waters, their properties and their purification (PRITZKOW) 14. Garlic (KUROSAWA) 11D. The occurrence and characteristics of certain yeasts found in fermented honey (MARVIN) 11D. Filter for beverages (U. S. pat. 1,706,250) 1. Fermentation of sugars (Brit. pat. 295,648) 16. Alcohol recovery apparatus for baking ovens (Ger. pat. 471,086) 1. Laboratory mill suitable for comminuting feedstuffs (U. S. pat. 1,706,643) 1.

Treating grain with potassium carbonate. HENRY J. WHITE (to Bethlehem Milling Co.). U. S. 1,706,760, March 26. Grain such as wheat is heated to about 200° with K_2CO_3 and sugar (suitably in dil. soln.) in order to improve the properties of flour made from the wheat for bread making.

Baking bread. ROBERT L. CORBY (to the Fleischmann Company). U. S. 1,705,636, March 19. One side portion of the crust of a loaf of bread, during baking, is heated to a greater extent than the other side of the crust, so as to control and localize splitting of the crust during baking.

Milk. HENRICH BÖNING. Fr. 645,941, Dec. 20, 1927. Oil or fat hardened of H at 30-32° is added to milk which is afterward homogenized. The or fat may be injected into the milk under a pressure of 175 atm. in which case the homogenizing is not necessary.

Milk. HENRI CORBLIN. Fr. 646,190, May 5, 1927. Milk is preserved for transport by causing a rapid formation of a thin layer of frozen milk on the interior of the walls of the vessels. The vessels filled with milk, preferably at 0°, are plunged into a well-stirred freezing mixt. Cf. C. A. 22, 3795.

Butter. ALFRED GORRE. Fr. 646,115, Dec. 23, 1927. Cream, for the manuf. of butter, is sepd. after milking, and put in contact with a pure lactic ferment "Chevrotin"; it is then into a container with double walls sunk in the

ground to allow keeping of the cream in all seasons for 8 days and to facilitate the centralization in the creameries of good creams of a characteristic aroma.

Margarine and similar products. AKT.-GES. FÜR MEDIZINISCHE PRODUKTE CHEMISCHE FABRIK. Brit. 295,884. In the manuf. of margarine and similar edible fats, lecithin and cholesterol or phytosterol and fat mixts. are obtained by alc. extn. from animal or vegetable oils or fats and these mixts. are added to the basic fat mass. Products from egg-yolk oil or soy-bean oil may be added to margarine.

Preserving egg material. A. H. PENFOLD. Brit. 296,012, May 23, 1927. Egg yolks or mixed yolks and whites are preserved by adding dextrose (suitably 10–20%) and storing at a temp. below freezing point (suitably about -25°).

Casein. CARL ALBRECHT BAECHLER. Swiss 127,781, June 29, 1927. Casein is obtained by adding a casein-pptg. medium to milk and stirring strongly. The product is mixed with dry casein until a homogeneous moist whole is formed. This is then dried.

Filter for coffee infusions or other beverages, etc. C. G. BROOKS. Brit. 295,812, July 18, 1927.

Freeing coffee berries from pulp and washing them before drying. F. KRUPP GRUSONWERK A.-G. Brit. 295,515, Aug. 31, 1927. An app. is described; and the mixt. of pulp and mucilage produced may be used to form combustible briquets.

Shaft drier for sliced fruits and vegetables. HANS TZITSCHKE. Ger. 471,452, Aug. 4, 1927.

Pectin. PECTINERIE DU KERVOR. Fr. 645,993, Dec. 21, 1927. Apples or apple waste is given a preliminary treatment with water contg. an inorg. acid to ext. sugar, salts and substances other than pectin, which is then extd. in the usual manner.

Activated product from yeast. I. S. MACLEAN. Brit. 295,757, May 23, 1927. Yeast is incubated in a soln. contg. phosphates and carbohydrates and the sterols or sterols and fats so obtained are subjected to activating radiation. The product may be added to margarine.

Yeast compositions. BAYLIS M. DAWSON (to The Fleischmann Co.). U. S. 1,706,564, March 26. A substantially dry compn. comprising yeast particles and assocd. solids (and which may also comprise malt-ext. solids) may be prepd. by a method of spray desiccation under properly regulated conditions, which are described. U. S. 1,706,565 relates to substantially dry compns. comprising yeast particles encapsulated by the solids of a fruit juice such as orange juice and which may also contain milk solids. U. S. 1,706,566 relates to a compn. in substantially dry form comprising particles of yeast encapsulated in and assocd. with malt-ext. solids and fruit-juice solids.

Drying hay, straw, beets, etc., by coiled heating pipes within a stack of the material. C. LYON. Brit. 295,482, July 4, 1927. Mech. details are specified of an app. in the heating coils of which water heated to above 100° is preferably used as the heating medium.

Drying hay, straw, beets, or other materials. C. LYON. Brit. 295,801, July 4, 1927. The material is arranged in a stack with internal heating coils through which water under pressure and heated to above 100° may be forced while air is forced through the stack. Devices may be provided to check the heating or circulation of the water if the air current is stopped.

The right of protest in granting patents. GUSTAV SCHUCHARDT. *Chem.-Ztg.* 53,

61-2(1929); cf. *C. A.* 22, 3714.—Objections to current practice in German patent procedure are voiced. In many cases such protests are lodged only to embarrass the applicant, for the sake of competition, to delay proceedings or to give the objector access to information belonging properly to the applicant.

The demand for chemical engineers. W. BADGER. *Univ. of Mich. Ind. Eng. Chem., News Ed.* 7, No. 6, 3(1929). E. J. C.

The role of surface energy in chemical engineering. W. E. GIBBS. *Chemistry & Industry* 48, 127-37(1929).—G. gives a good discussion of the application of surface energy phenomena to chem. engineering. Surface energy is explained and its application is shown to adsorption, scale prevention, emulsification, emulsification and demulsification, flotation, lubrication and contact catalysis. M. C. ROGERS

Squandering fuel in commercial plants employing heat. W. GRAULICH. *Chem.-Ztg.* 53, 49-50(1929).—In a series of illustrations based upon actual practice the costs incident to so-called "trifling faults" in plants management and up-keep are shown. Included are leaky packing of joints, cutting out a feed-water heater, omitting feed-water purification, cleaning boilers, not saving condensate for boiler use, poor insulation, not preheating feed water, omitting superheating and condensation. Rigid accounting methods covering fuel and power costs and efforts to improve plant practice are bound to pay for themselves. W. C. EBAUGH

New coating for pressure stills. J. C. MORRELL, W. F. FARAGHER AND V. MEHLER. *Oil & Gas J.* 27, No. 29, 55, 150(1928).—A non-corrosive, adhesive, protective coating for still lining comprises furnace cement 60 lbs., white silica foundry sand 30 lbs., water glass (40-43° B ϵ), technical 1 gal.; asbestos, short fiber 1 1/4 lbs. and water 200-1000 cc. per 100-lb. batch. The coating is applied to the sand-blasted surface in layers preferably 1/16 to 3/16 in. thick and covered with a brushing soln. consisting of a mixt. of 5 lbs. furnace cement (50-50 Adamant-Sansé mixt.) and 1 gal. water glass (40-43° B ϵ) and about 3 pints water. The lining is cured by heating at a regulated rate to about 900° F. M. B. HART

Progress report of pipe line and production of the A. P. I. general committee on corrosion for 1928. E. P. BLV. *Am. Petroleum Inst., Bull.* 10, No. 2, 76-8(1929).—In a review of 120 questionnaires returned from 24 business units several valuable requirements have been suggested, such as applying the main coat or the prime coat at the mill, routing pipe lines around the corrosive area, giving more concd. thought to tankage corrosion, durable screens, casing and tubing. As a result of these activities a definite program has been laid out for future work involving (a) development of other codes of good practice for all materials showing merit as pipe line coverings, (b) making more extensive field investigations on present coatings to serve as a basis of future selections, (c) studying the economic aspects of pipe-line corrosion problems and (d) conducting cooperative field exptl. work with the Bureau of Standards, pipe-line companies, and coating manufacturers. J. L. E

The use and behavior of protective coatings on underground pipes. GORDON N. SCOTT. • *Oil & Gas J.* 27, No. 29, 127-8, 195(1928); *Am. Petroleum Inst. Bull.* 10, No. 2, 78-93(1929).—S discusses a few of the important aspects of care in the application of protective coatings, the types of failure which have been found to occur in service, and the manner in which false conclusions may be drawn from tests on specimens buried in selected soils. One of the objections to mill-coated pipe is the ease of rupture of the coating by rough handling before use. Continuity of the coating is essential so as to prevent localized corrosion; hence patch work, unless done very carefully, should be avoided. Since oil-soaked earth will readily dissolve the coating, it is necessary that all collars be properly caulked to prevent leaks. Air entrapped in the coating will cause rupture of the fabric. The added life that may be realized from the application of a particular coating is a function of the conditions of service to which the coating will be subjected. Generally, the destruction of a protective coating in service may be either chem. or phys. or a combination. A soil which expands or contracts with a change of moisture content and which has the ability to adhere to the coating causes considerable damage to certain classes of protective coatings; this may be called the "soil stress effect." Chem. changes may involve oxidation, loss of volatile constituents, and soly. of bitumens in oil. Phys. changes may be due to loss of bond between asphalt and metal, softening and flowing of the coating, distortion of the coating by movement of the earth caused by uneven trench bottoms and settling of the back-fill earth. Temp. changes cause considerable distortion, cracking, and checking of coatings. Lab. tests show that soils which give surface or subsurface checking may be expected to have a distorting effect upon coatings. Such soils are usually highly col-

loldal. No direct relation between soils which are corrosive to bare pipe and which are highly destructive to coatings was noted.

"Schades plastic protective binding" as a protection against corrosion for pipes. J. L. E. ERNST VOGELSLANG. *Chem. Fabrik* 1929, 77-8.—A recently introduced tape or binding material for protecting piping and cables against corrosion is said to yield good results. The fabric is coated with a wax-like substance consisting of paraffin hydrocarbons, and the tape is applied only "on the job" and not in the factory. W. C. E.

Are present cylinder test regulations practicable? GLEN D. BAGLEY. *Chem. Markets* 24, 169-75(1929).—Interstate Commerce Commission tests for gas cylinders demand that every cylinder must withstand a test pressure equal to $1\frac{2}{3}$ times the charging pressure at 70° F., with a permanent expansion not greater than 10% of the total and without any previous pressure greater than $\frac{1}{3}$ that of the test pressure having been applied. And one cylinder out of each 200 must stand a crushing test to 6 times the wall thickness without cracking, and also tensile test specimens from this cylinder or another must show an elongation of not less than 10% on an 8" specimen, with an elastic limit of not more than 70% of the ultimate. To obtain such information without harming the cylinders, tests were made and results plotted showing the relation between the expansion of a cylinder and the pressure applied up to a distance beyond the elastic limit. Curves were derived that showed the possibility of judging the fitness of a cylinder without destroying its usefulness. The only factor of serious consequence in the life of an initially satisfactory cylinder is internal corrosion. The extent to which it has occurred can be detd. by noting the elastic expansion of the cylinder, and measurements of this must be made every 5 yrs. to comply with ICC regulations anyway. Moreover tapping a cylinder with a light hammer will indicate by the sound whether serious corrosion has taken place. Thus simple non-destructive tests are available which make it possible to det. wall thickness and condition of the steel on every new cylinder; and the 5 yr. and hammer tests give information as to condition of the walls. W. C. EBAUGH

Crushing and grinding. II. The relation of measured surface of crushed quartz to sieve sizes. JOHN GROSS AND S. R. ZIMMERLEY. *Am. Inst. Min. Met. Eng., Tech. Publ.* No. 126, 8 pp.(1928).—Surface measurements were made by the soln. rate method developed by the authors (*C. A.* 22, 1072). Owing to fractures, the surfaces of which are measured in part, the ratio of measured to theoretical surface is much larger for coarse than for fine particles. The ratio varies from 2 for the 0.1 mm. size to 3.5 for the 0.7 mm. size. Ottawa sand, which is free from fractures, showed a const. ratio of about 1.3. The av. size of the particles in the material finer than 200-mesh is usually much less than 37 microns. III. Relation of work input to surface produced in crushing quartz. *Ibid Publ.* No. 127, 10 pp.—A crushing device was developed in which a heavy ball was allowed to drop upon a plunger in a steel mortar containing the quartz sample. The work not used in crushing was measured by the deformation of 3 Al wires placed radially under the mortar. The exptl. results showed that the new surface produced was directly proportional to the work input. The major portion of the work expended, even in comparatively coarse crushing, is consumed in making material smaller than 200-mesh. HANS C. DUUS

Industrial carbon monoxide poisoning. MAX GRÜNEWALD. *Brennstoff u. Wärme-wirtschaft* 11, 51-3(1929).—A review mainly of the physiological effects of CO. F. S. GRANGER

Loss calculations in dissolving, leaching and extraction. C. V. IREDELL. *West-inghouse Lamp Co., Bloomfield, N. J. Chem. Met. Eng.* 35, 685-6(1928); *Eng. Mining J.* 127, 201-2(1929).—The following equations show a method of computing losses without weighing the residue: (1) when the desired constituent remains in the residue in the same form in which it existed in the starting material
$$L = 100 B \frac{(1-A)}{A(1-B)}$$
 (2) when the desired constituent remains with the residue as an entirely different compd. than that in which it existed in the starting material
$$L_1 = \frac{100 B_1 (1-A)}{A(1-B_1 f)}$$
 (3) when the desired constituent remaining in the residue is partly as the unchanged original form and partly as the converted compd.:
$$L_1 = 100 (B + B_1) \frac{(1-A)}{A(1-B-B_1 f)}$$
 A = the wt. of the desired constituent in the starting material per unit wt. of starting material; B = the wt. of the unchanged desired constituent in the residue per unit wt. of residue; B_1 = the wt. of the desired constituent in the residue which has been converted to a different compd., per unit wt. of residue; A , B and B_1 are provided by chem. analysis; f = the

conversion factor of the desired constituent from its original form in the starting material to the sol. compd. existing in the residue; X = the wt. of total residue per unit weight of starting material; L = the loss in percent of the total desired constituent.

L. A. PRIDGON

Manufacture of magnesia insulating materials. FRIEDRICH E. M. BUSCHMANN. *Chem.-Ztg.* 53, 31-2(1929).—Basic Mg carbonate and asbestos wool serve as raw materials for making molded forms of insulators, the Mg compd. being made from burned magnesite, H_2O and CO_2 under definite conditions of temps. and pressure so as to get the desired phys. properties, i. e., low cond. and light weight per unit vol. The mech. operations involved are described briefly.

REEDY, JOHN H.: *Industrial General Chemistry.* Urbana, Ill. 384 pp.

ROTH, WALTHER A.: *Grundzüge der Chemie für Ingenieure.* 2nd ed. Braunschweig F. Vieweg & Sohn. Akt.-Ges. 265 pp.

Purification of gases. SOC. ANON. POUR L'EXPLOITATION DES PROCÉDÉS ÉDOUARD URBAIN. Fr. 646,462, May 18, 1927. Last traces of impurities are removed from gases, by liquefying the gas and treating with absorptive C.

Purifying gas admitted to transformers. A. G. ELLIS and METROPOLITAN-VICKERS ELECTRICAL CO., LTD. Brit. 296,160, June 30, 1927. Air or other gas is dried or deoxidized by passing over the surface of desiccants such as $CaCl_2$ or deoxidizing agents such as ground Cu and NH_4Cl or P arranged in layers. An app. is described.

Gas-purification plant. P. SCHLÄPPER. Swiss 128,189, Sept. 10, 1927. Impurities are removed from gases by washing and treating with a soln. which is insol. in the washing liquid and which forms easily removable double compds with the impurities.

Gas adsorption. S. PILAT. Brit. 295,874, Nov. 22, 1927. In passing a gas through adsorbent material, first in one direction and then in the opposite direction, it is passed in one direction through the whole height of the adsorbent material and in the opposite direction through only a part of it. By using several adsorption chambers in rotation the process may be made continuous.

Preventing gas absorption by liquids. FIRM OF P. LECHLER. Brit. 295,319, Aug. 9, 1927. In preventing corrosion of iron submerged in water, or for like purposes, the body of liquid is covered with another lighter liquid layer such as mineral oil which may contain dissolved bitumen to increase its viscosity.

Absorption of carbon dioxide from gases. GES. FÜR LINDER'S RISMACHINEN A.-G. Ger. 480,840, Aug. 11, 1926. Aq. NH_3 salt soln. with less than 5% free NH_4OH and more than 5% free $(NH_4)_2CO_3$ is employed as the absorbent.

Use of oil to facilitate separation of dust from air or other gases. O. SÖDERLUND, T. GRAM AND TECHNO-CHEMICAL LABORATORIES, LTD. Brit. 295,233, May 4, 1927. An app. is described.

Separating particles suspended in a liquid. KARL T. R. LUNDGREN. Fr. 646,027, Dec. 21, 1927. Tubes contg. the liquid are fixed in an inclined position on a frame on a rotating vertical axis, so that a centrifugal action is obtained. The app. may be used for blood analysis.

Separating liquids. CHARLES E. DERACKER. Fr. 646,421, Dec. 28, 1927. Liquids of different densities are sepd. by dipping into the liquids a container having a vertical tube opening below the edges of the container and terminating below the container in a funnel open at the base. The mouth of the funnel is placed below the surface of the heavier liquid which flows upward into the container.

Clarification of emulsions. G. STADNIEV, ROBERT KLASSON and VICTOR KIRICHENKOV. Ger. 468,185, Oct. 23, 1924. The sedimentation velocity of turbid liquids, the like is accelerated by stirring in coagulated colloids such as peat.

Thus, coagulated peat accelerated the sedimentation of pptd. CdS and Fe_2S_3 hydrosol. Cf. C. A. 23, 655.

Solvents and dispersing agents. I. G. FARBENIND. A.-G. Fr. 646,816, Jan. 7, 1928. Aliphatic or mixed aliphatic-hydroaromatic derivs. of NH_3 contg. one or more alkylhydroxylic or cycloalkylhydroxylic groups are used as solvents and dispersing agents for industrial substances of animal, vegetable or other origin. Examples are given of the use of cyclohexyldiethanolamine, cyclohexylmonoethanolamine and triethanolamine as *dispersing agents for dyes and solvents of oils, etc.* The butylethanolamines are also mentioned.

Effecting chemical reactions. VEREIN FÜR CHEM. IND. A.-G. (Hans Walter, inventor). Ger. 471,267, May 23, 1924. See Swiss 127,243 (C. A. 23, 1188).

• **Cooling steam.** SIEMENS-SCHUCKERTWERKE A. G. (Hans Gleichmann and Walde-mar Stender, inventors). Ger. 471,225, Aug. 17, 1924. App. is described for use in processes, e. g., *sugar manuf.*, in which it is desirable to use steam at a temp. not exceeding a given max. The steam is cooled by water in a surface heat exchanger, the amt. of steam being controlled in accordance with the pressure of the cooled steam, and the amt. of water in accordance with the temp. of the water.

Oil extracting. I. G. FARBENIND. A. G. Fr. 646,703, Jan. 4, 1928. Oil is extd. from solid substances contg. it, such as hydrogenated coal, by means of liquid SO_2 which may be mixed with C_6H_6 or other solvents.

Centrifugal lining of pipes and tubes with bituminous material. BRITISH MANNES-MANN TUBE CO., LTD., and R. F. WEISER. Brit. 295,267, April 5, 1927. A hot compn. is used comprising natural asphalt or bitumen including its normal mineral content, and a fluxing oil, e. g., Trinidad native bitumen having a siliceous content of 40% mixed with 20% of asphaltic oil.

Coating pipes with asphaltic or cementitious materials, etc. BRITISH MANNES-MANN TUBE CO., LTD., and R. F. WEISER. Brit. 295,340, April 5, 1927. The coating material is projected from a nozzle in the form of a flat strip the impact of which serves to rotate the body being coated, and the coating is smoothed by pressing during the rotation. An app. is described.

Gas masks. LES FILS AÎNÉS DE A. BAUDOU. Fl. 646,226, May 10, 1927. Rubber foil which is not attacked by yperite and may be used in masks is made by covering the foil with linseed oil and vulcanizing.

Refrigerator. GEORG THOMAS and PETER SCHLUMBOHN. Fr. 646,801, Jan. 6, 1928.

Refrigerating machine. PLATEN-MUNTERS REFRIGERATING SYSTEM AKTIEBOLAG. Ger. 471,475, Aug. 1, 1926. In a continuously operating absorption refrigerating machine of the kind contg. an inert gas for equalizing the pressure, the pipes conveying the cooling water are of Cu and are arranged in metallic contact with the Fe condenser coil and the Fe wall of the absorber. Cf. C. A. 23, 1971.

Refrigerating system of the absorption type. G. MAURI and R. F. BOSSINI. Brit. 296,109, Feb. 25, 1927. Various details are described of a system in which a pressure equalizing inert gas such as He, H, N or A may be used. Brit. 296,140 also describes a refrigerating system of the same general type.

Refrigerating system of the reversing absorption type. J. O. BOVING. Brit. 295,836, Aug. 31, 1927.

Refrigerating system of the reversing absorption type. SULZER FRERES SOC. ANON. Brit. 295,371, Aug. 11, 1927. An app. is described.

Compression refrigerating machine. ANDREW A. KUCHER. Ger. 471,456, Mar. 8, 1924. Corresponds to Brit. 217,178.

Refrigerating apparatus of the compression type. F. R. WEST (to Rice Products, Inc.). Brit. 295,583, Aug. 13, 1927. Structural features.

Pressure regulator for refrigerators. SOC. NOUVELLE DU FROID INDUSTRIEL. Fr. 646,354, May 12, 1927.

Thermostatic device for refrigerating apparatus. IRVIN G. THOMAS (to Westinghouse Elec. & Mfg. Co.). U. S. 1,705,690, March 19.

Heat insulating material from peat. GEORG KELLER. Ger. 467,223, May 7, 1924. Heat insulating material is made from peat by mixing it in a finely divided state with cork and grit or sand and pressing the mass in molds at 150° .

Porous silica suitable for use as a heat insulation material. H. L. WATSON (to British Thomson-Houston Co., Ltd.). Brit. 295,628, Aug. 15, 1927. Silica is rendered porous by heating and cooling, impregnated with an org. material, and then heated rapidly until plastic so that the org. material is volatilized and forms minute bubbles in the silica, e. g., quartz sand may be heated to about 1700° for a half hr., cooled, mixed

with shellac soln., molded, slowly heated to about 400° and then heated rapidly to about 1750°.

Electric cables. FELTEN & GUILLEAUME CARLSWERK A.-G. Brit. 295,932, Aug. 20, 1927. Paper tape insulation on high-tension cables is wound in an overlapping manner in the innermost layers and in an abutting manner in the middle and outer most layers.

Deep-sea electric cables. FELTEN & GUILLEAUME CARLSWERK A.-G. Brit. 295,923, Sept. 16, 1927. Cables such as those with paper or air insulation are armored with wires or flat strips of light metal such as Al alloy, assocd. with steel wires. The armoring is covered with gutta-percha or rubber and a lead sheathing is placed over this.

The medicinal springs of South Africa. Supplement II. M. M. RINDL. Gray Univ. Coll., Bloemfontein. *S. African J. Sci.* **25**, 116-26(1929). Analyses are given of the waters of numerous medicinal springs of South Africa. A. I. H.

The hydrogen-ion concentration of surface waters around the Cape Peninsula. LANCELOT HUGHES AND ALEXANDER ZOOUD. Univ. of Cape Town. *S. African J. Sci.* **25**, 325-8(1929).—The pH of 34 samples of water taken at different places and times around the Cape of Good Hope peninsula have been determined. The mean av. results were 8.16 ± 0.028 in one series and 8.18 ± 0.024 in the other case. These results reinforce the view that sea water in different parts of the world varies very little in H-ion concn. ALBERT L. HENSEL.

Comparative study of sea-water densities determined by various methods. ENMA BARDAN MATEU. *Inst. Españ. Oceanografía Notas y Resúmenes* II, No. **14**, 1929, 12 pp.—Allémantet has obtained a max. difference of only 5 units in the 5th decimal place between Cl and the pycnometer method. But on comparing the data the errors are much greater than this, up to 2 in the 4th place. Densities from refractive indices have a max. difference of 3 or 4 units in the 4th place. Most upper values have been obtained by refractive-index methods. A plot is given of values obtained (a) by pycnometer method, (b) by refractometer, (c) from Cl detns. Errors to which the refractive index and Cl methods are liable do not obey any const. law. Alteration of density on keeping has been indicated by Makaroff, with very phosphor. salt water; he intimates that the organisms present may affect the density. Finally there may be biol., phys. and chem. reasons for the density variations. S. L. B. ELLIOTT.

Determinations of organic matter in sea waters. JOSE GIRAL PEREIRA. *Inst. Españ. Oceanografía Notas y Resúmenes* II, No. **4**, 25 pp.—The org. matter may include living cells of the microplankton and bacteria, spores, dead matter, hydrocol. cells and chemically dissolved matter. Hence albumins, fats, carbohydrates, carotinoids and anthocyanins may be present. From the dead detritus one may expect cotones, prosthetic groups, polypeptides, amino acids, amines, etc., and putrefactive products, zymases and diastases, mercaptans, and the like, cystine and the like. H₂SO₄ and H₂SO₃, glucosides, fats, lipoids and glycerides may be present. A sept. according to chem. orders of the org. matter is not possible, and analytical methods for these orders are very imperfect. The relation with O₂, CO₂ and oxidants has been studied particularly the action with permanganate. The Schulze-Trommsdorff (alk. KMnO₄ acidulation, addn. of oxalic and back titration) was used although recognized as tentative. The Algeiras Bay has a factory discharging org. matter into the water. The results for June-July 1922 are given in a table. S. L. B. ELLIOTT.

Variations in salinity and oxygen dissolved in sea water in Algeiras Bay during the voyage of the "Averroes." A. GILA Y ESTABAN. *Inst. Españ. Oceanografía Notas y Resúmenes* II, No. **7**, 1924.—Depth, temp., time, Cl‰, salinity ‰, etc., are given for some 192 samples, some of the data being set out graphically. Data collected by the "Thor" in 1910 in the Mediterranean are also given. The Mohr-Winkler method was used for Cl and Winkler methods for O₂. In Algeiras Bay there is a surface layer of min. salinity. Two classes of water exist analogous to waters in the Mediterranean.

One, less saline, floats, and produces a current parallel to the coast; the second, more saline, below, periodically receives injections of water from the Mediterranean. Variations in dissolved O_2 are insignificant at the surface but greatest at 30 m. below the surface. The relations calcd. by G. are not const. A bibliography of 58 references is given.

Reaeration of water by algae. EDWARD C. CROMWELL. *Public Works* 59, 346-7 (1928).—The effluent of the Baltimore sewage plant empties into the Back River. The dissolved-O content of the river was 80-180% satn. The supersatn. is due to the prolific growth in the water of algae, which is caused by the stimulating effect of the dissolved org. matter. Algae are very important factors in the reaeration of water and in the oxidation process.

The action of active chlorine on aquatic plants. K. GEMEINHARDT. *Kl. Mitt. Ver. Wasserversorg. Abwasserbesetig.* 2, 124-30; *Chem. Zentr.* 1927, II, 1743.—The introduction of strongly chlorinated waste water into streams causes damage to the vegetation and microorganisms, if the water contains more than 15 mg. Cl per l. For removing undesirable vegetation in water reservoirs of technical water, cooling towers, etc., about 100 mg. Cl per l. may be added to the water during a working pause and allowed to act as long as possible. Mechanical removal of the dead vegetable matter should bring relief from the nuisance for some time.

The water of several Hungarian city aqueducts, wells and bathing places near Lake Balaton and that of several railroad stations. I. SZANYI. *Kiserl. Kozl.* 31, 1-20 (1928).—891 samples of drinking water were analyzed. Water of city aqueducts was proved to be good; 52.8% of the examd. railroad-station wells and 37.5% of bathing place wells was found drinkable. The amount of water produced in cities with aqueducts varies from 29.7 to 182.5 l. to the person daily. Aqueducts should be established, if possible, since ordinary wells yield good drinking water only in case of frequent cleanings.

The chemical control of boiler plant. C. N. RIDLEY. *Ind. Management* 15, 360-1 (1928).—A discussion of boiler feed water treatment and of problems relating to combustion.

Embrittlement prevention in steam boilers. FREDERICK G. STRAUB. *Power Plant Eng.* 33, 173-4 (1929).—Boilers operated for 13 years at a pressure of 160 lbs., in which a ratio of Na sulfate to total alk., expressed as Na_2CO_3 , equal to 2 was maintained, show no embrittlement. Two plants in the Champaign Urbana district operated at 160 lbs. pressure on untreated water have encountered embrittlement. In another community a well water free from Na_2CO_3 received water treatment introducing a high Na_2CO_3 alk. and a low SO_4 content: a plant using this treated water encountered embrittlement while another using the raw water was free from trouble. Adoption of recommendations of the Am. Soc. of Mech. Eng. Boiler Code Comm. in 1926 advising ratios of alk. to Na_2SO_4 at various steam pressures has done much toward helping plants eliminate trouble. The proper ratio should be maintained at all times, as embrittlement may act quickly. Half the proper ratio is no better than none. Phosphate treatment, which maintains the proper ratio between alk. and sol. phosphate content (not total phosphate), seems to be more desirable as a lower ratio may be effective. Tannate and acetate are helpful in inhibiting embrittlement.

Absorption of oxygen by alkaline tannates. E. P. FAGER AND A. H. REYNOLDS. *Ind. Eng. Chem.* 21, 357-9 (1929).—A study at room temp. of the absorptive properties of various com. alk. tannates as regards their relative efficiencies in boiler-feed waters for the prevention of corrosion. Com. tannins in alk. soln. absorb large amts. of O_2 —in some cases almost as much as pyrogallol.

Definitions of terms used in sewerage and sewage-disposal practice. Am. Soc. Civil Eng. and A. P. H. A., *Joint Committee Rept.* 19 pp. 1928.

Sewage from dye works, its effect on streams, and the possibility of purifying it. A. PRITZKOW. *Kl. Mitt. Ver. Wasserversorg. Abwasserbesetig.* 1, 149-54 (1925); *Chem. Zentr.* 1927, II, 1745.—Dye waste waters may be discolored by bleaching, chem. clarifying, or filtering over brown-coal cinders.

Physical and chemical considerations of streams into which sewage is discharged. A. SCHULZE-FORSTER. *Kl. Mitt. Ver. Wasserversorg. Abwasserbesetig.* 3, 249-63; *Chem. Zentr.* 1927, II, 1745.—Water courses that receive sewage must be examd. as to what extent their properties are altered by such an influx. Numerous methods are discussed of taking samples and of carrying out the phys. examn. with regard to transparency, color, odor, reaction and cond. The use of the interferometer for detecting the origin of the pollution is discussed. Of the chem. methods of examn., particular stress is put on the significance of the acid-combining power of the stream, which is of importance

when acid waste waters are introduced into the stream. Acid-combining power is defined as the amt. of SO_2 in mg., with which 1 l. of the water can combine. G. S.

Dairy waste waters, their properties, and their purification. A. PRITZKOW. *Kf. Mitt. Ver. Wasserversorg. Abwässerbeseitig.* 1, 27-31(1925); *Chem. Zentr.* 1927, II, 1745. The purification of dairy waste waters may be limited to the retention of fatty constituents and of the coarse particles, if the conditions are favorable in the stream into which the waste is discharged. If they are unfavorable, as will be the case in most of the dairies, the waste water should be used on sewage irrigation fields or treated on trickling filters or by biol. methods. G. SCHWOCH

Chemical aspects of stream pollution by phenols. EMERY J. THERIAULT. *Ind. Eng. Chem.* 21, 343-6(1929).—A study of the purely chem. aspects of stream pollution by phenols as distinguished from problems of inspection, regulation, or sanitary control. Exptl. results indicate that under certain restrictive conditions, the Gibbs method is capable of giving reliable information. This procedure applied to domestic sewage indicates the presence of 100-500 parts per billion of phenol while with polluted waters values ranging from 1 to 2 parts per billion have been obtained. In the case of coagulated and filtered waters derived from polluted sources sep. evaluation of various modifying factors will be necessary before definite conclusions can be drawn concerning the occurrence of tastes following chlorination, which can be referred to substances of sewage origin. W. H. ROYCE

Biochemical oxidation of phenolic wastes. F. W. MOILMAN. Sanitary Dist. of Chicago. *Am. J. Pub. Health* 19, 145-56(1929).—A modification of the Gibbs colorimetric method for the detection of phenol in amts. less than 2500 p. p. b. was used. The reagent, 2, 6-dibromoquinone chloranide, was found to be sp. for phenols. Three large coke or steel factories add large quantities of phenolic wastes to the sewage. Lab. expts. show that the addn. of less than 2% of NH_3 -still wastes to sewage greatly increases the 5-day biochem.-O demand. Org. N and total bacteria also increase perceptibly. On a slow sand filter 1% (25-35 p. p. m.) or less of phenolic wastes could be handled satisfactorily. The activated-sludge process can handle 30-40 p. p. m. of phenol from NH_3 -still wastes without serious impairment of the quality of the effluent. Anaerobic bacteria are found to be more resistant to phenolic wastes than aerobes. Reinoculation, using 10% inoculum of a previously used aerated sludge, accelerates oxidation and reduces the time from 15 to 9 hrs. Phenolic wastes oxidize much more rapidly at higher temps. (130°). At 20° the phenol content is decreased to 100 p. p. b. in 3.4 days while at 10° it requires 7.4 days for a similar decrease. C. R. L.

Colorimetric determination of nitrates in waters (UMBERTO DE NARDO) 7. **Chemical composition of Woods Hole sea water** (PAGE) 11A. **Elimination of mosquito oöfers** broad market for special oils (GINSBURG) 22. **Differentiation of the coli and aerobes groups of bacteria** (SALLE) 11C.

Softening water. STANLEY A. SANFORD. U. S. 1,705,589, March 19. BaF_2 is used to ppt. the bases which cause temporary and permanent hardness, without addn. of any other coagulating substance.

Apparatus for softening water by chemical treatment. CHARLES P. EINHAEGER (to The Duro Co.). U. S. 1,706,777, March 26.

Filter for water, etc. J. MUCHKA. Brit. 295,520, Sept. 28, 1927. The filtering material, such as sand, gravel, quartz, or carbon, of a filter for water is sterilized by steam generated in the lower part of the filter or in an adjacent connected container. Various structural details are described.

Apparatus for aerating sewage. P. I. DONROKHOTOV. Russ. 5445, May 31, 1928.

Treating- and settling-chamber construction for bacterial purification of sewage. H. E. ELROD. Brit. 295,863, Oct. 24, 1927.

Sterilizing air. JOSEPH F. SCHILLER and WALTER U. WESCOTT. U. S. 1,706,594, March 26. Air is compressed to about 3 atm. and then expanded by successive steps in small streams to a pressure of about 2.5 atm. An app. is described.

15—SOILS, FERTILIZERS AND AGRICULTURAL POISONS

J. J. SKINNER

Soil investigations and subsoil treatments. FRANK H. ENO. Ohio State Univ. *Roads and Streets* 49, 39-44(1929).—E. describes soil properties and lab. methods of detg. the value of the properties in connection with the effect of the soils upon pavements laid upon them. Drainage and methods of changing the qualities of a soil are discussed. L. B. MILLER

Soil profile in the Eastern Gezira. H. GREENE. Wellcome Tropical Research Labs., Wad Medani, Sudan. *J. Agr. Sci.* 18, 518-30(1928).—Data are presented on the vertical distribution of salts in the soil, as estd. by the cond. method. Field observations on the soil profile are included. The distribution of salts is generally related to compactness of the soil profile as judged by the distribution of gypsum, CaCO_3 , aggregates and soil color. The relation already established between salt content and fertility is now expressed as a relation between compactness of profile and fertility. The data agree well with geological views as to the origin of the soil. Influences of which the soil profile is a product are also discussed. P. R. DAWSON

Soil permeability in the Eastern Gezira. H. GREENE. Wellcome Tropical Research Labs., Wad Medani, Sudan. *J. Agr. Sci.* 18, 531-43(1928).—An account is given of studies of moisture content in the field. The results agree with Joseph's (C. A. 20, 468) view that the relation between salt content and fertility is chiefly due to the effect of Na salts on soil texture. The effect of 14 days flooding is taken as a measure of permeability in the field and confirmatory results of this test were obtained when applied to 2 areas whose agricultural value had previously been measured by lab. studies and field observation of the soil profile. The genesis of the Gezira soil is discussed with regard to the relation between salt content and fertility and with regard to the use of gypsum as a corrective. Marked improvements in permeability have been brought about by application of this substance. P. R. DAWSON

The nitrogen content of Red River Valley soils. J. M. ELLIS AND WM. SHAPER. Manitoba Agr. Coll. Winnipeg. *Sci. Agr.* 9, 231-48(1928).—Numerous analyses showed a N content of 0.3-0.6% with an av. of approx. 0.42 in the surface 7 in. of soil. Many tongued intrusions occur in these soils. The N content of the intrusions was considerably higher than in the normal profiles. The cause of tongued intrusions is believed to be the cracking and opening up of the highly colloidal clay soils through shrinkage during drought. These fissures then become filled with surface soil and org. matter through the action of wind and rains. The dark tongued intrusions are shown to be of different forms, depending upon the phys. properties of the soil material. A peculiar broad and relatively shallow type, coexistent with a highly developed hummock condition of the surface, is caused by differential shrinkage and expansion where the profile was composed of clay underlaid by bedded very fine sandy clay. C. R. F.

Present knowledge concerning soil acidity. H. M. NAGANT. La Trappe, Can. *Sci. Agr.* 9, 186-91(1928).—A review. C. R. F.

Iodine in soils and plants. R. KÖHLER. Prussian Geological Inst., Berlin. *Z. angew. Chem.* 42, 192-7(1929).—Sixty-one soil samples were analyzed for I, humus and . . . The results varied with the kind of soil, previous treatment and location in the profile. Three of the soils were next used as germination beds for rye. After 18 days the plants were removed and the soils again analyzed for I. The content was distinctly lower. M. H. SOULE

Nitrogen fixation by soil microorganisms. P. G. KRISHNA. Cornell Univ. *J. Agr. Sci.* 18, 432-8(1928); cf. C. A. 22, 2428; 23, 1153. Fungi are responsible for the fixation of very small quantities of N, while the *Azotobacter* and *B. amylobacter* groups are the important N fixers in the soil. *B. amylobacter* is able to fix 4-5 mg. of N per g. of glucose consumed. It has an optimum range of pH between 6.0 and 7.0, while the optimum for *Azotobacter* lies between 7.0 and 8.4. *Azotobacter* utilizes the org. acids produced during the fermentation of glucose as sources of energy for N fixation in the absence of glucose; *B. amylobacter* does not, or only to a limited extent. Large

quantities of glucose do not favor an efficient N fixation, as large quantities of the org. acids produced affect the reaction of the media, rendering the organisms inactive. The N-fixing organisms appear to be equally well represented in the heavy and light soils.

P. R. DAWSON

The use of alcoholic salt solutions for the determination of replaceable bases in calcareous soils. O. C. MAGISTAD AND P. S. BURGESS. *Ariz. Agr. Expt. Sta., Tech. Bull.* 20, 481-97(1928).—The NH_4Cl method for the detn. of positive ions in base-exchange reactions is inaccurate in calcareous soils. The reasons are: (1) org. matter is dissolved from the soil by the NH_4Cl ; (2) a portion of the Ca appearing in the filtrate is dissolved Ca, mainly from CaCO_3 and is not exchangeable Ca; (3) the const. presence of dissolved Ca prevents the replacing action from going to completion and (4) an error may arise from the mech. loss of the dispersed base-exchange complex, whenever exchangeable bases are detd. by filtration or *percolation methods*. Two methods were studied experimentally, a percolation method especially adapted to routine analyses where large nos. of detns. are required and a *filtration method* adapted especially for small nos. of detns. The method here proposed for making detns. of replaceable bases in calcareous soils employs alc. (Et or Me) salt solns. as the displacing agents. The authors prefer 0.1 N BaCl_2 in 68% EtOH. It is found that the activity of such a soln. approaches that of an aq. soln. and that the soly. of CaCO_3 in the alc. soln. is extremely low (between 10 and 15 p. p. m.). By percolation methods, a large no. of detns. can be made at once with a min. of time and effort on the part of the analyst. The EtOH is evapd., the Ba pptd. as the chromate and the Ca, Mg, and other bases are detd. in the supernatant liquid by the soap-titration and by pptn. methods. Where all alk salts are present, they must be leached out with H_2O before percolation with the alc. salt soln. is begun.

C. R. F.

The determination of exchangeable calcium in carbonate-free soils. RICE WILLIAMS. Univ. College of N. Wales. *J. Agr. Sci.* 18, 439-45(1928).—The possibility of using HOAc as a reagent for extg. exchangeable Ca from CO_3 -free soils is discussed and exptl. results are presented showing that Ca is quantitatively pptd. from an HOAc medium. For the detn. of exchangeable Ca, 25 g. of soil (< 1 mm.) are treated in a beaker with 200 cc. of 0.5 N HOAc soln., stirred several times, allowed to stand at least 2 hrs., the supernatant liquid is poured into a filter and the filtrate collected in a 1000 cc. flask. The soil is then washed into the filter with 0.5 N HOAc and leached with the same (70 to 100 cc. at a time) until 1000 cc. of filtrate are collected. The CaO is estd. in 500 cc. of the leachings by treating with 5 cc. of concd. NH_4OH (d 0.88), 10 g. of NH_4Cl , and excess of $(\text{NH}_4)_2\text{C}_2\text{O}_4$ soln., vigorously stirring or boiling, letting stand over night, filtering off the pptd. CaC_2O_4 , dissolving the latter in dil. H_2SO_4 and titrating with standard KMnO_4 . The method gives results which check well with those by the Hissink NaCl method. Slightly higher values yielded generally by the latter may be attributed to very small quantities of Ca salts in the NaCl used. In the case of heavy clay soils it was found necessary to employ a 10 g. sample, instead of 25 g., and to wash by decantation, instead of leaching on a filter.

P. R. DAWSON

Treatment of soil for prevention of plant diseases. D. G. MILBRATH. Calif. State Dept. Agr., *Monthly Bull.* 18, 7-15(1929).—A review of the literature with 22 references appended.

C. R. F.

The effect of one element of plant food upon the absorption by plants of another element. J. F. BREAZEALE. *Ariz. Agr. Expt. Sta., Tech. Bull.* 19, 465-80(1928). The absorption of nutrient elements by the wheat plant was studied by the water culture method. NaNO_3 , K_2SO_4 and Na_2PO_4 were the resp. sources of the N, K and P in the nutrient solns. The amt. of adsorption was detd. by chem. examn. of the plants. Nitrate greatly stimulated absorption of K. At an early period of growth K is needed by the plant in a capacity similar to that of a catalyzer, and is much concerned in the translocation of the carbohydrates and in the building up of vegetative tissue. If N is available, much K may be necessary and it will be demanded by the plant; if N is not available, a small quantity of K will be demanded for the building up process and only enough will be absorbed for the other needs of the plant. Thus N may be the limiting factor in the absorption of K. The absorption of N from solns. by wheat seedlings was not affected by the presence of K, P or CaSO_4 . The absorption of P from solns. seems to be slightly increased by the presence of N, and diminished by an excess of CaSO_4 . The absorption of Ca does not seem to be affected by the presence of N, K or P. The absorption of K from solns. is increased by the presence of other plant foods, particularly N. The effect of N upon the absorption of K is carried over from 1 period when N is present, to another period when N is absent. This indicates that the effect is due, in part, to a demand within the tissues of the plant. This same phenomenon

is true in the effect of P and CaSO_4 upon the absorption of K. The effect of N upon the absorption of K seems to be manifested both within the tissues of the plant while the plant is not feeding and also during the act of absorption. This is shown by the more rapid absorption when solns. contg. N and K are mixed and the plant is grown half-time in this mixt. and half-time in distd. H_2O . The marked effect of N upon the absorption of K is closely correlated with a stimulated top growth and transpiration and not correlated with a stimulated root growth. C. R. F.

Factors affecting the iron and manganese content of plants with special reference to herbage causing "pinning" and "bush-sickness." W. GODDEN AND R. E. R. GRIMMETT. Rowett Research Inst., Aberdeen, and Dept. of Agr., N. Zealand. *J. Agr. Sci.* 18, 363-8(1928).—The malady of sheep called "pinning," as described by McGowan (*Scottish J. Agr.* 5, 274), has many points of similarity to the "bush-sickness" of N. Zealand. The latter has been shown by Aston (*C. A.* 19, 1320) to be assocd. with pasture of abnormally low Fe content. Comparative analyses of "pinning" and "bush-sick" soils show that the 2 have a similar mech. compn, both being sandy silts with a clay content of less than 3%. The former is higher in N, P and K, but lower in Ca. Pot expts. were conducted with "pinning soil," sand, and a local arabic soil to test the effects of lack of drainage, application of org. matter, application of Fe in various combinations, application of S (free or as FeSO_4) and application of lime on the Fe and Mn content of the crops (oats and mustard). In most cases the % of Fe was higher in mustard than in oats, while the reverse was true for Mn. In the sand cultures, S (either free or as SO_4) slightly increased the % of Mn in the crop. Lack of drainage increased the Mn content of oats approx. 6-fold and somewhat less in mustard. Water-logged and mildly reducing conditions apparently had more effect on Mn than on Fe in rendering it available. The addn. of 3% of clay to the sand had no definite effect on either Mn or Fe content of the crop. In the "pinning soil" the mustard failed to grow, possibly because of higher Fe requirement, and in the limed pot became markedly chlorotic before dying. The Fe content of the oats was fairly uniform throughout the series. Mn was much higher under undrained conditions, but the addn. of lime depressed it. Other treatments were without effect on either Fe or Mn. While the % of Fe in the crop was approx. the same as in the case of sand, the % of Mn was very much higher. In the local soil, both oats and mustard had a higher % of Fe than of Mn. Conclusion: On a given culture medium lack of drainage is the most potent factor in increasing the Mn content and Mn Fe ratio of the crop. Liming tends to decrease both of these. P. R. DAWSON

Certain soil properties in relation to sugar-beet growing. G. NEWLANDS. North of Scotland Coll. Agr. *Scottish J. Agr.* 11, 387-92(1928).—A study of a no. of Scottish soils indicated that poor growth of sugar beets is, in general, obtained when the p_{H} value of the soil falls below about 5.3. Poor growth is also usually obtained when the % of Ca sol. in dil. HCl is below about 0.12, or when the lime (CaCO_3) requirement is above 0.3%. These limits are affected by climatic conditions, type and mech. compn. of the soil, and other factors. K. D. JACOB

The significance of the soil solution for plants. S. P. KRAVKOV. *Sov. Gosud. Inst. Opytn. Agron. (Ann. State Inst. Expt. Agron. (Leningrad)* 4, 41-7(1926); *Expt. Sta. Record* 58, 614.-K discusses the following properties of the liquid phase of the soil system: (1) osmotic pressure; the influence of its increase or decrease on the growth of the plant, its part in the absorption of nutrients, the optimum pressure for normal growth, and methods of regulating the pressure; (2) the degree of electrolytic disson of the compds. which make up the soil soln.; (3) the H-ion concn. of the soil soln.; (4) stimulating substances; and (5) the quant. relationship among the nutrients found. H. L. D.

Barley laid and delayed in ripening owing to lack of phosphoric acid in the soil in consequence of smoke. E. G. DOERRELL. *Superphosphate* 2, 49-50(1929).—The low fertility of a plot of soil was traced to the indirect effect of smoke from railway engines and brown coal pits. The affected soil had p_{H} values of 4.1 to 4.3, while adjacent soils had the values 4.8 to 5.3. The affected soil also contained only 33% as much available P_2O_5 as the adjacent soils, as detd. by the Neubauer method. Laying of barley and delay in ripening was overcome by treating the affected soil with superphosphate. K. D. JACOB

Considerations on some soil and fertilizer problems in Ceylon. I, II. A. W. R. JOACHIM. *Trop. Agr. (Ceylon)* 69, 69-75, 133-40(1927); *Expt. Sta. Record* 58, 620.—The main factors affecting the Ceylonese and other tropical practice of scientific agriculture and soil management are summarized under the following headings: (1) fixation of atm. N in the soil and the use of legumes in increasing soil fertility, the

leaching of fertilizers from soils, the role of org. matter in plant nutrition in the tropics, the decompn. of org. matter in soil, the use of artificial farmyard manure and org. manure versus artificials; (2) the nature and importance of soil colloids, the soil moisture equil. as affected by colloids, absorption of fertilizers by soils, soil reaction—sourness and alky., pan and laterite formation, and the fertilizing of tropical crops. H. L. D.

The fertilizer triangle. FIRMAN E. BEAR. Ohio State Univ. *Ind. Eng. Chem.* 21, 382-5(1929).—The advantages of using the triangle diagram in plotting fertilizer ratio are discussed. Diagrams are shown on which are plotted fertilizer ratios adopted by regional conference for different sections of the country. J. J. SKINNER

Computation of no-filler fertilizer mixtures. A. B. BEAUMONT AND H. R. KNUDSEN. Mass. Agr. Coll. *Ind. Eng. Chem.* 21, 385-8(1929).—The recent addn. of a no. of coned. fertilizer materials to a constantly growing list of low- and medium-analysis org. and inorg. materials has made it easy to select the proper ingredients for no-filler mixts. of almost any grade. There is proposed a method for the computation of no filler mixts. based on the use of simultaneous algebraic equations contg. 2 or more unknowns. Various types of mixts. are discussed and methods for solving problems related to them suggested. Specific problems are presented and solved. The limitations and adaptations of certain classes of materials are pointed out. In general, single element components widen the ratio possibilities, and double-element components increase the no-filler possibilities. J. J. SKINNER

Nitrogen determination in cyanamide. STAN REYNAERT. Univ. Louvain. *Natuurw. Tijdschr.* 11, 27-8(1929).—N is detd. in fertilizers by the Kjeldahl method. It has been found that it is not necessary to heat until the mixture decolorizes—this would require 84 hours. A 6 hours' heating is sufficient. The results after short or long heating differ by only 0.01 to 0.03% N. ALBERT L. HENSEL

Lime for agricultural use. STAN REYNAERT. Univ. Louvain. *Natuurw. Tijdschr.* 11, 25-7(1929).—Lime is sold at different prices, according to empirical specifications and denominations. The prices are not proportional to the CaO content. If the detn. of the quantities required by a certain surface of soil, farmers often make mistakes, because they base their calcn. on the cost of the lime instead of the CaO content. ALBERT L. HENSEL

The significance of gypsum in agriculture. J. VITINS. *Z. Agrikulturchem.* 56, 298-9; *Chem. Zentr.* 1927, II, 1389. Gypsum is an important and cheap agent for preserving the fine particles of the soil in a crumbly structure. Its S is supposed to serve as a nutritive material on podsol soils. Gypsum is valuable for overcoming alkalinity in soils. G. SCHWACH

Preparation of potassium nitrate. A. L. MEHRING, WM. H. ROSS AND A. E. MERZ. Bur. of Chemistry & Soils, Wash., D. C. *Ind. Eng. Chem.* 21, 305-8(1929).—The advantages of KNO_3 as a fertilizer over other nitrates are discussed and various com. processes for its manuf. are reviewed. A preliminary rept. is given of a lab. study of the reactions involved in the conversion of KCl to KNO_3 by treatment with HNO_3 or NO_2 . J. J. SKINNER

Hygroscopicity of fertilizer materials and mixtures. J. R. ADAMS AND A. R. MEIER. Bur. of Chemistry and Soils, Wash., D. C. *Ind. Eng. Chem.* 21, 305-7(1929). The vapor pressures of satd. solns. of fertilizer salts have been detg. at intervals from 10° to 50° , and calcns. made of the relative humidities prevailing over the solns. The con. fertilizer salts, KNO_3 , NH_4 phosphate, and K phosphate, are among the least hygroscopic fertilizer salts. The hygroscopicity of a mixt. of fertilizer salts is, in general, greater than that of the more hygroscopic salt, though in some cases the hygroscopicity of the mixt. is less than that of the more hygroscopic salt. These detns. are of value in predicting the storage and handling qualities of fertilizer salt mixts. J. J. SKINNER

Hot fermentation process and artificial manure. G. RUSCHMANN. *Z. Spiritusind.* 51, 258-9, 266-7, 275-6, 284(1928); cf. *C. A.* 22, 3481; 23, 1205. —By closely following the Krantz process for the hot fermentation of manure there is no appreciable loss of easily oxidizable carbonaceous matter. Fermentation is stopped when the temp. reaches 70° . A. SCHULTZ

History and technic of the superphosphate industry. V. The superphosphate industry in Switzerland. ANON. *Superphosphate* 2, 41-5(1929); cf. *C. A.* 23, 661.

Some results secured in "top dressing" poor southeastern pasture land with phosphatic fertilizers. ARTHUR J. PERKINS. *J. Agr. S. Australia* 32, 11-24(1929). Analyses of soils and of crops are given in connection with the results of fertilization expts. M. S. ANDERSON

Nitrogen and carbon nutrition of plants. BORNEMANN. *Fortschritte Landw.* 3,

250-2(1928).—It is considered that plants are unable to utilize urea directly; the urea increases the activity of soil bacteria which, by producing more CO₂, increase assimilation by the plant.

B. C. A.

Annual report of the entomologist to Government, Punjab, Lyallpur, for the year 1925-26. R. L. CHOPRA. Rept. Operations Dept. Agr. Punjab, Year Ending June 30, 1926, I, Pt. II, 67-125(1928).—*Sugar cane pests*.—The ratoon crop of Yuba cane was more heavily attacked by cane aleurodidae (*Aleurolobus barodensis*) than the ordinary crop of the same variety, the total sugar and sucrose content suffering a serious loss. Sprays of tobacco infusion and of kerosene emulsion gave 83 to 87% mortality of adult aleurodidae. The nymphs were more resistant to sprays, the max. mortality being obtained with kerosene and naphthalene emulsions. Excellent control of *sugar cane mites* was obtained with lime-S sprays, but the eggs were not affected. *Fruit tree pests*.—Introduction of 0.5-1.5 g. KCN crystals into the stems of citrus trees gave 65 to 95% mortality of larvae of the citrus leaf miner (*Phyllocnistis citrella*) with comparatively little damage to the trees themselves. Perfect control of the larvae was obtained by fumigation with HCN. The results of expts. with various sprays for the control of *citrus psylla* and *mango-hoppers* are tabulated. Eucalyptus, clove and citronella oils gave the most promising results as attractant baits for various species of fruit flies. Complete control of insects in stored grain was obtained by fumigation with a min. dose of 42 g. Ca(CN)₂ per 100 cu. ft. for 18 hrs. Germination of wheat fumigated with Ca(CN)₂ at the rate of 2 g. per 1000 cc. for 3 hrs. was delayed somewhat as compared with that of untreated grain but the total final germination was not affected. Fumigation with excessive amts. of CS₂ and HCN did not greatly interfere with germination of wheat. Results of expts. with a wide variety of chemicals and insecticides for the control of white ant attacks on sugar cane, wheat and chillies are tabulated. Damage to buildings by white ants was prevented by treating the floors with 4% As solns. and covering with a layer of soil for a short time. The fraction of kerosene oil distg. between 158° and 184° was the best of a no. of substances experimented with as attractant baits for chironomid flies. The results of extensive expts. with various chemicals for the extermination of field rats and porcupines are tabulated. The rept. contains considerable information relating to expts. with various agr. poisons, which cannot be satisfactorily abstracted.

K. D. JACOB

Combating mites on Hevea nurseries. H. GONGGRIJP. Algemeen Proefstation A. V. R. O. S., Medan. Arch. Rubbercultuur 13, 79-89(1929). (In English 90-7).—Comparative expts. with S, Akar-Toeba ext. and Neoton for combating mites showed that the quickest and best results can be obtained with S sprayed by means of a Rebschwefler app. Moreover the cost of the S treatment was only 1/2-1/4 that of the other methods.

C. C. DAVIS

Bordeaux mixture in combination with arsenical sprays. WM. GOODWIN AND H. MARTIN. South-Eastern Agr. Coll., Wye, Kent. J. Agr. Sci. 18, 460-77(1928).—The interaction of Bordeaux mixt. with Pb arsenate and Ca arsenate was studied by an examn. of the effects produced when Ca(OH)₂ is added to the arsenical compds. and when CuSO₄ is added to the arsenical compds. and Ca(OH)₂. The nature of the interaction of Ca(OH)₂ and diplumbic H arsenate is shown to be most complex and to result in the complete decompn. of part of the Pb arsenate and the formation of basic Ca arsenates. There is no support to the view that CaCO₃ decomposes diplumbic H arsenate with the production of sol. As compds. When Pb arsenate, in water, is allowed to interact for long periods with excess of hydrated lime, the amt. of basic Ca arsenates formed is such that large quantities of As are brought into soln. by the action of CO₂. Under conditions where the Ca(OH)₂ is rapidly converted to CaCO₃, the amt. of As rendered sol. is slight. Conclusion: In actual spraying there is a definite reduction of the risk of As injury when hydrated lime is added to Pb arsenate and to Ca arsenate. When the conditions are such that the addn. of hydrated lime brings about a reduction of As injury, the use of an "equal-lime" Bordeaux mixt. congt. an equiv. amt. of Ca(OH)₂ will prove far more effective.

P. R. DAWSON

Oil spraying of plum and prune trees. T. D. URBANNS. Calif. State Dept. Agr., Monthly Bull. 18, 65-6(1929).—Quick-breaking oil emulsions for winter spraying consist of 3 to 7 gals. of oil emulsions per 100 gals. of H₂O, while crude oil emulsions for spring sprays may be as concd. as 12 gals. per 100 gals. of H₂O. Aside from a stimulating action on the tree itself, the most important use is in the control of scale insects, aphid eggs, brown mites, conker worms, moss and lichen growth.

C. R. F.

Comparative study of _____ in controlling the larvae of *Eudemis* and *Cochylis*.
CEL. BIRON. Rev. vit. 70, 25-7(1929); Prog. agr. vit. 91, [53], 635-7(1928).—The efficacy of various types _____

was studied by treating grape plots on June 25 and 26, 1928 and ascertaining the no. of punctured grapes per 100 clusters, 10 days after the treatment. The arsenicals used were (1) liquid Cu-lime arsenate composed of 1 part Pb arsenate paste, 2 parts CuSO_4 , 3 parts CaO ; (2) liquid Cu-lime arsenate composed 0.15 part dry Cu arsenate, 2 parts CuSO_4 , 3 parts CaO ; (3) powd. Cu arsenate; (4) powd. Na arsenate; (5) powd. Ca arsenate; (6) none. Arsenicals 1 and 2 are legalized sprays while 3 to 5 are prohibited in France. Since the no. of punctured grapes per 100 clusters can be considered as a measure of the efficacy of the particular type of spray, the no. of punctured, exposed and concealed grapes were counted and reported separately as follows: (1) 750 and 841; (2) 170 and 197; (3) 92 and 103; (4) 81 and 90; (5) 87 and 91; (6) 1012 and 1250. Conclusion: Dry, powd. sprays are much superior to liquid sprays in the control of the larvae of *Eudemis* and *Cochylis* but there is a health hazard attendant in their application. B. believes, however, that the enhanced efficiency of the dry spray warrants the introduction of special spraying equipment, including gloves and masks for the sprayers, which is at present commercially available. K. S. MARKLEY

The use of calcium cyanamide for preventing chestnut blight. L. PETRI. *Ed. reg. stazione patol. veget.* 1926, 135; *La conc.* 36, 42(1928).--A soln. of glucose and asparagine, a soln. of mineral salts, and a soln. of earth at the foot of a chestnut tree were treated with a weak CaCN_2 soln. With the 1st and 2nd, sterilized at a low or at high temp., a dose 1 part 1000 stopped the development of *Blepharospora cambicola*. The 3rd soln. required 2 parts 1000 and sterilizing at 100°. Doses of 1.5 parts 1000 had a decisive tonic action; 5 parts 1000 were not toxic; they were a source of available N for the fungus. By spreading 1-2 kg. CaCN_2 at the base of every healthy adult chestnut tree for a radius of 3-4 m. the blight can be prevented. R. SANSONE

Vapor pressures of fumigants. IV. Vapor pressure of nicotine. H. D. YOUNG AND O. A. NELSON. *Ind. Eng. Chem.* 21, 321-2(1929). The vapor pressure of nicotine has been detd. between 25° and 246.2°. The air satn. method was used up to 100° and the static method from this point to the b. p. Tables and curves are given. O. A. NELSON

Investigations on the interpretation of the stimulating action of Uspulun Universal on the coming up of seedlings. ANNELIESE NIETHAMMER. *Inst. f. Bot., Pflanz., Z. Pflanzenkrankh. u. Pflanzenschutz* 39, 120-2(1929), cf. *C. A.* 21, 115. A 0.25% soln. of Uspulun Universal, acting for 2 hrs., had a complete disinfectant effect on the 10 fungi and 10 bacteria tested. LAWRENCE P. MILLER

The toxic property of sulfur. ROBERT C. WILLIAMS AND H. C. YOUNG. *Ind. Eng. Chem.* 21, 359-62(1929). A study of the toxicity of S in its ordinary combinations and of products associated with it (H_2SO_4 , H_2SO_3 , polythionic acids) reveals that polythionic acids are most toxic to spores of "*S. cinerea*". Artificially oxidized sulfurs are effective in the control of "*V. inequalis*" provided the oxidizing agent does not destroy the polythionic acids. A. WHITE

Colorimetric determination of nitrates in soils (UMBERTO DE NARDO) 7. Potash from New Jersey greensands (THOENEN) 18. Future of the manufacture of oil from the skins of pressed grapes [ash as fertilizer] (MONTERO) 27. The formation of red soil and of black vlei soil from dolerite (MAUFER) 8. Fertilizer. I. G. FARBENIND. A.-G. Brit. 295,477, June 25, 1927. In prepr. mixed fertilizer, KCl is converted into K_2SiF_6 , the latter is decomposed by aq. NH_3 , the mixed soln. of KF and NH_4F is treated with mono- or di-Ca phosphate or with a phosphate soln. obtained by treating crude or other phosphates with HNO_3 or HNO_2 together with H_2SO_4 (suitably after removal of a portion of the H_3PO_4), the CaF_2 is

filtered out, and the fertilizer is recovered from the filtrate. Various details and modifications of procedure are described. Cf. C. A. 23, 1984.

Fertilizers. I. G. FARBENIND. A.-G. Brit. 295,825, Aug. 5, 1927. A readily spreadable mixed fertilizer is prepd. by mixing an NH_4NO_3 soln. contg at least 92% NH_4NO_3 and heated sufficiently to keep it liquid, with solid fertilizer salts such as KCl or $(\text{NH}_4)_2\text{SO}_4$.

Phosphate fertilizers. F. L. SCHMIDT. Brit. 296,022, Aug. 23, 1927. A mineral phosphate is rendered citrate-sol. by roasting (suitably at $800\text{--}1300^\circ$) with K_2CO_3 obtained from K Mg bicarbonate (details of the manuf. and use of which are described).

Non-hygroscopic phosphatic fertilizer. HENRY BLUMENBERG, JR. (to Stockholders Syndicate). U. S. 1,706,101, March 19. Crude ground phosphate rock is mixed with H_3PO_4 in excess, using sufficient H_3PO_4 to convert the phosphate rock to acid Ca phosphate and leave an excess of 20% H_3PO_4 as compared with the quantity of acid Ca phosphate formed, and the mass is fused by heating to 600° and the product is ground.

Treating seeds to destroy bacteria, etc. AUGUST KLAGES. U. S. 1,706,695, March 26. The complex Hg compd. salt obtained by the action of HgCl_2 on aniline-HCl or dimethylaniline-HCl in aq. soln. is used together with an alkali metal chloride.

Emulsified sulfur. ALBERT HARTZELL and FRANK H. LATHROP (to Walter C. O'Kane and Paul Moore, trustees of the Crop Protection Institute). U. S. 1,705,862, March 19. An emulsified S compn. suitable for insecticidal and fungicidal use is formed from S dissolved in naphthalene as a distributing agent and emulsified with a soap soln.

16—THE FERMENTATION INDUSTRIES

C. N. FREY

Butyric acid fermentation. A. HEIDUSCHKA AND CH. REYMANN. Tech. Hochschule Dresden. *Pharm. Zentralhalle* 70, 87-92(1929).—A systematic study of the conditions obtaining in the production of butyric acid by fermentation in connection with the various analytical methods for control of the resulting acids (butyric, lactic, acetic). W. O. E.

The lime-pressure method of preparing absolute alcohol. OTTO VON KEUSZLER. *Chem. App.* 16, 33-5(1929); cf. C. A. 23, 234.—The advantages of working under pressure are: the entire charge is recovered as abs. alc.; a charge requires 10 instead of 48 hrs.; the steam consumption is reduced 75%; the resulting lime residue is easy to handle; the alc. is completely anhyd.; the loss is about 2%, against 5-8% by the lime method without pressure. App. for producing 6000 l. daily is shown. Cf. C. A. 21, 3251. J. H. MOORE

Estimating heat consumed in batch rectification of alcohol. GLEN S. HOUGHLAND. *Chem. Met. Eng.* 36, 89-91(1929).—A method has been evolved for detg. the av. theoretical heat consumption for intermittent rectification in app. of the type described. The method has been applied to the concn. of EtOH from H_2O solns. having initial concn. of 1-20% and yielding a distillate of 92-46% alc., the residue being exhausted to 0.1% alc., columns of 9-16 perfect plates and also of an infinite no. of perfect plates. To det. the heat consumption applying to a given wt. of distillate passed over, the compn. and residue in the kettle must be known. The wt. and compn. of the initial charge and the wt. and compn. of the distillate, therefore, must be detd. The following equation is applicable if the small residue of liquid in the column is disregarded: $w_1 = (w_0 H_0 - dD) / (H_0 - D)$, where H_0 = initial wt. of charge, w_0 = initial concn. of alc. in charge, w_1 = concn. of alc. in residue left in kettle, D = wt. of distillate produced, d = concn. of alc. in distillate. The theoretical heat quantities involved at the instant when a given wt. of distillate has passed over may then be calcd. by known methods (Lewis, C. A. 16, 2561). The instantaneous heat values used in the data presented were plotted from Table 13, Principles and Practice of Industrial Distillation by E. Hausbrand. The heat values so obtained were supplemented by additional values which were obtained by plotting the data from the table in a different manner. C. N. FREY

A discussion of the microflora of alcoholic fermentation. J. WILLE. *Mikro-kosmos* 22, 73-8(1928).—Fermentation is a complex process and is the result of enzymes produced by living cells. Alc. fermentation yields 48.4% alc., 46.6 CO_2 , 3.3 glycerol, 0.6 CH_3COCOOH , 1.1 fusel oils. A description of the characteristics of top and bottom yeast is given. "Wild" yeasts and Kahlm yeasts are discussed. *Mycoderma variabilis* does not contain invertase, and cannot ferment cane sugar, maltose, dextrin, raffinose,

lactose or inulin. *Schizosaccharomyces pombe* is distinguished by its power to ferment dextrins, all natural sugars except lactose and produces 15.5 alc. by vol. Two species of acetic acid bacteria, *B. orleanense* and *B. xylinum*, are described. C. N. FREY

Occurrence, detection and determination of lauric acid in alcoholic beverages. J. GROSSFELD AND A. MIERMEISTER. Staatlichen Nahr.-Untersuchungsanstalt., Berlin. *Z. Untersuch. Lebensm.* 56, 167-87(1928).—For the detn. of lauric acid, 500 cc. of the sample and 300 cc. of H_2O are distd. and the distillate (450 cc.), together with the 50 cc. of EtOH used to wash out the condenser, is boiled under a reflux condenser for 30 mins. with 5 cc. of a 75% soln. of KOH. The soln. is evapd. and the residue dissolved in 25 cc. of a soln. of 25 g. of $NaC_2H_3O_2$, 5 cc. of glacial AcOH and 1 cc. of 1% phenolphthalein soln. in 250 cc. of H_2O . Then 30% AcOH is added until only a faint color remains, which is then removed by 1 drop of acetate soln. and restored by the addn. of 0.1 N NaOH soln. After filtration in the presence of diatomaceous earth, the soln. is boiled, 5 cc. of the $MgSO_4$ soln. added and any red color again dispersed by the acetate soln. After 24 hrs. the ppt. is filtered on a Gooch crucible previously washed with a little Mg laurate soln., and dried in a steam oven, washed, gently heated and the crucible reweighed. The loss in wt. gives the lauric anhydride, which, multiplied by the factor 1.105, gives Mg laurate. After correction for the soly. of the salt (0.5-0.6 mg. according to vol.), the use of the factor 0.9472 gives lauric acid. Qualitatively 0.2 mg. of lauric acid may be detected in the presence of myristic acid or 3 mg. of caproic acid. The caprylic acid value is detd. by the addn. of 1 cc. of a 50% soln. of KOH to the distillate (95 cc.) from a 100 cc. sample. The mixt. is boiled under a reflux condenser for 30 mins., evapd. to dryness, the residue dissolved in 10 cc. H_2O , neutralized to phenolphthalein with 30% AcOH, dild. with 50 cc. of H_2O , and 25 cc. of a 1.5% soln. of $Mg SO_4$ added. After 24 hrs. the soln. is filtered, 10 cc. of a soln. of 50 g. $NaC_2H_3O_2$, 3.12 g. $CuSO_4$ and 5 cc. of 20% AcOH per l. added, and the ppt. filtered off, dried and weighed on a Gooch crucible. The soly. correction is 0.7 mg. calcd. as Cu laurate, and the factor 0.869 then gives the caprylic acid value in cc. of 0.1 N acid. The principal esters of the so-called grape or cognac oils are those of lauric instead of capric acid. The EtOH content of a beverage did not affect its lauric acid content. The acid may be removed from fusel oils by rectification and is obtained largely in the second runnings during distn. C. R. I.

The fermentation method of preparing glycerol. J. PENKOVSKI. *Chem. Tisloversicht* 53, 7(1929); *Listy Cukrovar. Rozhledy* 6(1929).—The sirup from sugar beets is diluted with an equal quantity of H_2O , boiled 1 hr. with the addn. of powd. peat and diluted to a sp. gr. 10-12° B $_6$. Nutritive salts, NH_4 , P_2O_5 , Ca, etc., are added together with yeast which is added in the amt. of 5% of the sugar in the sirup. The fermentation is conducted in an alk. medium in the presence of Na_2SO_4 , Ca and Mn salts. After 36-48 hrs. the EtOH and AcH are distd. off; the SO_4 is pptd. with Ca salts; after filtering, the ferment is neutralized with CO_2 and SO_2 and refiltered. The crude glycerol is concd. and then distd. in a vacuum with superheated steam. The yield shows: glycerol 20%, EtOH 17.5% and AcH 8%. The quality of EtOH is poorer than that from potato mash. •

Industrial applications of invertase. Fermentation of molasses with invertase. M. C. BASINI. *Zymol. chim. col. zuccheri*, 3, No. 3, 105-7(1928).—In prep. alc. by the sucrase process, molasses is treated with 2 parts per 1000 of NaF and 1-2.5 g. H_2SO_4 per l., boiled in a glass flask to evap. volatile fatty acids, sterilized in an autoclave for 20 mins., cooled and pure beer yeast is added to invert the sucrose. The inverted sugar then ferments. After 36-48 hrs. at 28-30° the contents of the flask are introduced into a mixt. in a fermentation app. of 1-2 l. From this, after fermentation, the mixt. is passed into tubs of 1000 l. and later into the mother yeast vat of 10,000 l. and finally into large fermentation vats of 30,000 l. The fermented mixt. is filtered and distd. A 10% saccharose soln. gave a weak inversion in the cold with 2.5 g. H_2SO_4 per l. Better results were obtained with more acid, or by warming. The H_2SO_4 acts indirectly, liberating organic acids with a weaker action on the sucrose, on which salts have an unfavorable influence. A min. inversion also follows with much H_2SO_4 . The inversion of sucrose is therefore detd. by the yeast invertase, the action of which is retarded by the mineral substances in the molasses. The enzyme must be acclimated to the medium in which it works; the resistance of the invertase is decreased by rapid passage from one medium to another. Acidity and high contents of sugar influence unfavorably the fermentation. If the mixt. is too concd., much alc. is produced at once, slowing the inversion. If the mixt. is too acid other noxious enzymes develop and fermentation is arrested before all the sugar is transformed. R. SANSONE

Analytical characterization of fermentation vinegar. L. A. JANKE AND F. POP-

BERGER. *Deutsche Essigind.* 31, 257-9, 265-7(1927).—Fermentation vinegar may be distinguished from dil. spirit vinegar by detn. of its I value (mg. of I required to react with that amt. of the original substance which contains 10 g. AcOH), which at 40° should be at least 50. A sample (about 40 cc.) is evapd. to approx. $\frac{1}{4}$ of its vol. and made up again to its original vol. To 10 cc. of this soln. are added 40 cc. of 0.01 N I and 8 cc. of 2 N NaOH more than are required for neutralization, and the whole is then warmed to 40°. After 2 hrs. 2 N HCl is added (4 cc. more than the vol. of NaOH previously required), and 8 mins. later the liquid is titrated with 0.01 N $\text{Na}_2\text{S}_2\text{O}_3$. Admixt. of fermentation vinegar cannot be detd. unless the I value is known. Filtration of the fermentation vinegar through wood charcoal lowers the I value because of the adsorption of a portion of the I-reacting constituents, which appear to be related to vitamin D.

B. C. A.

The future of the vinegar industry presents varied problems. A. E. ROWSE, JR. *Fruit Products J. and Am. Vinegar Ind.* 8, No. 7, 28-9(1929).

J. A. KENNEDY

The preparation, composition and classification of Samos wines. A. KICKTON AND P. BERG. Hyg. Staatsinstitut, Hamburg. *Z. Untersuch. Lebensm.* 56, 397-422 (1928).—Complete exams of 442 samples showed an av. EtOH content of 13-14% with wide variations, total solids 21-24%, titratable acidity 0.28-0.42%, sugar-free ext. 1.7-2.5%.

C. R. F.

The treatment of "mousy" wines with the Siemens ozonizer. ERICH WALTER. Inst. Gärungsgewerbe Berlin Korr. *Abt. Trinkbranntwein-Likorfabrikat.* 17, 20-1; *Chem. Zentr.* 1927, II, 1211.—Two wines treated with the ozonizer lost their disagreeable taste, which did not reappear afterwards. Also certain kinds of carbon are recommended for removing the "mousy" taste. In 1 expt., the disagreeable taste was removed, but at the same time also the coloring matter of the wine disappeared completely.

G. SCHWOCH

The examination and evaluation of wine brandies and distillates. G. BUTTNER AND A. MIERMEISTER. Staatlichen Nahr-Untersuchungsanstalt. Berlin. *Z. Untersuch. Lebensm.* 56, 492-8(1928).—Complete analytical data on 55 samples are presented in tabular form.

C. R. F.

New conceptions for brandy. CURT LUCKOW. *Deutsche Essigind.* 33, 26-8 (1929).—A discussion of certain tentative definitions for brandies and spirits during a meeting of the Ger. Food Manufacturers' and Dealers' Assocn.

W. O. E.

The extractives of brandy. WILLIAM PARTRIDGE. *Analyst* 54, 154-5(1929).—The 4th edition of *Aids in the Analysis of Foods and Drugs* states that the total solids of brandy are "about 1%." Since 1925, brandies usually contain less.

W. T. H.

Influence of various yeast-races and temperatures on fermentation and quality of beer. R. HORCH AND SCHULTEIS. *Wochschr. Brau.* 45, 394-8(1928).—The best quality of beer was produced at a pitching temp. of about 4° and a max. during fermentation of 7-8°. Since a powdery yeast has a higher fermenting power than a normally flocculated yeast it is suggested that the quality of the beer might be improved by adding the former toward the end of a fermentation to induce a strong secondary fermentation.

A. SCHULTZ

Extraction of sugar from grapevine prunings (CARRIÈRE) 28. Separating H and CO_2 [as in fermentation gas] (U. S. pat. 1,700,707) 18.

DEHNICKE, JOHANNES: *Laboratoriumsbücher für die chemische und verwandte Industrien.* Bd. XXVI. *Laboratoriumsbuch für die Brennerei-industrie.* Halle (Saale): W. Knapp. 392 pp.

Fermentation of sugars. P. LINDNER. *Brit.* 295,648, Aug. 16, 1927. Sucrose, glucose and fructose are fermented with production of CO_2 , alc. and lactic acid by use of a single kind of bacterium such as *termobacterium mobile* occurring in the aguamiel of the *lague americana*. The ferment may be prepd. by introducing the bacterium in sterilized milk with the addn. of sucrose, glucose or fructose. Fruit juices or plant exts. contg. any of these sugars may be fermented to produce a sparkling alc. and slightly lactic beverage. The bacteria may be used in bread making.

Waste waters from distilleries. RENÉ L. SALMON. *Fr.* 646,655, Dec. 31, 1927. An app. is described in which waste waters from distilleries may be vaporized for the production of utilisable steam with recovery of the waste products, particularly glycerol.

17—PHARMACEUTICAL CHEMISTRY

W. O. EMERY

Analysis of fluidextract of ergot. H. KAUL. *Süddeut. Apoth.-Ztg.* **68**, 195 (1928).—For the detn. of the total bases, the ext. (40 g.) is shaken with magnesia (2 g.) and a mixt. of equal parts of xylene and chloroform (40 cc.). After some time 7 g. of powdered tragacanth is added; 25 cc. of the filtered solvent is mixed with 20 cc. of 0.1 N HCl and sepd.; the acid soln. is titrated with 0.1 N KOH soln. with methyl orange. B. C. A.

Examination of extracts, etc., containing fat and mucilage. J. HÜBSCHER. *Süddeut. Apoth.-Ztg.* **68**, 205-6 (1928).—For the examn. of cod-liver oil and malt exts. the material is mixed with hot water, and boiled after addn. of concd. HCl; after cooling, the liquid is shaken with ether, and the emulsion sepd. by addn. of NaCl. The acid is washed out with water, and the ether evaporated. The residue, contg. traga anth, mucilage and cod-liver oil, is warmed for some time, dehydrated with Na_2SO_4 and treated with ether. B. C. A.

Sodium arsenite solution. W. MEYER. *Süddeut. Apoth.-Ztg.* **68**, 226-7 (1928).—The method for the analysis of the soln. of Na arsenite and hydroxide of the German pharmacopeia (6th ed.) is criticized. B. C. A.

Determination of bismuth in substances used in the treatment of syphilis. BOUILLÉNE AND M. DUMONT. *Compt rend. soc. biol.* **98**, 879-80 (1923). A microchem. method depending on the color reaction of Bi salts in the presence of KI is described. B. C. A.

Cedrol; its source and derivation. FRANK RABAK. *Am. Perfumer* **23**, 727-8 (1929).—In order to verify the conclusion that cedrol is a normal constituent of fresh cedar wood rather than of the old seasoned or weathered wood, test distns. were carried out with sawdust obtained from fresh cedar logs. Samples of oil were taken at intervals of 15, 30, 45, 60, 90 and 120 mins. All became more or less semi solid after standing 2 days through sepn. of cryst. cedrol. A composite sample of the oils contained 12.5% cedrol. The oil remaining after sepn. of the cedrol possessed properties similar to the cedar-wood oils of commerce, which are usually products obtained by distg. the waste sawdust and shavings that result from the manuf. of pencil slats made from old cedar fence rails. Comparing the chem. and phys. properties of cedar-wood oil from both fresh and old wood, the following values were obtained, resp., d_{20} 0.9623, 0.9606; n_D^{20} 1.5050, 1.5020; $[\alpha]$ -25.8°, -52.1°, soly in 95% alc. all proportions, 1 part in 5.5 vols.; acid no. 1.25, 0.26, ester no. 2.67, 0.87; Ac no. 38.6, 13.03, as acetate 1.25, 0.47%; combined cedrol 1.05, 0.40%; free cedrol 14.71, 4.80%; total cedrol 15.76, 5.20%. Two distinct sources for the production of cryst. cedrol are available: fresh cedar waste as also the drying kilns where great quantities of cedar lumber are annually treated. W. O. E.

Evaluation of D. A.-B. VI. Salves. W. BRANDRUP. *Apoth. Ztg.* **44**, 149 (1929).—Quant. procedures are suggested for detg. H_2BO_3 and Zn in the official Ger. prepn. Ung. acidi borici and Ung. zinci, resp. W. O. E.

Alkaloids of some Indian aconites. II. Pseudoaconitine. THOMAS M. SHARP. *J. Chem. Soc.*, Dec., 1928, 3084-106; cf. C. A. **22**, 3167. Most species of *Aconitum* so far examd. chemically contain alkaloids, each species in general yielding a different alkaloid. Pseudoaconitine has, however, been obtained from 2 species, *A. denser rhizum* and *A. balfourii*. These alkaloids may be divided in to the toxic (aconitine), and non toxic (atisine) types. With the exception of lycaconitine and kappa conitine, all alkaloids of the former type are similar in that they are all diacyl esters of other bases generically called aconines, which have in common Ac as one of the groups present. Aconitine is acetylbenzoylaconine. On heating aconitine in a sealed tube with MeOH, the Ac is replaced by the Me group, resulting in the formation of methylbenzoylaconine. Again, when the dry base is heated slightly above its m. p., one mol. of AcOH is split off and a new base, pyraconitine, is formed. It was thought that a careful study of these 2 reactions as applied to pseudoaconitine might throw some light on the relative position of the groups believed to be present in this alkaloid, i. e., $\text{C}_{19}\text{H}_{21} \left\{ \begin{array}{l} (\text{OCH}_3)_4(\text{CHOH})(\text{NCH}_3)(\text{OH})(\text{OCOCH}_3) \\ \text{OCOC}_6\text{H}_5(\text{OCH}_3)_2 \end{array} \right.$, and that it

might contain some weakened link affording a useful point of attack by oxidation or other degradation process. It is now shown that when pseudoaconitine is heated in a sealed tube with MeOH, the Ac is replaced by Me, the same reaction taking place but more slowly when the base is boiled with the alc. under reflux. A similar reaction also

takes place when tetracetylpsudaconine is treated with either MeOH or EtOH, only one of the Ac groups being replaced by the Me or Et group, the latter being introduced at a much slower rate. It is evident, therefore, that there is some group present in a particular relation to this Ac which facilitates the replacement. In an attempt to find such a group, a no. of Ac derivs. of comparatively simple structure were prepd. and treated with MeOH in the above indicated manner, but so far without success. The Ac group or groups in AcOPh, diacetylpyrocatechol, diacetylresorcinol, diacetylquinol, triacetylpyrogallol, acetylsalicylic acid, acetylpropenylguaiaicol, acetyleugenol, acetyl-isoeugenol, acetylcyclohexanol, pentacetylmethylinositol, and hexacetylmannitol are all unaffected in this way. On heating psudaconitine above its m. p. it loses AcOH with the formation of pyropseudoconitine, which has now been obtained in cryst. form. The presence of 2 OH groups in psudaconitine has already been previously indicated indirectly, and now directly by the formation of a diacetyl deriv., a fact showing that in the removal of AcOH none of the OH groups is involved. Tetracetylpsudaconine, which contains no free OH, loses 1 mol. of AcOH on heating, with the formation of triacetylpyropseudoconitine, and this on hydrolysis yields pyropseudoconitine, identical with the base obtained on hydrolysis of pyropseudoconitine. The latter yields, moreover, on acetylation a compd. contg. 3 Ac groups but has only 5 MeO groups, whereas pyropseudoconitine has 6. Analysis leaves no doubt that the substance has been formed by the acetylation of the 2 OH groups and by the replacement of 1 Me by an Ac group. The acconine obtained on hydrolysis of this substance is quite different from that obtained from pyropseudoconitine and triacetylpyropseudoconitine in that all attempts at crystn. have failed, while the base from other sources crystallizes readily. In view of the resistance of pyropseudoconitine to catalytic reduction by H, it is probable that the loss of AcOH takes place between the Ac group and an H atom attached to a remote C leading to the formation of a bridge linkage. The C in question would thus become asymmetric, a view receiving support from the specific rotations of pyropseudoconitine and triacetylpyropseudoconitine, which are much greater than those of the bases from which they are derived. The following compds. were prepd. and characterized for purposes of the present investigation: *Pyropseudoconitine*, $C_{21}H_{21}O_5N$, m. 132.5°, $[\alpha]_D^{16}$ 175.2° ($c = 1.154$ in alc.), is very sol. in the usual org. solvents, does not react with MeI, is hydrolyzed by alc. KOH to *pyropseudoconitine*, $C_{21}H_{23}O_5N$, m. 172°, $[\alpha]_D^{16}$ 227.5° ($c = 1.217$ in alc.); *triacetylpyropseudoconitine*, $C_{24}H_{25}O_8N$, m. 228°, $[\alpha]_D^{16}$ 284° ($c = 0.537$ in $CHCl_3$), yields on hydrolysis *dimethylpyropseudoconitine*, $C_{21}H_{25}O_5N$; *triacetylpyropseudoconitine*, $C_{24}H_{25}O_8N$, m. 155.8°, $[\alpha]_D^{16}$ 156.4° ($c = 1.202$ in alc.); *veratroylpsudaconine*, *HBr-salt*, $C_{28}H_{31}O_{11}N \cdot HBr \cdot H_2O$, m. 237.8°, $[\alpha]_D^{16}$ 2.15° ($c = 2.09$ in H_2O), yields the base, $C_{28}H_{33}O_{11}N$, m. 206.7°, $[\alpha]_D^{16}$ 29.8° ($c = 1.12$ in alc.); *HCl-salt*, m. 249-50°; *monoacetylveratroylpsudaconine perchlorate*, $C_{29}H_{33}O_{12}N \cdot HClO_4$, m. 240-2°; *triacetyl-methylpsudaconine*, $C_{22}H_{25}O_8N$, m. 280.2°, $[\alpha]_D^{16}$ 18.5° ($c = 0.766$ in alc.); *triacetyl-ethylpsudaconine*, $C_{23}H_{27}O_8N$, m. 171°, $[\alpha]_D^{16}$ 26° ($c = 0.98$ in alc.); *monobenzoylepsudaconitine perchlorate*, $C_{29}H_{27}O_{12}N \cdot HClO_4$, m. 236°; *diacetylpsudaconitine*, $C_{20}H_{23}O_8N$, m. 229°, $[\alpha]_D^{16}$ 24° ($c = 1.00$ in $CHCl_3$); *monoacetylpsudaconitine perchlorate*, $C_{20}H_{23}O_9N \cdot HClO_4$, amorphous.

W. O. E.

Preparation of mercury stearate, palmitate and oleate. G. FRIEDLANDER. Univ. Breslau. *Apoth. Ztg.* 44, 167-8 (1929). Methods for prep. these salts for use in salves, unguents, etc., are described.

W. O. E.

Comparative methods for the estimation of alcohol in tinctures. K. HERING. *Apoth. Ztg.* 44, 180-4 (1929).—In the present study about 150 alc. detus. were carried out to ascertain the procedure best suited to the purpose. It developed that contrary to the expectation of finding the Swiss procedure the most exact and advantageous the official Ger. Pharm. method with some minor modifications of the author proved entirely satisfactory in point of rapidity, simplicity and accuracy. Three types of app. used in these expts. are illustrated.

W. O. E.

Pulmonal. C. A. ROJAHN AND MAX HERTER. Univ. Halle-Wittenberg. *Apoth. Ztg.* 44, 211-2 (1929).—A liquid prepn. for colds, coughs, etc., appears to have the following compn.: succus liquiritiae and other exts. 5, sucrose 7, alc. 2, Na salicylate 0.3, water 85% together with small quantities of anis oil and menthol.

W. O. E.

Detection of hydrogen peroxide with potassium permanganate via the D. A.-B. 6. G. FRERICHS. *Apoth. Ztg.* 44, 225-6 (1929).—A discussion of the official Ger. procedure.

German Pharm. standards for salve fats and oils. RICHARD EHRENSTEIN. *Apoth. Ztg.* 44, 197-8 (1929).—A tabulated compilation of standards for fats and oils specified by the D. A.-B. 6, together with a commentary thereon.

W. O. E.

Preparation of morphine and its most important derivatives. F. CHEMNITZ. *Pharm. Zentralhalle* 70, 101-4(1929).—The procedures treated in the present paper involve the prepn. of morphine, diacetylmorphine, apomorphine, codeine and ethyl morphine. W. O. E.

Detection of certain drugs by means of the Griebel microbeaker method. F. WEISS. *Apoth. Ztg.* 44, 237-40(1929).—The detection of certain volatile substances like CH_3O , MeCHO , AcMe , BzMe , hexamethylenetetramine, paraldehyde, amylene hydrate and lobeline, by means of *m*- or *p*-nitrophenylhydrazine as reagent is described, in connection with the type of app. used, and the form of crystals obtained with formaldehyde and acetaldehyde, acetone and acetophenone. W. O. E.

Rheumatism preparations. C. A. ROJAHN AND RUDOLF SEIFERT. Univ. Halle-Wittenberg. *Apoth. Ztg.* 44, 251-2(1929).—Two preps. were examd.; *Doloresum liniment* contained salicylic acid 0.6, Me salicylate 6, mustard oil 0.5, oil turpentine 6, CHCl_3 12, menthol 0.6%. *Tophiment* consisted essentially of NH_3 1.53, salicylic acid (fixed) 5.9, thiosinamine (calcd. to mustard oil) 0.43, turpentine oil and menthol 5.95, CHCl_3 10, fatty acids 1.26, mineral oils 7.34, phenylcinchoninic acid (as NH_4 salt) about 4.5%. W. O. E.

Iodex. C. A. ROJAHN AND WILHELM KLAUDITZ. Univ. Halle-Wittenberg. *Apoth. Ztg.* 44, 294(1929).—A description of a salve having a base of about $\frac{3}{4}$ vaseline and $\frac{1}{4}$ iodized fats, the latter with a total I content of about 4%, of which about 0.7% consists of free I. W. O. E.

Application of fluorescence in pharmacy. RICHARD WASICKY. *Pharm. Monatsh.* 10, 17-8(1929).—In the present discussion reference is made to certain classical examples of fluorescence in drugs and the manner of applying this behavior in their identification. W. O. E.

Estimation of ascaridole in oil of chenopodium. E. KNAFFL-LENZ AND A. HOPMANN. Univ. Wien. *Arch. Pharm.* 267, 117-28(1929).—The results of the present study show that a biol. evaluation is impossible; that the color reactions arising from the interaction of ascaridole with phenolphthalein, dimethylaminobenzaldehyde etc., are unsuited to a quant. estn., since a strict control of exptl. conditions surrounding oils of low ascaridole content is out of the question. Of the oxidimetric methods that of Paget involving TiCl_3 and an empirical factor yields good reproducible values. The reason why only a fraction of the theoretically possible quantity of TiCl_3 is consumed is seen in the action of HCl on ascaridole in the reaction mixt. An iodimetric estn. does not appear to be possible since ascaridole reacts violently with the pptd. I. The intensity of the brown coloration arising from the action of concd. HCl on 1% alc. solns. of the oils after some hrs. is proportional to the ascaridole content. If such coloration be compared with others produced by standards of known ascaridole content, an estn. may be effected accurately within a few percent. The phys. consts., as d., $[\alpha]$ and n_D can serve only in oils of like source and prepn., otherwise the $[\alpha]$ will show variations of several degrees, while the d. in unsophisticated samples will be approx. proportional to the ascaridole content. W. O. E.

Evaluation of bismuth oxyiodide. G. BÖMMING AND K. FERREIN. Berlin-Brütz. *Arch. Pharm.* 267, 142(1929).—A commentary on the method of evaluating this official Ger. prepn. with suggestions for improvement. W. O. E.

Pharmacological evaluation of digitalis preparations. C. FOCKE. *Arch. Pharm.* 267, 169-77(1929).—Of 4 preps. of Ger. manif. found in a Swedish apothecary and believed to be under strength, all proved on later examn. to be of standard strength. It is shown that certain digitalis preps. contg. glycerol are more slowly resorbed by the frog lymph sack than when free from this vehicle. An official evaluation of all such preps. is scarcely feasible on account of its magnitude; such control should rather be left to the producing firms whose greatest interest must be to maintain the highest standards. An improvement in the labeling might well be introduced, such as an indication of the date on which the package was filled. W. O. E.

Estimation of brucine as silicotungstate, and analysis of semen strychni. B. KLIATSHKINA AND M. STRUGADSKII. Chem.-Pharm. Forschungsinst. Moskau. *Arch. Pharm.* 267, 177-92(1929); cf. C. A. 22, 1213.—The results are given in a series of tables, and may also be expressed as follows: The ppt. of brucine silicotungstate has no const. stoichiometric compn. The mol. proportion between alkaloid and complex acid can vary from 4:1 to 1.5:1. The compn. of this ppt. is dependent upon the following 3 factors: (a) the acid or salt content of the soln., (b) the amt. of reagent used in pptn., (c) the pptn. temp. Both gravimetric and volumetric procedures are given in great detail. W. O. E.

Synthetic drug studies. IV. Synthesis of sulfur-containing preparations. H.

P. KAUFMANN AND E. WEBER. Univ. Jena. *Arch. Pharm.* 267, 192-211(1929).—An exptl. study confined mainly to the introduction of the SCN group into, and the influence of such groups, on certain antipyretics (aniline, phenetidine and phenylhydrazine) and disinfectants (thymol, cresols and hydroxyquinolines). The method of introducing SCN into the above compds. involves treatment in a suitable solvent with NaSCN and Br. Among the new compds. prepd. and characterized were the following: *p*-rhodanacetanilide, $C_8H_8ON_2S$, needles m. 188°; 1-amino-2-rhodan-4-ethoxybenzene, $C_8H_8ON_2S$, silky needles m. 67-8°, easily convertible to 2-amino-6-ethoxybenzthiazol; $C_8H_8ON_2S$, needles m. 161°; 2-diacetylamino-6-ethoxybenzthiazol, $C_{13}H_{14}O_3N_2S$, m. 245°; bis(1-amino-4-ethoxy)2-disulfide, $C_{16}H_{20}O_2N_2S_2$, m. 101°; sym-formyl-(*p*-rhodanphenyl)hydrazine, $C_8H_8ON_2S$, needles m. 132°; sym-Ac(*p*-rhodanphenyl), $C_8H_8ON_2S$, m. 171°; sym-benzoyl-(*p*-rhodanphenyl)hydrazine, $C_{14}H_{11}ON_2S$, m. 164°; sym-phthalyl-(*p*-rhodanphenyl)hydrazine, $C_{16}H_9O_2N_2S$, m. 213°; sym-acetyl-bis(*p*-rhodanphenyl)hydrazine, $C_{16}H_{11}ON_2S_2$, needles m. 160°; sym-benzoyl-bis(*p*-rhodanphenyl)hydrazine, $C_{21}H_{14}ON_2S_2$, m. 160°; α -hydroxy- γ -rhodanquinoline (4-rhodancarbostyryle), $C_{10}H_8ON_2S$, yellowish needles m. 141°; γ -rhodan- α -hydroxyquinoline, $C_{10}H_8ON_2S$, m. 134°; 1-methyl-4-isopropyl-3-hydroxy-6-rhodanbenzene (3-methyl-4-rhodan-6-isopropylphenol), needles m. 105°; 1-methyl-2-hydroxy-5-rhodanbenzene (*o*-methyl-*p*-rhodanphenol), C_8H_7ONS , m. 71°; 1-methyl-3-hydroxy-5-rhodanbenzene (*o*-methyl-*m*-rhodanphenol), C_8H_7ONS , needles m. 76°; 1-methyl-4-hydroxy-3-rhodanbenzene, C_8H_7ONS , m. 105°, yields with alc. HCl a *N*-free compd., $C_8H_6O_2S$, m. 83°.

W. O. E.

Synthetic drug studies. V. Preparation of benzyl compounds. H. P. KAUFMANN AND O. RITTER. Univ. Jena. *Arch. Pharm.* 267, 212-29(1929).—The study has been confined to the prepn. of certain benzylated hypnotics, anesthetics and laxatives, the following being more particularly characterized—1-phenyl-2,3-dimethyl-4-dibenzylamino-5-pyrazolone, $C_{22}H_{22}ON_4$, plates m. 102°; 5-benzyl- α -bromoisovaleryl urea, $C_{13}H_{17}O_2N_3Br$, leaflets m. 134°; *p*-phenacetylphenetidine, $C_{16}H_{17}O_2N$, long needles m. 128.5-30°; phenethenyl-*p*-diethoxydiphenylamidine, $C_{24}H_{23}N_2O_2$, leaflets m. 113°; *o*-benzylphenolphthalein, $C_{24}H_{26}O_4$, m. 175°; *O,O'*-diacetyl-*o*-benzylphenolphthalein, $C_{28}H_{30}O_6$, m. 134°; *O,O'*-phthalidene-bis(*p*-benzylphenol), $C_{24}H_{26}O_4$, leaflets m. 123°; *p*-rhodan-*N*-benzylamine, $C_{10}H_{11}N_2S$, needles m. 78°; *p*-rhodan-(*N*-methylbenzyl)aniline, $C_{13}H_{14}N_2S$, needles m. 63°; *p*-rhodan-(*N*-ethylbenzyl)aniline, $C_{16}H_{16}N_2S$, needles m. 54°; bis-(1-benzylamino-phenyl-4-)disulfide, $C_{20}H_{21}N_2S_2$, bright yellow needles m. 92°; bis-(1-methylbenzylamino-phenyl-4-)disulfide, $C_{22}H_{23}N_2S_2$, brassy needles m. 86-7°; bis-(1-ethylbenzylaminophenyl-4-)disulfide, $C_{24}H_{25}N_2S_2$, bright yellow needles m. 76°.

New German Pharmacopeia. I. HERZOG. *Arch. Pharm.* 267, 233-46(1929).—An address (commentary) on certain features of the new Arzneibuch.

W. O. E.

Odor and constitution among the mustard oils. VI. Natural mustard oils. G. MALCOLM DYSON. *Perfumery Essential Oil Record* 20, 42-4(1929).—A treatment of the production of the various mustard seed from the earliest times, descriptive more particularly of the method of sepg. the glucoside sinigrin from the seed and of the conversion to allyl thiocarbimide and glucose. The specifications for pharmaceutical mustard oil, as found in the various pharmacopeias, are tabulated. The 2 main methods employed in making synthetic mustard oil are indicated. White mustard oil, so-called sinabin oil, is likewise discussed in connection with other natural oils.

W. O. E.

Pine-needle extract. BOHRISCH. *Pharm. Ztg* 74, 291-9(1929).—From a large no. of analytical exams. it appears that this commodity is very frequently subject to adulteration, notably with sulfite liquor. In the examn. of pine-needle exts. recourse can be advantageously had to capillary analysis.

W. O. E.

Liquid soaps and their preparation in the apothecary. A. THIEME. *Pharm. Ztg* 74, 299-301(1929).—Methods are described for the pharmaceutical production of liquid soaps.

W. O. E.

Detection of heavy metals in magnesium salts. CREGOR KOGAN. *Pharm. Zentralhalle* 69, 449-50(1929).—The tests for heavy metals as prescribed in certain pharmacopeias (Russian and German) may lead to wrong conclusions in the presence of Fe, in which event the test should be carried out in HCl soln. Na_2S can be used as a reagent for heavy metals only in the absence of Fe.

W. O. E.

Constituents of red sandalwood. Homopterocarpin and pterocarpin. H. DIETERLE AND H. LEONHARDT. Univ. Berlin and Univ. Frankfurt a. M. *Arch. Pharm.* 267, 81-116(1929).—The results so far accomplished in the present investigation are given in the following summary: Homopterocarpin (A) has the formula $C_{17}H_{16}O_4$, m. 83-4°, and $[\alpha]_D^{20} -216^\circ 20'$. The Zeisel detn. shows the presence of 2 CH_2O groups which are *m*-substituents in a C_6H_4 nucleus. In spite of the fact that (A) possesses no

OH groups, it is nevertheless susceptible to acetylation, the resulting compd. being isomeric but not identical with *d*-acetyldihydro (*A*). (*A*) contains 2 O atoms in lactide-like combination with a 2nd aromatic nucleus. The hydroxy acid, representing this lactone, is known only in the form of its rather unstable ester. Attempts to acetylate the OH group resulted in hydrolysis of the ester, and reformation of the lactone. (*A*) contains no easily satd. double bond, since catalytic reduction effects no addn. of H, but rather the formation of 2 isomeric alkali-sol. dihydrohomopteroquinones, of which the *l*-dihydro (*A*) yields a dibromo deriv. The dibromohomopteroquinones contain a phenolic OH and have aldehyde character. Their formation is due presumably to a rupture of the lactone ring. Of the levo compd. Ac, Bz and CH₃O derivs. were prepd., while the optically inactive compd. yielded only the Bz deriv. *l*-Dihydro (*A*) is also formed on dehalogenation of dibromo (*A*) with nascent H in alk. media. Under like treatment (*A*) remains unchanged. Bromination, therefore, favors reduction. Against oxidative influences (*A*) is relatively stable. With HNO₃, however, it is changed 1st into dinitro (*A*) and a compd. of the formula C₁₈H₁₃O₈N₂, finally yielding trinitroresorcinol and oxalic acid. Distn. with Zn dust results in the formation of resorcinol dimethyl ether and methylanthracene. The latter cannot, however, be regarded as the fundamental hydrocarbon of (*A*), since in that case (*A*) would have to be considered a hydrogenated, not a methylated, deriv. of anthracene an assumption out of all harmony with its other characters. With all reserve, but chiefly as a foundation for further investigation, (*A*) is regarded as a deriv. of diphenylmethane with the following constitution:

Pterocarpin possesses the formula, C₁₈H₁₂O₄, m. 162.5–163°, and $[\alpha]_D^{20} = 220.1^\circ$. It contains a CH₃O and yields with Br a monosubstitution product. Its formula may be expanded to C₁₈H₁₂O₄(OCH₃). Among the compds. prepd. and characterized were *acetyldihydro* (*A*), C₁₈H₁₂O₆, needles m. 130–1°; *acetyldimethyl* (*A*), C₁₈H₁₄O₆, leaflets m. 220° (decompn.); *l*-*dihydro* (*A*), C₁₇H₁₀O₄, needles m. 153–4°; optically inactive *dihydro* (*A*), C₁₇H₁₀O₄, m. 76° (decompn.); *d*-*acetyldihydro* (*A*), C₁₈H₁₂O₆, needles m. 130.5–131°; *d*-*benzoyldihydro* (*A*), C₂₄H₁₈O₆, needles m. 99–100°; optically inactive *benzoyldihydro* (*A*), C₂₄H₁₈O₆, leaflets m. 67–70° (decompn.); *dihydro* (*A*) *methyl ether*, C₁₈H₁₂O₄, needles m. 57–8°; *acetyl* (*A*), C₁₉H₁₄O₄, leaflets m. 195°; *dibromo* (*A*), C₁₇H₁₀O₄Br₂, needles m. 184–5°; *dibromodihydro* (*A*), C₁₇H₁₀O₄Br₂, needles m. 199–200° (decompn.); *nitration products of* (*A*), (a) C₁₇H₁₀O₄N₂, needles m. 136–8°, (b) C₁₈H₁₂O₄N₂, needles m. 122° (decompn.); (c) C₁₈H₁₂O₄N₂, needles m. 244° (decompn.); *dihydropteroquinone*, C₁₈H₁₂O₄, m. 141–2°. Amorphous Se and (*A*) yield on heating under pressure the compd., C₂₄H₁₄O₄, leaflets m. 110° (decompn.), *acetyl deriv.*, C₁₉H₁₄O₆, scales m. 132°.

Detection and differentiation of acetone, methanol and isopropyl alcohol simultaneously present in galenicals. WALTER MEYER. *Pharm. Ztg* 74, 230–1 (1929). The procedure suggested is as follows: Distil 50 g. of the tincture carefully and under perfect condensation. This quantity will correspond in most cases to an alc. content of about 30 g. Reserve the 1st 5 cc. of the distillate for the usual tests for MeOH and AcMe. Receive the next 20 cc. in an Erlenmeyer flask surrounded by a cooling mixt. Acidify the residue in the distg. flask with H₂SO₄ to fix any C₄H₉N possibly present, and continue the distn. Mix the 2nd fraction of 20 cc. uniformly and divide into 2 equal parts. Treat one portion with K₂Cr₂O₇ and H₂SO₄, then distil the product. Now test equal portions of the unoxidized and of the redistd. oxidized fractions in accordance with the usual methods (directions of D.A.-B.6., technical provisions, Ellram, Denigès) for AcMe. Should the unoxidized portion be colorless or only faintly colored, and the oxidized portion on the other hand more or less strongly colored, then the pos. test for AcMe obtained with the 1st fraction is indicative of the simultaneous presence of isopropyl alc. in the sample under examn. If, however, both portions of the 2nd fraction remain colorless or equally strongly colored, isopropyl alc. is absent. Treat the remainder of the oxidized portion, as also 2–3 cc. of the 1st fraction, with KMnO₄ and test for MeOH.

W. O. E.

Conservation of anesthetic chloroform. I. G. OBERHARD. *Pharm. Ztg* 74, 260–1 (1929).—After a discussion of the probable types of decompn. of both dry, wet and pharmacopeial CHCl₃, it is shown that the substances best calcd. to conserve this anesthetic are acids, notably anhyd. citric, oxalic, or tartaric acids, the first named being pre-

ferred. The soly. of these acids in CHCl_3 has been detd., *i. e.*, citric (monohydrate) 0.028, (anhyd.) 0.012; oxalic (hydrate) 0.04, (anhyd.) 0.036; tartaric 0.014. The amt. of citric acid (powd.) to be added to CHCl_3 is 0.1%.

Unknown phenolic ether in oils of fennel and star anise. E. TAKENS. *Riechstoffind.* 4, 8-9 (1929). A fraction b_p 147°, d_{15} 0.967, α_D $\pm 0^\circ$, solidifying 21.5°, was isolated; it had a somewhat faintly insipid odor reminiscent of the higher ethers of eugenol. On distg. at atm. pressure the liquid foamed up at about 260°, at which temp. a phenol distd. over. Crystn. from C_6H_6 yielded crystals, m. 93-4°; it possesses a typical autumnal odor, and has the compn. of *p* propenylphenol, $\text{CH}_2\text{CH}=\text{CHC}_6\text{H}_4\text{OH}$.

W. O. E.

Essential oil of *Ambrosia mexicana*. B. N. RUTOVSKII AND I. V. VINOGRADOVA. *Riechstoffind.* 4, 10-1 (1929). The plants grown in the Crimea were subjected to various methods of distn. Fresh material yielded on steam distn. a viscous oil, while similar treatment of dry material gave a solid product. A sample of the liquid oil had the following characters: yield 0.022-0.039%, d_{20}^{20} 0.9532-0.9765, α_D 9.65-13.65°, n_D^{20} 1.4928-1.5116, acid no. 1.04-2.29, ester no. 78.61-105.95, ester no. after acetylation 123.96-154.13. The chief constituents appear to be a sesquiterpene alc. and a solid compd., m. 126-7.5°. A more comprehensive study is contemplated.

W. O. E.

Antiseptic action of essential oils. WALTER OBST. *Reichstoffind.* 4, 12-3 (1929).—A brief review.

W. O. E.

Russian essential oils. B. N. RUTOVSKII, *et al.* *Perfumery Essential Oil Record* 19, 391-3 (1928); cf. *C. A.* 22, 2436-7, 4716, 23, 239, 1717, 1721.—More new oils of possible value in perfumery have been obtained and investigated, and the resources of further districts examd.; each investigation comprises generally the examn. of oils from different plant parts at different periods. Thus, the twigs and needles of *Pinus halepensis* Mill grown in the Crimea gave 0.26% of an oil insol. in 90% alc., with the following consts: d_{20}^{20} 0.8960, α_D -49.44°, n_D^{20} 1.4940, ester no. 18.8 (after acetylation 54.83, total aces. 15.7%). Among the constituents identified were: α -pinene, camphene, primary and secondary aces. The yield of oil from *Cachrys alpina* grown in the Crimea varied from 0.16% from dry twigs to 1.09% from the umbels —from dry leaves 0.94%. A later distn. gave a much higher yield, 0.98% from fresh material (or 2.7% calcd. to the dry plant). This oil was insol. in 90% alc. gave no reaction for aldehydes and had d_{20}^{20} 0.8456, α_D 4.04°, n_D^{20} 1.4868, ester no. 3.9 (after acetylation 15.23); under atm. pressure 74% distd. from 178° to 183°, 20% from 183° to 195°, indicating a large proportion of terpenes. Among the identified products were: α -pinene, limonene and terpinene, an alc. and sesquiterpene. Of Caucasian *Thuja* oils, that from *T. occidentalis* was obtained in a yield of 0.46% and had d_{20}^{20} 0.9203, α_D -7.58°, n_D^{20} 1.4605, ester no. 25.46, (after acetylation 39.43); it was sol. in 0.2 vol. 90% alc. The identified constituents were α -pinene, α -thujone, fenchone, esters of AcOH and valeric acid. Fresh leaves of *T. varreana* gave 0.89% of oil in 1925, having d_{20}^{20} 0.9078, α_D -1.23°, n_D^{20} 1.4550, ester no. 16.36 (after acetylation 30.36); it was sol. in 0.1 vol. 90% alc. In it occurred sabinene, α -thujone and thujyl alc. In the same year the twigs of *T. gigantea* gave the enormous yield of 3.07% of oil having d_{20}^{20} 0.9145, α_D -1.21°, n_D^{20} 1.4552, ester no. 26 (after acetylation 47.15); it was sol. in 0.1 vol. 90% alc. It contained α -pinene, α -thujone and thujyl alc. During the course of the work the quant. soly. of thujone in aq. resorciol soln. was detd. and tested. The oil of *Siler trilobum* Scop. distd. in August, 1926, had d_{20}^{20} 0.8886, α_D +131.65°, n_D^{20} 1.4862, ester no. 41.58 (after acetylation 59.3); it contained aldehydes 40%, *d*-limonene 55%; α -pinene was indicated, *d*-perilla aldehyde was probable. The fresh oil had a blue color and probably contained azulene. In the course of the investigation into the odorous properties of aromatic and hydroaromatic analogs, several derivs. of perilla aldehyde were prepd., as *perillacrylic acid*, the

Me-Et and *isoamyl esters* of which were strongly scented. Besides the usual method in the presence of mineral acid, esterification to the Et ester was effected by the action of Et-OAc on perilla aldehyde in the presence of Na. By condensation of AcMe and AcH in the presence of 10% NaOH perilla aldehyde yielded perillydene acetone, diperillydene acetone and perillydene acrolein. With Bz glycine it gave a cryst. 2-phenyl-4-perillydene oxazolone-5, m. 137.8; a yield of 65-70% was obtained by warming equimol. proportions of the 2 substances with anhyd. NaOAc in Ac_2O . A Soudchum oil from *Laurus nobilis* L. was obtained in a yield of 0.915% and had the characters d_{20}^{20} 0.9167, α_D -19.6° , n_D^{20} 1.4690, ester no. 47.6 (after acetylation 67.3), cineole 50%, phenols 6%; it was sol. 1:2 in 80% alc. Other ingredients were: α -pinene, *l*- α -terpineol and a sesquiterpene. A Caucasian *Lavandula spica* gave a 0.7% yield of oil showing d_{20}^{20} 0.911, $\alpha_D + 2.02^\circ$, n_D^{20} 1.4675, ester no. 3.78 (after acetylation 108.23), camphor 25.5%, cineole 36%, α -pinene, *l*-linalol, borneol. Rotation-dispersion of essential oils was studied, the values for α_C , α_D , α_E and α_F at given temps. (all $20-1^\circ$) having been tabulated for 35 essential oils and 11 isolates, together with the dispersion ratio α_F/α_C . For most oils this value lies between 1.85 and 2.20. Noteworthy exceptions are *Piper nigrum* 2.81, *Juniperus virginiana* 2.80, *Eucalyptus globulus* 2.44, *Ocimum basilicum* and *Mentha pulegium* 2.75, *Andropogon nardus* 0.67. Of isolates, whose dispersion is generally higher, *d* camphor has 2.75, *l*-menthone 2.07, *d*-isomenthone 2.72, dihydrocarbone 3.30, methylcyclohexanone 2.50. It is recognized that this value may furnish another weapon against adulteration. The characters of 2 peppermint oils from the Saratov district were d_4^{15} 0.9156, 0.9210, $\alpha_D -17.93$, 14.39° ; n_D^{20} 1.4604, 1.4696; free menthol, 44.7, 41.2%; total menthol, 41.3, 48.1%; menthone, 5.3, 11.8%. From the tables given, the effect of age alone is evidently slight, there being simply a tendency for the rotation and ester value to rise a little. Essential oils of wild plants of Voronege district gathered in Aug. and Sept., 1926, yielded the following data in the order named: yield, d^{15} , α_D , n , ester no. (after acetylation), *Thymus odoratissimus*, 0.06%, 0.8682, 15.22° , 1.4755, 23.0 (50.2); *Achillea millefolium*, 0.15%, 0.904, -24.04° , 1.4742, 23.9 (81.0); *Mentha arvensis*, 0.12%, 0.9626, 28.2° , 1.4865, 47.4 (91.5); *Acorus calamus*, 1.05%, 0.9600, 12.00° , 1.5033; *Hyssopus creticus*, 1.05%, -0.9122 , -24.29° , 1.4743, 44.1 (88.0). A new method is suggested for the evaluation of coriander fruit. In each sample the foreign matter and the damaged fruit are detd., and the pure sample is passed through a series of sieves, giving the % of fruit of known diams. (a universal sieve of adjustable mesh was constructed for the purpose). The wt. of fruit in each group, the no. in 1 g., and the vol. (by submersion in water) were also detd. From these data the surface area of each group, and thence the total superficies are obtainable; the yields are considered a function of the total surface area. Examples are given showing that evaluations on this basis are commensurate with practical yields. The same principle has been applied to anise fruit, where, however, the size of the fruit also influences the oil yield.

W. O. J.

The scientific and economic importance of research on Indian medicinal plants. SUDHAMOY GHOSH. School of Tropical Med. and Hyg. Calcutta. *Indian Med. J.* 63, 650-3(1928).—The importance of standardization is stressed. Certain new drugs not accorded recognition by the B. P. or U. S. P. are given consideration. Statistics covering India's potential resources in this field are furnished. The importance of industrial enterprise to the production of various chem. commodities is emphasized. The manuf. of caffeine from tea-dust and of strychnine from *nux-vomica* seeds are examples of substances whose manuf. in India has proved economical. F. G. C.

The formation of essential oils and resin in conifers. XI. Characteristics of the oil and the resin in *Pinus silvestris* leaves in connection with the process of their formation. G. V. PIGULEVSKII AND N. B. RISKINA. Leningrad Univ. *J. Russ. Phys.-Chem. Soc.* 60, 1069-77(1928); cf. *C. A.* 22, 1433-4.—At the beginning of the growth of the acerose leaf, resin is formed first, then the production of oil also takes place, but the formation of resin always precedes that of oil. This militates in P.'s supposition that terpenes and sesquiterpenes are derived from complex resin acids. The secretion accumulates entirely during the first year of the growth of the acerose leaf; although some increase in the resin content is observed in the following years, it is merely due to the transformation of the essential oil into non volatile products. The oil of the leaves (without branches) is principally composed of pinene -14.88 , a complex ester, a free alc. and the sesquiterpene cadinene (rotation -5.52 ; $\alpha/\alpha_s = 8.96$). The ester content in the pine fluctuates widely (0.21 to 1.0%), the rotation of the polarization light fluctuates between $+10.84^\circ$ and -15.91° . The resin content of the pine fluctuates between 7 and 12%. The oil content in the acer-

tion of the 1-year leaves fluctuates between 3 and 8%. The oil content in 1-year branches changes within the limits 0.46-1.78%, rotation α_D -8.16° to -47.17° . **XII. The formation of the essential oil in *Pinus silvestris*.** G. V. PIGULEVSKII AND Z. M. ZAIKINA. Leningrad Univ. *Ibid* 1417-25; cf. C. A. 20, 1426.—The growth of the acerose leaf reaches its max. of development in mid-August. After Aug. 18, the increase of dry matter slows down. The max. accumulation of *essential oil* in the young leaves falls at the period from June 5 to 15; thus the intensive accumulation of the oil ceases before the intensive growth of the leaves is terminated. The oil content of the branches (without leaves) does not fluctuate much in the period of growth. The accumulation of oil in the branches commences earlier than in young leaves. The oil of the leaves is chiefly *l*-rotatory, though *d*-rotation from -15.44° to 7.52° is also encountered. The oil of the branches (without leaves) is *l*-rotatory from -15.3° to -45.68° . The resin accumulates in the acerose leaves in the early period of their development when the weight of 100 needles equals 0.29 g.; their max. resin content is July 15th. The resin accumulation precedes the essential-oil accumulation. The resin content increases somewhat in the 2nd year of the life of the leaves; as, however, the oil content does not increase, it may be supposed that the oil partly turns into non-volatile products. A considerable quantity of free acids and a little of complex esters enter in the compn. of the resin. A decrease of free acids is observed in the resin of 1-year leaves. B. N.

Essential oil of *Sesseli dychotomum*. V. I. NILOV. Timiriazev Acad. Rural Econ. *J. Russ. Phys.-Chem. Soc.* 60, 1575-7(1928).—*Sesseli dychotomum* of the family Umbelliferae, a plant which is grown in large quantity in Crimea, gave by steaming of its leaves an essential oil with a yield of 0.5% on the quantity of fresh material. The characteristics of 3 samples of the oil were: sp. gr. 0.8651 to 0.8754, rotation α_D -1.25 to -5.5 , n_D 1.4743 to 1.4783, acid no. 1.73 to 5.34, ester no. 11.24 to 15.74, ester no. after acetylation 20.3 to 40.22. To det. its compn. a 205-g. sample was distd. at 20 mm., whereupon 192 g. passed below 75° leaving a residue of 12.5 g. The distd. portion was fractionated at ordinary pressure and was found to consist of α - and β -pinene. The residue of 12.5 g. probably was composed of sesquiterpenes and of a small quantity of complex esters. BERNARD NELSON

Essential oil of the seed of *Smyrniun perfoliatum*. V. I. NILOV. Timiriazev Acad. Rural Econ. *J. Russ. Phys.-Chem. Soc.* 60, 1579-84(1928).—The essential oil obtained with a yield of 0.7% by steaming the seeds of *Smyrniun perfoliatum*, a Crimean wild plant, family Umbelliferae, is a wonderfully beautiful dark lilac-colored substance possessing an odor resembling patchouly. After distn., part of the oil crystd.; thus, 39 g. of the oil gave, on being cooled to -20° , 17.7 g. crystals and 21.3 g. liquid. The liquid consisted of a terpene, a sesquiterpene $C_{15}H_{24}$, and oxygenated compds. The crystals, which crystd. from EtOH in needles m. 56° , b; 143 - 144° , presented an oxygenated sesquiterpene of the compn. $C_{15}H_{22}O$; the properties of the latter indicate that it is a new compd. BERNARD NELSON

Mugho pine oil and its therapeutic uses. A. QUILICO. *Rivista ital. essenze profumi* 11, 7-8(1929).—The Cadore oil has a balsamic odor, is limpid, green-yellow, insol. in water, concd. alc., chloroform and ether, has $d_{20} 0.875$, rotates polarized light to the left 7 - 9° . It is a mixt. of *l*-pinene, phellandrene, silvestrene, cadinene and bornyl acetate. German mugho pine oil contains 5% bornyl acetate, and Italian 9-10%. R. SANSONE

The inapplicability of a test of the official Pharmacopeia on alcohol. G. MACCONE. *Boll. chim. farm.* 68, 55-6(1929).—The Italian Pharm. prescribes the following test for examg. 95% EtOH for the presence of AcH: 10 cc. of EtOH dild. with 10 cc. H_2O must not turn brown when heated with a few drops of a reagent consisting of 3 parts of $AgNO_3$, 30 parts of 4.5% NH_3 and 3 parts of NaOH in 30 parts of H_2O . M. points out that every com. EtOH will give a pos. reaction with this technic since the reagent alone on heating will turn brown spontaneously, which is due to the fact that addn. of NaOH makes the reagent unstable. G. SCHWOCH

The narcotics and the esters (and ethers) of morphine in regard to the rules laid down by the Geneva convention. D. MIGLIACCI. *Boll. chim. farm.* 68, 57-8(1929). G. SCHWOCH

Medicinal musts. I. CERUTI. *Giorn. farm. chim.* 78, 59-60, 63-4, 67-8(1929).—Directions are given for the prepn. of grape juices used in the making of elixirs, sirups, etc., for medicinal purposes. G. SCHWOCH

The standardization of insulin. S. E. DE JONGH. *Arch. nêerland. physiol.* 11, 454-9(1926).—J. notes that an extraordinary inconsistency appears in the published work on the standardization of insulin. His preliminary work was as follows: 15 rabbits were taken and divided into groups of 3; doses of insulin were injected subcutaneously, in the proportions 1, 2, 3, 4 and 5, to each group and the blood sugar was detd.

at the end of 2 hrs. The tests were continued for 5 successive weeks when each animal had had a dose of each of the 5 strengths of insulin. The expts. were continued on different batches of animals until the dose was found that reduced the blood sugar to 0.049% or less in 75% of the animals. The final tests were then carried out on 12 animals; the unknown sample was compared directly with the international standard. On the first day the animals were given 0.55 unit of the standard and the other 6 animals a dose of the sample estd. to be the equiv. of 0.55 unit. After a week the expt. was repeated with the groups reversed. The hourly blood sugars after the injection, taken for 4 hrs., were averaged and the means calcd. The means for all the animals on the unknown should not differ by more than 10% from the same animals on the standard. Consistent results were not obtained if only 3 animals were used in each group. M. H. SOUTE

The purification of insulin. E. DINGEMANSE AND E. LAQUEUR. *Arch. néerland. physiol.* 12, 259-64 (1927); cf. C. A. 22, 823.—Material having a strength of 1.1 to 1.5 mg. per convulsive dose can be purified from 4-5 times by electrolysis. To an acid soln. of the material a potential of 110 v. is applied for several hrs. The insulin and part of the albumin migrate toward the cathode, where the insulin and part of the impurities flocculate. Insulin of 0.15 mg. per convulsive dose cannot be purified further by electrodialysis; it is therefore shaken for $1\frac{1}{2}$ hr. with 0.01 N NaHCO₃. The insulin remains undissolved and is centrifuged off, dissolved in acid and pptd. with EtOH and Et₂O. A purification of from 2 to 6 times is thus effected, but the method is of no use with pure material. The insulin is, therefore, adsorbed on charcoal with 20 to 25% of the accompanying impurities, the charcoal is centrifuged off and dried *in vacuo*. The insulin is recovered by means of liquid phenol from which soln. it is pptd. by 30 vols. of slightly alk. H₂O (NaHCO₃). The convulsive dose is now 0.045 to 0.07 mg., the unit 0.015 to 0.025 mg. Crystals have been obtained but they are the same as those obtained from sepd. inactive material. M. H. SOUTE

The international regulation for the standardization of insulin. S. E. DE JONGH AND E. LAQUEUR. *Arch. néerland. physiol.* 12, 277-84 (1927). Different criteria have been used to det. equivalence of dosage in the blood sugar methods of standardizing insulin: (1) disappearance of x mg. sugar per 100 cc. of blood (MacLeod, etc.), (2) the av. fall expressed as a percentage of the initial blood sugar value (Marks, etc.), (3) the min. value reached, the initial value being of no importance (the authors). The authors have analyzed 200 injections in which 0.55 unit of the same prepn. has been given to the rabbits. The initial blood-sugar values are divided into 10 groups from 0.186 to 0.075%, by steps of 0.011, and the min. also into 10 groups from 0.095 to 0.006, by steps of 0.008. Initial values above 0.14% are uncommon and there is a tendency for a high min.; between 0.14 and 0.086%, the av. min. lies between 0.055 and 0.04%. Therefore, within limits the final value is independent of the initial value, while the amt. of sugar that disappears is not independent of this value. The same conclusion is drawn when the initial value corresponding to the groups of min. are found, thus between 0.071 and 0.024% min. values, the initials only vary from 0.113 to 0.105%, on the av. Below 0.024%, the initials tend to lie below 0.096%. The dose of insulin necessary to give the same effect in animals of different wts. is not proportional to the wt. M. H. SOUTE

Bio-assay of preparations of ovarian follicular hormone. E. P. BUGBELL AND A. E. SIMOND. Parke, Davis and Co. *J. Am. Pharm. Assoc.* 17, 962-6 (1928). Prepn. contg. ovarian follicular hormone are assayed for biological activity by injecting the solns. into white rats from which the ovaries have been completely removed. If adequate doses are injected the rats will come into estrus and show the same evidence of heat that normal rats show when in that condition. B. and S. propose the adoption as the standard unit in the bio-assay of prepn. of the ovarian hormone, the rat unit, originated and defined by Allen, Doisy and associates in 1925 (C. A. 19, 319). B. and S. propose the adoption of a standard technic for the bio-assay of prepn. of the ovarian follicular hormone. The technic is as follows: (1) Select normal, healthy, female white rats between 3 and 11 months of age, keep them in well ventilated, clean, dry quarters in which the temp. is maintained const. between 70° and 76° F. (2) Feed the rats an adequate amt. of a well-balanced diet contg. sufficient vitamins. (3) Examine vaginal smears daily for a period of 2 weeks to det. if the estrus cycles are regular. (4) Perform complete ovariectomy on those rats which have regular estrus cycles at intervals of 4-6 days. (5) If any doubt exists as to the completeness of the ovariectomy, take vaginal smears daily to make sure that there are no spontaneous estrus cycles. (6) Prevent atrophy of the uteri by the injection of sufficient follicular ovarian hormone every week or every 2 weeks to cause estrus growth of the uteri. (7) After ovariectomy allow 1 week for recovery from the operation before making use of the rats for testing

prepn. (8) In testing oil solns. of the ovarian follicular hormone give 3 subcutaneous injections at 4-hr. intervals in one day. (9) In testing aq. colloid solns. and true aq. solns. give 8 subcutaneous injections, 4 on each of 2 successive days. (10) Take vaginal smears at intervals of approx. 48, 52, 56, 72, 76 and 80 hrs. after the first injection. (11) The reaction caused by ovarian follicular hormone is the production of *typical estrus* in which stage 2 vaginal smears contain only squamous cells. (12) This reaction should occur in 48–51 hrs. after the first injection and should last several hrs. (13) Use at least 12 rats in testing a prepn., 3 to be given the same dosage. (14) The minimal effective dosage is that in which 2 out of 3 rats given the same dosage show *typical estrus*. (15) Consider the standard rat to be one weighing 140 g. (16) When rats weighing more than this standard are employed reduce the results to the 140 g. standard.

L. E. WARREN

Microchemical reactions for quinine. M. WAGENAAR. *Pharm. Weekblad* 66, 177–82(1929).—The reactions discussed are sublimation, pptn. as free base, pptn. as sulfate, selenate, ferricyanide, thiocyanate, nitroprusside, chromate, complex sulfate-periodide, selenate-periodide, chloraurate, mercuric chloride, and as salts of various org. acids including meconic and mellitic acids. Several of these reactions are sufficiently delicate to detect 2 mg. quinine at a diln. of 1:1000.

A. W. DOX

Determination of quinine as herapathite. GUSTAVE A. STICHT. *Chemist-Analyst* 18, No. 2, 10–11(1929).—To salt contg. about 0.477 g. of total alkaloid, add 25 cc. 95% EtOH and 1 cc. of 3.3 N H₂SO₄. Stir and heat to boiling on the water bath. When the solid has dissolved completely add 10 cc. of hot I₂ soln. and allow to stand for 2 hrs. Then filter, drain by suction and wash with alc. which is satd. with herapathite made by the same procedure as was used for the pptn. Dry at 100° and weigh. The wt. multiplied by 0.72 gives quinine expressed in terms of the anhyd. sulfate. To prep. the I₂ soln. dissolve 33 g. of KI in 700 cc. of 95% alc. and add 33 g. of powd. tartaric acid. Shake for some time to ppt. KHC₄H₄O₆, add 50 g. of I₂. Filter, wash with alc. and dil. to 1 l.

W. T. H.

Controlling fire and explosion hazards of anesthetics (WARDELL) 24. Odoriferous products from musk, etc. (RUZICKA) 10. Technical importance of adipic acid and its derivatives (SCHRAUTH) 10. Ether (Ger. pat. 408,020) 10. Anthraquinone derivatives [intermediates for making pharmaceutical products] (Brit. pat. 295,943) 10. Bz-1-Hydroxybenzanthrone and similar compounds (U. S. pat. 1,705,868) 10. Laboratory mill suitable for comminuting drugs (U. S. pat. 1,706,643) 1.

Therapeutic complex compounds of metals. I. G. FARBENIND. A.-G. Brit. 295,734, March 17, 1927. Sol. complex metallic compds. are formed by interaction of an oxide, hydroxide, or carbonate of a metal, with an alkali metal, NH₄ or amine salt of a pyrocatecholsulfonic acid, a pyrocatecholcarboxylic acid or a pyrogallolsulfonic acid. The amine salts may be those of ethylamine, benzylamine, or the like. Examples are given of the prepn. of the Cu, As, Cd, Mn, Sn, Cr and V compds. of the pyrocatechol-disulfonic acid obtained by sulfonating pyrocatechol with oleum; of the Cu, Al, ferrous and ferric compds. of the pyrocatecholmonosulfonic acid obtained by treating pyrocatechol with H₂SO₄; of the Cu, ferrous, ferric and Sn compds. of pyrotocatechuic acid; of the Sb, Bi, Sn, Cd, V, Mn and Pb compds. of the pyrogalloldisulfonic acid obtained by sulfonating pyrogallol with oleum; and of the Sb compd. of the pyrogallolmonosulfonic acid obtained by treating pyrogallol with H₂SO₄. Au and Ag compds. are also mentioned. Vanadyl hydroxide for use in prepg. the V compds. may be made by reducing NH₄ vanadate with hypophosphorous acid in HCl soln, followed by pptn. with Na₂CO₃.

Salts of alkaloidal bases, etc. I. G. FARBENIND. A.-G. Brit. 295,656, Aug. 16, 1927. The bases are combined with a methylene compd. of an aromatic carboxylic or sulfonic acid or a deriv., or double decompn. is effected in a solvent, such as water, between a salt of the base and a salt of the acid. *Therapeutic products* are obtained which are neutral or acid salts, tasteless, stable in air, sol. in water and readily decomposed by acids and alkalis into their components. Examples are given of reactions between 1-(N-methyldiethylaminoethyl)amino-4-aminobenzene and methylenebis(salicylic acid) and between methylenebis-β-hydroxynaphthoic acid and N-ethyldiethylaminoethylaniline, 1,2-dimethoxy-4-[N-bis(diethylaminoethyl)amino]benzene, 6-methoxy-N-diethylaminoethyl-8-aminoquinoline, 6-methoxy-N-(α-diethylamino-β-methylbutyl)-8-aminoquinoline, β-diethylamino-β'-(6-methoxy-8-quinolyl)aminoglycol di-Et ether, 6-methoxy-8-aminoquinoline, quinine and other cinchona alkaloids, and strychnine.

Derivatives of *m*-alkylaminobenzoic acid and sulfonates of the methane series. CHEMISCHE FABRIK VORM. SANDOZ. Swiss 127,962 to 127,966, Mar. 9, 1927. Addns. to Swiss 126,679 (C. A. 23, 612). Equimol. quantities of *m*-alkylaminobenzoate and CH_4 or C_2H_6 sulfonates are allowed to react. The products are used in *therapeutics*.

A saccharated compound of aluminum acetate. KALLE & Co. A.-G. (Edmund Birschel, inventor). Ger. 469,235, Sept. 4, 1924. A soln. of Al acetate is mixed with sol. carbohydrates and quickly evapd. to dryness, giving a stable compd. Thus, beet-sugar is dissolved in a soln. of Al acetate and evapd. *in vacuo* at about 60°. Other examples mention cane-sugar, lactose and dextrose as being treated in a similar way.

Ointments. I. G. FARBENIND. A.-G. Fr. 646,836, July 13, 1927. Ointments and the like are made by incorporating the usual constituents in aq. solns. of sulfenic acid, which possess wetting properties, or their salts, such as the Na salt of butyl- or isopropyl-naphthalenesulfonic acid.

Making preparations from isolated endocrine glands. K. N. KRAVKOVA. Russ. 5,293, Sept. 15, 1924. Ringer-Locke soln. is introduced into the vascular system of the isolated gland. The extract so obtained is filtered through a Chamberlain filter to obtain a sterile prepn.

Preparing an extract from the pituitary gland. O. A. STEPPUN. Russ. 4,957, Mar. 31, 1929. The pituitary gland freed from the capsule is finely macerated in a dil. HCl, neutralized with caustic, coagulated by boiling, subjected to the action of colloidal Fe_2O_3 , and added to a filtered chloretone soln.; the method is characterized by the maceration being carried out gradually with varying quantities of HCl and the finished ext. being slightly acidified to litmus with HCl.

Vitamins by irradiation. A. J. PACINI (to C. M. Richter). Brit. 296,053, Aug. 24, 1927. Substances contg. growth-producing vitamins (such as substances which may be obtained from typhoid bacilli, brown rot of peaches, sarcomatous tissue, *agaricus campestris* and ergot of rye, by soln. in alc. and acetone and by removal of fats to leave a residue insol. in water) are treated with various rays other than the ultra-violet rays to produce antirachitic substances. X-rays, rays from a Lenard tube, canal rays and cathode rays may be used although heating with infra-red rays is particularly suitable. Vitamins insol. in water are treated to obtain an active sol. product by digesting with aq. Na taurocholate and glycocholate at 100°. The soln. is filtered and evapd. to dryness, the residue dissolved in alc., neutral Pb acetate added to ppt. Pb glycocholate and basic Pb acetate added to ppt. the taurocholate. Excess Pb is pptd. with H_2S , and the alc. soln. when evapd. to dryness leaves an active residue sol. in water.

Vitamin D. I. G. FARBENIND. A.-G. Brit. 296,093, Aug. 26, 1927. In irradiating ergosterol with ultra-violet rays, the exposure is interrupted before all the ergosterol has been transformed, the interruption being preferably made at a point when the absorption of rays of wave lengths between $\lambda = 300$ and $\lambda = 230$ is approx. at a max.

Hormones. I. G. FARBENIND. A.-G. Brit. 295,680, Aug. 17, 1927. The hormones of the anterior lobe of the hypophysis and of the ovaries are obtained from the urine of pregnant women, or from other human or animal fluids or exts. of organs, by pptg. the former hormone with a large excess of alc., acetone, or the like and by extg. the ovarian hormone from the alc. or like filtrate, or from the starting material before the pptn. by ether, CHCl_3 , or other org. solvent immiscible with water. Numerous details of procedure are given. Cf. C. A. 22, 4204.

Hormones. SCHERING-KAHLBAUM A.-G. Brit. 295,361, Aug. 10, 1927. The process described in Brit. 291,005 (C. A. 23, 1218) for activating hormones from sexual organs by irradiation with ultra-violet rays is applied also to the treatment of hormones from vegetable organisms such as those described in Brit. 271,492 (C. A. 22, 1654). The irradiation may be applied to the vegetable materials before extraction or to the crude or purified extd. material.

Dyes. R. W. FRENCH and W. C. HOLMES. Brit. 295,605, Feb. 8, 1927. Addn. products which may be used as *bactericidal and therapeutic agents* or as *biological stains* are made by treating salts of basic dyes such as Bismarck brown R, Thioflavine T, Auramine O, Brilliant green, rosaniline, Methyl violet, acriflavine, Benzyl violet, Rhodamine B, Safranin T, New blue DA, Thionine and Pinachrome with phenolic compds. such as phenol, cresol, resorcinol, pyrocatechol, hydroquinone, guaiacol, phloroglucinol, or pyrogallol. The products may be obtained by the direct fusion of the ingredients or by mixing aq. or other solns.

Bacterial products for diagnosis and therapeutic uses. I. G. FARBENIND. A. G. Brit. 295,629, Aug. 15, 1927. Substances stated to show a "tuberculin action" are obtained by treating prepn. of bacteria of the coli group by the process previously applied to tubercle bacilli as described in Brit. 285,087 (C. A. 22, 4726).

Isolating filter-passing viruses. ERNST FRIEDBERGER. Ger. 471,105, June 8, 1927. The "capillary elevation method" for the sepn. of bacteria (see C. A. 14, 1839) is now applied to the sepn. of an invisible or filter-passing virus, e. g., the virus of small pox from accompanying bacteria. The virus ascends a wick of filter paper to a greater height than the bacteria.

18—ACIDS, ALKALIES, SALTS AND SUNDRIES

E. M. SYMMES

A new caustic soda and soda-ash process. WILHELM SIEGEL. *Chem.-Ztg.* 53, 145-7(1929).—The basis of the new process is: $\text{CaF}_2 + \text{SiF}_4 + 2\text{NaCl} (+ \text{acid}) = \text{Na}_2\text{SiF}_6 + \text{CaCl}_2$; Na_2SiF_6 (at 700°) $= 2\text{NaF} + \text{SiF}_4$; $2\text{NaF} + \text{Ca(OH)}_2 = 2\text{NaOH} + \text{CaF}_2$. No difficulties are found with the last reaction; the real problem is in converting the pptd. CaF_2 into NaF simply and cheaply. Various patents for this are considered. It is improbable that this process will compete with NaCl electrolysis or the Solvay process.

E. M. SYMMES

Potash from New Jersey greensands. Preliminary report. J. R. THOENEN. Bur. Mines, *Repts. of Investigations* No. 2910, 54 pp.(1929).—Although the area in which greensands have com. possibilities is cut to 3.7% of Washington's est. and 17.6% of Mansfield's calcn., and the K_2O content to 5.3% of Washington's and to 23% of Mansfield's est. there still remains a potential reserve capable of supplying this country's needs for nearly 500 years. At present no large-scale, successful process is in operation. Expansion of existing exptl. processes would encounter difficulties in marketing by-products. Foreign potash fertilizers can be distributed at seaboard and in interior points at lower freight rates than similar products from New Jersey.

E. M. SYMMES

The production of good lime in the gas-fired kiln. FRANZ MÜLLER. *Tonind.-Ztg.* 53, 291-3(1929).

KAUSCH, OSCAR: Der Schwefelkohlenstoff. Seine Eigenschaften, Herstellung und Verwendung. Berlin: Julius Springer. 265 pp. M. 32. Reviewed in *Ind. Eng. Chem.* 21, 392(1929).

Nitric acid. W. R. ORMANDY. Brit. 296,121, May 25, 1927. HNO_3 and N oxides are formed by combustion of oil or other fuel in a flame submerged in water in the presence of a catalyst such as a compd. of V, Ni, Cr, Fe or other metal which forms a plurality of oxides. The catalyst may be mixed with the fuel or with the air used for combustion. Lime or CaCO_3 may be added to the water to neutralize the acid formed and prevent corrosion of the app. The flame may serve also for generating steam.

Phosphoric acid and phosphates. I. E. WEBER, H. E. ALCOCK and B. LAPORTE, LTD. Brit. 295,848, Sept. 22, 1927. H_3PO_4 alone or in admixt. with acid phosphate is made by reaction of a mineral phosphate such as superphosphate with H_2SO_4 and heating to $150-200^\circ$ to destroy org. matter.

Removing dissolved silicic acid from aqueous liquids. A. ROSENHEIM. Brit. 295,317, Aug. 9, 1927. In processes similar to those described in Brit. 291,435 (C. A. 23, 1221) dissolved silicic acid may be removed from the liquid treated by the use of gels of titanatic acid, stannic acid, Th oxide, Zr oxide, tungstic or molybdic acid, or the oxides or hydroxides of Cu, Zn, Cd, Fe, Ti, Al, Mn or Mg. These substances may be mixed with or pptd. on other materials such as coke, activated C, charcoal, chalk, marble, pumice, calcined clay, textile fabrics, sawdust or cellulose. Water treated may be filtered through alternate layers of active and inactive substances. The active substances may be regenerated by treatment with sol. substances forming complex silicates such as tungstates or molybdates, or with alkali salts, hot water, steam or substances dissolving silicic acid or adsorbed bases.

Carbon dioxide. F. W. GEERE. Brit. 295,842, Sept. 9, 1927. Acid substances for admixture with carbonates or bicarbonates for controlled production of CO_2 , as described in Brit. 276,146 (C. A. 22, 2444), are prepd. by mixing a liquid acid such as H_3PO_4 or H_2SO_4 with an acid salt or with a neutral salt in proportion more than sufficient to form the acid salt and coating the particles of the mixt. with a material such as a fat, wax or hydrogenated oil. A further quantity of acid salt is added and the mixt. is ground.

Sulfur trioxide. A. O. JAEGER (to Selden Co.). Brit. 296,048, Aug. 24, 1927. Catalysts for SO_3 production comprise multi-component zeolites formed by the interaction of one or more silicates, one or more metallates and one or more metal salts, the basic radicals of which enter the non-exchangeable part of the zeolite. Catalytically active elements or radicals are combined in or used with the zeolite. The silicate component may be an alkali metal silicate or a silicate sol in alkali and may be partly replaced by alk. salts of acids of the elements S, N, Sn, As or Sb. The metallate component may be a sol. alkali metal compd. of Al, Cr, Zn, V, Be, Sn, Pd, Pt, Ti, Pb, W, B, Mo, U, Ta, Cu, Ni, Fe, Co, Ag, Cd, Mn, Zr, Th or Ce, or a complex compd. of these metals formed with NH_3 , HCN, sulfoxyonic acid, oxalic acid, formic acid, tartaric acid, citric acid, glycerol or sugars. The metal salt may be a water sol. salt of the elements Cu, Ag, Au, Be, Zn, Cd, Al, rare earths, Ti, Zr, Sn, Pb, Th, Cr, U, V, Mn, Fe, Ni and Co. Alkali metal cations in the zeolite may be replaced by the cations NH_4 , Cu, Ag, Au, U, Mg, Ca, Zn, Sn, Th, V, Cr, Sr, Cd, Ba, Al, Ti, U, Mn, Fe, Co, Pd, Ni, Pt or complex ions contg. them. Numerous details and modifications of the products are described. Cf. C. A. 23, 1221.

Oxidizing ammonia to nitric oxide. CLARK W. DAVIS (to E. I. du Pont de Nemours & Co.). U. S. 1,706,055, March 19. NH_3 and O contg. gas are passed through a catalyst comprising a Pt alloy contg. Rh 2-50%.

Formation of ammonia during the preparation of oxalates and formates. AMERICAN CYANAMIDE Co. Ger. 468,807, Dec. 11, 1924. A mixt. of cyanamides and cyanides of the alkali and alkaline earth metals is converted into NH_3 and formates or oxalates by water at high temps. or high pressures. Ca compds. are particularly suitable for the process.

Continuous concentration of ammonia solution. E. T. SHEVCHENKO. Russ. 5312, May 31, 1925. NH_3 soln. enters the lower chamber of an evapng. column divided into several vacuum chambers. A rotating shaft going through all chambers provided with a suitable equipment by which the NH_3 soln. is thoroughly mixed and a vacuum created, increasing with each chamber. The liquid passes gradually through the chambers, the gases being gradually withdrawn.

Porous solid material for storing ammonia or other gases or liquids. FREDERICK G. KEYES (to National Refrigerating Co.). U. S. 1,705,482, March 19. A porous material comprises an oxychloride cement of a metal of the second group such as Zn oxychloride and Na silicate together with CaCl_2 or a similar chloride. U. S. 1,705,483 specifies the use together of activated charcoal, Mg oxychloride and CaCl_2 for similar purposes. U. S. 1,705,484 specifies the use of a halide such as CaCl_2 capable of forming addn. products with fluids such as NH_3 together with oxychloride cement and alundum cement.

Purification of alkaline lyes. I. G. FARBENIND. A. G. Fr. 646,912, Jan. 10, 1928. Alk. lyes contaminated with org. substances are treated in an autoclave above 100° with O or gases contg. O, and if necessary any alkali carbonate formed is converted into the hydroxide by the addn. of oxides or hydroxides of alk. earth metals. Examples are given in one of which the lye contains α - and β -cellulose.

Precipitates of heavy metal salts. ALEXANDER WACKER GESELLSCHAFT FÜR ELEKTROCHEMISCHE IND. G. M. B. H. Fr. 646,507, Dec. 20, 1927. Ppts. of heavy metal salts to be used for the protection of plants and vegetables are obtained in a form which will dry to a powder. Thus, a concd. soln. of Pb acetate is pptd. by a soln. of Na_2CO_3 forming a ppt. of basic carbonate which dries to a powder and which may be mixed with water.

Alkali iodates. I. G. FARBENIND. A. G. (Heinrich Heimann and Hans B. Seeböhm, inventors). Ger. 468,213, Oct. 20, 1927. Addn. to Ger. 451,656. In the catalytic prepn. of alkali iodates from the iodides, metal oxides are used besides alkali hydroxides. Thus, a mixt. of KOH and KI was heated to 525° and Bi_2O_3 added to form KIO_3 . Al_2O_3 may be used as the catalyst. Cf. C. A. 22, 3744.

Aluminum compounds. T. R. HAGLUND. Brit. 295,227, May 2, 1927. Al sulfidiferous material is first treated to convert the Al sulfide into oxide under such conditions that sulfide impurities are substantially unchanged and these impurities are

then removed by treating the material with Cl or Cl compds. or their mixts., or with salts such as chlorides, sulfates and nitrates of metals which are pptd. by H_2S in acid soln. so that sulfides of metals such as Fe, Ti or Ca are converted into volatile or sol. salts. Before treatment with Cl, corundum crystals are sepd. from the decompn. product and $Al(OH)_3$ is heated to convert it into oxide. The treatment with Cl or with HCl, sulfochlorides or $AlCl_3$ preferably is effected at a sufficiently high temp. that chlorides of Fe and Ti are volatilized. Numerous details and modifications are described. Cf. C. A. 23, 673.

Ammonium sulfate. ESCHWEILER BERGWERKS-VEREIN. Fr. 646,814, Jan. 7, 1928. Highly concd. $(NH_4)_2SO_4$ is produced by neutralizing the H_2SO_4 with the gases contg. NH_3 in the same container as that in which the crystn. takes place.

Potassium dichromate. A. V. VINOGRADOV. Russ. 5356, May 31, 1928. $K_2Cr_2O_7$ is obtained from chromium iron ores by burning with sunflower ash with or without the addition of lime.

Potassium manganate. SOC. CHIMIQUE DES USINES DU RHÔNE. Brit. 296,074, Aug. 26, 1927. In a process such as that described in Brit. 292,991 (C. A. 23, 1480), KOH lyes contg. 50% KOH, instead of 60–80%, may be used for the prepn. of K manganate without using an excessive rate of flow of air or O, if the temp. is raised above 200° (preferably to 210 – 220°).

Red lead. E. HAYWARD. Brit. 295,975, Feb. 22, 1927. Reaction of Pb or a Pb compd. such as the carbonate or PbO under heat and pressure with air or O is effected continuously without loss of pressure in the reaction chamber and pressures of 20–30 atm. and temps. of 450–700° may be employed. A jacketed reaction chamber which may be heated by molten Pb and which is provided with special outlet and inlet valves and a screw conveyor is described.

Soda. SOC. FRANÇAISE DE SUCRATERIES (Brevets et procédés Deguide). Fr. 646,228, May 10, 1927. NH_3 is recovered in the manuf. of Na_2CO_3 or $NaHCO_3$ by treating the NH_4Cl formed with BaO instead of CaO. The $BaCl_2$ is treated with H_2SO_4 for the recovery of HCl, and BaO may be reformed from the sulfate.

Pulverizing saltpeter. I. R. KERICHEVSKII. Russ. 5494, May 31, 1928. Saltpeter is dissolved in hot water and emulsified with a liquid in which it is not sol. The saltpeter is then sepd. in the form of a fine powder after the soln. is cooled.

Purifying zinc salt solutions. ALBERT VOHL and WILHELM WACHTENDORF. U. S. 1,706,196, March 19. Zn salt solns. contg. impurities such as solns. resulting from vulcanized fiber manuf. are subjected to oxidation and compds. of the Fe group and pptg. agents other than Zn compds. are removed (suitably by addn. of $ZnCO_3$); the resulting soln. is evapd. and heated with an oxidizing agent such as $Zn(ClO_3)_2$ or $Ba(ClO_3)_2$ and Zn powder and HCl are added to reduce any remaining traces of Fe, the heating is continued, and the soln. is then suitable for reuse in mfg. processes. Cf. C. A. 22, 143.

Carbon disulfide. ALADAR VON VAIDAFFY. Ger. 469,839, Feb. 17, 1926. CS_2 is prepd. by treating S, or inorg. sulides which liberate S when heated, with org. compds. contg. exclusively or principally C and H at temps. between 380° and 450° . A contact agent may be used. C_2H_2 is mentioned as a suitable org. compd. The S source may be gas purification waste.

Carbon disulfide. ZAHN & CO., BAU CHEM. FAB. G. M. B. H. Ger. 469,170, Oct. 5, 1927. Addn. to Ger. 467,929 (C. A. 23, 1728). In the distn. and rectification of CS_2 , the impure liquid is first warmed in a container and then led into a S separator prior to the distn.

Apparatus for carbon disulfide manufacture and similar reactions. THOMAS GRISWOLD, JR. (to Dow Chemical Co.). U. S. 1,705,614, March 19. Vertical retorts are charged with solid material (such as charcoal for CS_2 manuf.) from magazines extending above the retorts, and reacting material (molten S in the case of CS_2 manuf.) is supplied to vaporizing compartments at the base of the retorts. For CS_2 manuf., the retorts are preferably made of ceramic material and the vaporizing compartments of cast iron. The vaporizer is made integral with a superposed ash-collecting compartment from which it is sepd. by a horizontal partition.

Hydrogen and nitrogen. HYDRAZOTE. Fr. 645,970, Dec. 20, 1927. In the production of H and N by the action of steam on reduced Fe, in which the reaction is endothermic, and of air in which the reaction is exothermic, the reactions are carried out in the same app. to economize heat. Details of construction are given.

Separating hydrogen and carbon dioxide. JOSEPH KEILLY and ETHELBERT W. BLAIR (to Commercial Solvents Corp.). U. S. 1,706,707, March 26. A mixt. contg. H and CO_2 such as fermentation gas is compressed and washed with a solvent liquid such

as water under pressure to remove a greater part of the CO_2 and the residual gas is then further washed under pressure to remove substantially all the CO_2 , the pressure is released on the solvent liquid to recover the dissolved H-bearing gas and the latter is returned to the raw gas under compression. An arrangement of app. is described.

Zinc. STANLEY COCHRAN SMITH. Fr. 646,664, Dec. 31, 1927. See Brit. 287,186 (C. A. 23, 487).

Active carbon. EDMUND KÜCHLER (Franz Krczil, inventor). Ger. 466,358, May 23, 1926. Addn. to Ger. 453,972. Highly active H_2SiO_3 contg. C is prepd. by coating granulated C with siliceous gel.

Active carbon. GES. FÜR CHEM. PRODUCTION M. B. H. and HELLMUTH MÜLLER-CLEMM. Ger. 468,212, July 6, 1923. Addn. to Ger. 461,884. Highly active bleaching C is prepd. from the waste liquor of cellulose sulfite lye by adding alkali sulfide, or polysulfide soln. until no further pptn. of CaCO_3 occurs, filtering off the ppt., evapg. the filtrate and carbonizing the residue. Thus, K_2S is added to waste liquor to ppt. the Ca content which is then filtered off. Or, CaO is dissolved in the min. amt. of water and waste liquor added under pressure and the whole heated. The ppt. is sepd. by pressing and dehydrated to the fullest extent. It is then treated with K_2S and boiled to dissolve org. substances. CO_2 is bubbled in to ppt. the C and the filtrate is evapd. and carbonized.

Active carbon. METALLBANK UND METALLURGISCHE GESELLSCHAFT A.-G. Fr. 646,481, Dec. 28, 1927. Active C is made by treating wood, cellulose, starch, sugar, lignite, etc., or C at high temps. with Na_2O . Other substances such as NaCl or Na_2CO_3 may be added. The process may be used for increasing the activity of or revivifying active C.

Active carbon. I. G. FARBENIND. A.-G. (Fritz Winkler, inventor). Ger. 469,277, July 11, 1925. Addn. to Ger. 463,772 (C. A. 22, 4212). Active C is prepd. from charcoal or carboniferous materials by the action of hot gases thereon in a shaft furnace. Air is blown into the furnace in the vicinity of the surface of the C layer.

Activated charcoal. I. G. FARBENIND. A.-G. Fr. 646,897, Jan. 9, 1928. See Brit. 283,485 (C. A. 22, 4212).

Vertical lime kiln and associated pyrometer construction. ARTHUR E. TRUESDELL. U. S. 1,706,423, March 26. Structural details.

Rollers and reciprocating grating for discharging shaft lime kilns. KLÖCKNERWERKE A.-G. ABT. MANNSTADTWERKE. Ger. 471,410, Aug. 20, 1925.

Catalyst. COMPAGNIE NATIONALE DE MATIÈRES COLORANTES ET MANUF. DE PRODUITS CHIM. DU NORD RÉUNIES ÉTABLISSEMENTS KUHLMANN. Fr. 646,263, May 13, 1927. A catalyst particularly for the partial oxidation of hydrocarbons of the aromatic series has a basis of oxides of V lower than V_2O_5 . Thus pumice may be impregnated with a soln. of vanadyl oxalate obtained by dissolving vanadic acid in oxalic acid in excess, and heated to 270° .

Catalysts for oxidation of organic compounds. A. O. JÄGER (to Selden Co.). Brit. 295,270, Aug. 8, 1927. Catalysts contg. a nonsiliceous base exchange material are formed by the reaction of one or more metallates with one or more metal salts, either by pptn. from aq. solns. or by fusion (in which case metal oxide and Na or K hydrates or carbonates may be used instead of metallates). The metallate component may consist of alkali metal salts of Al, Cr, Zn, V, Be, Sn, Pd, Pt, Ti, Zr, W, U, Ta, B or Mo or of complex compds. contg. NH_3 or cyanogen complexes. The metal salts may be sol. acid or neutral salts of Cu, Ag, Au, Be, Zn, Cd, Al, rare earths, Ti, Zr, Sn, Pb, Th, Cr, U, V, Mn, Fe, Ni, Co, Pt or Pd. Numerous details, modifications, examples and uses of the products are given.

Contact mass. RHENANIA-KUNIGIM VEREIN CHEM. FABRIK A.-G. and BERNHARD C. STUER (Bernhard C. Stuer, inventor). Ger. 467,220, Sept. 5, 1922. Contact masses for the prepn. of condensation and oxidation products of C_2H_2 are obtained by the partial reduction and dehydration of higher metallic oxides. Thus, H is passed over red hot $\text{Fe}_2\text{O}_3 \cdot n\text{H}_2\text{O}$ to form water-free FeO . A mixt. of C_2H_2 and NH_3 is then passed over the oxide at 400° to form acetonitrile, picoline and analogous bases. Instead of pptd. Fe(OH) , the mineral brown iron ore can be used. Another example gives V_2O_5 as the metallic oxide to be reduced to form the contact mass.

Plastic composition. G. F. JANLEY and O. PARDOEN. Brit. 295,372, Aug. 11, 1927. A compn. which is stated to be incombustible, acid-resistant and relatively non-conductive, for making molded articles or rolled sheets may be formed of asbestos powder 5, a "lamellate material" 2, "stearine vegetable gum" or oxides of Pb 1 and linseed oil 1 part. Hardening may be retarded by the addn. of alc. or ether.

Plastic compositions. PAUL HALLER and HANS KAPPELER. Swiss 127,950,

July 16, 1926. Addns. to Swiss 123,515. PhNH_2 or one of its salts is allowed to react with CH_2O in an acid medium till a jelly is formed. The mass is then treated with org. bases and dried. Thus, 1 mol. of PhNH_2 is suspended in water and 1 mol. of 25% HCl and $1\frac{1}{4}$ mol. of 40% CH_2O are added. The product is cooled to $40-60^\circ$, forming a plastic mass which can be molded to desired form. Methylamine is then added and the mass dried. In Swiss 127,951 the acid medium is replaced by a strong electrolyte and the org. base by an agent which is not basic but weakly acid such as NaF , ammonium oxalate, $(\text{AcO})_2\text{Zn}$, $(\text{AcO})_2\text{Pb}$, Na_2S , H_3BO_3 , CH_2O , HCO_2H , glycerol and pyrogallol.

Plastic material. MATHIEU VAN ROGGEN and JEAN É. D. DE GRANVILLE DE BIELIZE. Fr. 646,918, Jan. 10, 1928. Plastic materials are obtained by condensing phenol with a large excess of CH_2O , using MgO , Na_2CO_3 , or a mixt. of Na_2CO_3 and Na_2BO_3 as catalyst. A little paraffin may be added to make the material more elastic.

Plastic substances. PFENNING-SCHUMACHER-WERKE G. M. B. H. Fr. 646,877, Jan. 9, 1928. See Ger. 466,053 (C. A. 23, 1729).

Adhesives. CONSORTIUM FÜR ELEKTROCHEM. IND. G. M. B. H. (Wolfram Haehnel and Willy O. Herrmann, inventors). Ger. 471,278, May 12, 1926. See Can. 277,169 (C. A. 22, 2644).

Adhesives containing cellulose esters. I. G. FARBENIND. A.-G. Brit. 295,366, Aug. 10, 1927. Adhesives are formed of a cellulose ester such as nitrocellulose or waste film material, together with solvents, plastifiers, softeners or the like and finely divided solid substances such as bronze powders, sawdust, kaolin, talc, flour, gypsum or asbestos. Several examples with proportions of ingredients are given.

Casein. OTTO GERNGROSS. Ger. 470,287, Dec. 7, 1926. Casein which has been hardened by CH_2O is dissolved in NH_4OH of higher concn. than 5%. Heat or pressure may be used. Thus, powd. artificial horn is dissolved in 10% NH_4OH at 70° .

Molded receptacles of wood pulp and casein. JOHN OLSON. U. S. 1,705,780, March 19. A plastic mixt. formed of wood pulp, casein and water is pressed between dies under very high pressure so that the casein is caused to permeate the wood pulp and form a unitary rigid article, and the dies and molded article are relatively moved at high speed to finish the article.

Condensation products. FRANZ HASSLER. Ger. 466,269, Mar. 18, 1926. Aromatic hydrocarbons or their derivs., especially those contg. the OH , NH_2 and NH groups, condensed according to the process described in Ger. 405,994, are further heated. Thus, naphthalene, S and concd. H_2SO_4 are heated to 150° for 20 hours. The product is reheated to 150° and a further quantity of naphthalene stirred in. The condensation products obtained by the method of the prior patent may have added, phenol, benzidine, fuchsin, aniline and naphthylamine.

Condensation products from *p*-halogenated phenolic compounds and aldehydes. MAX WEILER, BERTHOLD WENK and HERMANN STÖTTER (to I. G. Farbenind. A.-G.). U. S. 1,707,181, March 26. Reaction is effected between an aldehyde such as CH_2O or a sulfo benzaldehyde and a phenolic compd. such as *p*-chlorophenol or *p*-bromophenol which contains at least 1 OH group with a halogen atom in *p* position to the OH and at least one free *o*-position to the OH group and which may be substituted in the other positions by "indifferent" substituents; a condensing agent such as H_2SO_4 may be used. The products are suitable for moth-proofing textile fabrics.

Artificial substances. SOC. ANON. POUR L'IND. CHIM. À BAËLE. Fr. 646,921, Jan. 10, 1928. Artificial substances prepd. by causing aromatic amines to react with CH_2O in an acid medium or otherwise till a solid jelly is formed have their density increased by pressure preferably when heated. Thus, PhNH_2 is condensed with CH_2O in the presence of HCl soln., the product is steeped in 3% NaOH soln., washed and submitted to a pressure of 110 atm. at 150° for 1 hr. The sp. gr. is increased from 0.6 to about 1.0. Fr. 646,922 relates to the removal of acid by one or more washings with NaOH soln. when aromatic amines are condensed with aldehydes in acid medium. A final pressure treatment as in Fr. 646,921 may be given.

Deodorizing and preserving substance. SOC. ANON. POUR L'IND. CHIM. À BAËLE. Swiss 127,967, Aug. 10, 1928. Addn. to Swiss 124,635. The substance consists of a solid mixt. of condensation products of urea or its derivs. sol. in water, and CH_2O , together with a substance possessing the deodorizing or preserving property, such as NaNO_2 .

Waterproofing vegetable protein-base glue. GEORGE H. OSGOOD. U. S. 1,706,674, March 26. A high-protein content vegetable meal such as peanut, cotton seed or linseed meal is used with $\text{Ca}(\text{OH})_2$, Na_2CO_3 , Na silicate and water and is admixed with a

witherite. Thorough mixing is necessary. The BaCO_3 should be present in slight excess. The reaction must be given time to go to completion. R. F. F.

Smooth-surface tile. V. S. SCHORY. *J. Am. Ceram. Soc.* 12, 75-8(1929).—A body which has proven satisfactory in service is: flint 7, Conn. feldspar 31, Tenn. feldspar 31, English china clay 23 and Ky. ball clay 8%. The kiln atm. is very important. It must not be too sharply reducing. C. H. KERR

A study of the absorption of two earthenware bodies and their resistance to crazing in the steam test. E. P. WRIGHT. *J. Am. Ceram. Soc.* 12, 118-22(1929).—An ivory and a white earthenware body, fired in different positions of periodic and tunnel kilns, and maturing to various absorptions were subjected to autoclave tests at 100 and 150 lbs. per sq. in. The ivory body resisted the crazing induced by this test for absorptions from 7 to 8% in the 100 lb. test. The white body withstood the test up to absorption of 8.5%. Thorough glaze firing had some effect in increasing the resistance. In the 150-lb. test, the critical resisting absorption was lowered to 6% for each body. C. H. KERR

The vapor absorption of a fired earthenware body. C. L. DEEDS. *J. Am. Ceram. Soc.* 11, 769-70(1928).—Trials fired at 3 temps. were placed over 10% H_2SO_4 for 30 days and the gain in wt. was detd. Up to a certain point, absorption was proportional to porosity, but the body with the highest absorption, 20.25%, took up a relatively higher amt. of H_2O . With an absorption of 8.81%, the max. H_2O vapor taken up was 0.13%. With 10.8% absorption the H_2O vapor taken up was 0.16%, and with 20.25% absorption it was 0.54%. C. H. KERR

The mathematical fundamentals of burning stoneware. W. SCHUBN. *Land. Ztg.* 53, 168(1929).—The method for calcg. kiln efficiency is given. A comparison is made of the various fuels. High-volatile coal is considered best. Gas coal and lignite briquet are suitable. Coke is not recommended. R. F. F.

The thermal expansion of pottery bodies. TOSAKU YOSHIOKA. *J. Japan Ceram. Assoc.* 35, 459-63, 506-10(1927).—The relations between heat treatment in clay working and strength of the products, thermal endurance of pottery and thermal expansion of bodies and glazes are discussed. S. KONO

Method of measuring thermal expansion of pottery body. TOSAKU YOSHIOKA. *J. Japan Ceram. Assoc.* 35, 508-72(1927).—Dilatometers are classified and special features of each are given. A dilatometer devised by Y. consists, in the main, of a silica tube, a mechanism to rotate a mirror, a lamp and a scale. S. KONO

Theoretical considerations on the thermal expansion of pottery bodies. TOSAKU YOSHIOKA. *J. Japan Ceram. Assoc.* 36, 11-19(1928).—The literature pertaining to the thermal expansion of pottery bodies, clays, quartz, tridymite, cristobalite, silica glass and feldspars, the transformation of cryst. and amorphous silica, vol. change occurring in the transformation of the modifications, and the influence of porosity and grain size on the thermal expansion of the bodies are reviewed and discussed. S. KONO

The fibrous structure of porcelain bodies. RYOICHI SHIGEMUNE. *J. Japan Ceram. Assoc.* 35, 615-21(1927); cf. *C. A.* 22, 853. —In porcelain bodies with fine feldspar grains passing through a No. 200 sieve, the original shapes of feldspar grains were rarely shown and the development of the fibrous structure was poor. Three bodies (A) composed of 30% orthoclase of the Hakuho Island of 50-80 mesh size, and of 70% Korean kaolin, (B) composed of kaolin-quartz mixt. corresponding to Al_2O_3 25.50%, and (C) pure alumina, were fired at 1350-1370° (Cone 12+) for 67, 23½, or 8½ hrs. The photomicrographs of the specimens show that the fibrous crystals were universally developed in the feldspar grains in the specimens which were fired long and had suitable groundmass. The fibrous structure was developed best in body B fired for 67 hrs., whereas no crystals were observable in body A fired for 23½, and 8½ hrs. in any specimens of body C. The observations of Morrey and Bowen (*C. A.* 16, 2824) led S. to an opinion that the fibrous crystals in porcelain bodies are probably leucite. Its formation is most influenced by the time of firing and the nature of groundmass. The fact, noted by Morrey and Bowen, that long heating is necessary for the formation of leucite is probably due to the viscosity of feldspar, which is lowered by long heating. The effect of the nature of the groundmass is not chem. but is entirely phys. The favorable influence of the highly siliceous groundmass in the body B is due to its low viscosity, which allows the effective development of the fluidity of the orthoclase grains and thereby aids in the formation of the fibrous structure. S. KONO

Pyrophyllite, a new ceramic raw material. O. R. SHELTON. *N. Car. State Coll. J. Am. Ceram. Soc.* 12, 79-82(1929); cf. *C. A.* 23, 1023. —N. Car. deposits are described. A typical analysis is: SiO_2 64.54, Al_2O_3 28.88, Fe_2O_3 0.45, MgO trace, CaO

0.36, Na_2O 0.12, K_2O 0.18, H_2O 5.40%. It promises to be of value in whiteware, and is being tested in refractory and glaze work. C. H. KERR

Scratch hardness tests of ceramic materials. LOUIS NAVIAS. *J. Am. Ceram. Soc.* 12, 69-74(1929).—Three sets of standard (1) a mineral set per Mohs' Scale, (2) a set of steel samples, (3) a set of Carboloy samples were prepd. and used on ceramic products with satisfactory results. C. H. KERR

New method of direct firing glazed ceramic bodies. F. A. WHITAKER. *J. Am. Ceram. Soc.* 12, 87-95(1929).—A description is given of an adaptation of Carboradiant principle to a rectangular kiln for sanitary ware. C. H. KERR

Some leadless borosilicate glazes containing nickel oxide. H. H. HOLSCHER. *J. Am. Ceram. Soc.* 12, 111-7(1929).— NiO has not proved useful in glossy, non-opaque glazes. It is not recommended for use where a deep (dark) color is desired but it can be made to produce very pretty opaque glazes, light tan in color and of a semimat character. C. H. KERR

Copper ruby glaze. I. TOSAKU YOSHIOKA AND SHO HIRAOKA. *J. Japan Ceram. Assoc.* 35, 608-14(1927).—Coarse grains of frits, Na_2O (1-4) SiO_2 , contg. 2% of CuO were heated in a current of H_2 , CO , CO_2 , N_2 or O_2 at 600-1000° for 1 hr. N_2 and CO_2 were found most suitable for the production of red. The following frits

(A) 0.5 Na_2O { 2.0 SiO_2	(B) 0.375 Na_2O { 0.075 K_2O	} 0.125 Al_2O_3 { 2.5 SiO_2	(C) 0.25 Na_2O { 0.15 K_2O
0.5 CaO { 0.5 B_2O_3	0.55 CaO { 0.375 B_2O_3		
0.25 Al_2O_3 { 3.0 SiO_2	(D) 0.125 Na_2O { 0.225 K_2O	} 0.375 Al_2O_3 { 3.5 SiO_2	and (E) 0.3 K_2O { 0.7 CaO
0.25 B_2O_3 { 0.65 CaO	0.65 CaO { 0.125 B_2O_3		

0.5 Al_2O_3 .4 SiO_2 , each contg. 1% CuO with or without 1% As_2O_3 , BaO , Fe_2O_3 , PbO , SnO_2 or ZnO , were reheated for 1 hr in an atm. of N_2 or CO_2 at 600-1200°. Frits of types A and B are unfit for the production of red. In frits of type C which contain PbO , Fe_2O_3 , SnO_2 or ZnO beautiful ruby reds were produced when they had been heated at 800° or better at 700°, SnO_2 being most favorable in this respect. Some grayish reds were obtained with frits D and E. An atm. of CO_2 produces brighter glazes than an atm. of N_2 . S. KONDO

Titanium crystal glazes. SEIJI KONDO. *J. Japan Ceram. Assoc.* 35, 431-58 (1927).—The results of expts. on Ti crystal glazes applied on hard biscuit porcelain tiles are reported. The glazes had the compn. $n\text{R}^{\text{I}}_2\text{O}$ (1 - n) $\text{R}^{\text{II}}\text{O}$. $m\text{SiO}_2$. (2 - m)- TiO_2 , in which R^{I} = K, Na or K + Na and R^{II} = Zn, Ca, Zn + Ca, Mg or Mn. Also, in one series the sum of SiO_2 and TiO_2 , instead of being 2, varied from 0.8 to 2.7. The ranges of compn. in which good glazes were produced and the cone nos. at which they were fired are indicated. S. KONDO

The influence of glaze on insulator strength. D. H. ROWLAND. *Gen. Elec. Rev.* 32, 136-8(1929).—Test data are given showing the tremendous effect of surface conditions on mechanical strength of porcelain. It is possible to increase or decrease strength of porcelain by glazing. Glaze and porcelain must be balanced to avoid tension. M. McMAHON

Early strength cements. A HASCH. *Tonind.-Ztg.* 53, 146-8(1929). F. O. A.

Graphical calculation of all possible practicable mixtures of more than two raw materials for hydraulic cements. F. W. MEIER. *Tonind.-Ztg.* 53, 211-3(1929).—Starting with a fixed hydraulic modulus H ($CaO/(SiO_2 + R_2O_3)$) calc. the amounts of the raw materials in pairs (for a total of three raw materials) which will give H and calc. the silica modulus S (SiO_2/R_2O_3) for each pair. Plot the results in a S -percentage diagram and draw smooth curves for each of the three mixes. When S is fixed the relative amounts of the three are fixed. For 4 raw materials proceed in the same way working with 3 at a time. F. O. ANDEREGG

Calcium sulfate and its action on the mechanical properties of cement. PETER P. BUDNIKOV AND V. M. LESHORV. *Pit (Quarry)* 17, No. 11, 47-51(1929).—The effects are given of varying percentages of gypsum and anhydrite on the tensile and compressive strengths, setting times and soundness of previously ground cement. Max. strengths are secured with the addn. of 3 to 4% after which the strengths drop off, although with 20% anhydrite the strength begins to increase a little. The anhydrite was prepd. by heating gypsum to 700° for 4 hrs. F. O. ANDEREGG

History of the manufacture of blast-furnace cement at the Imperial Steel Works. MUNEO TANI. *J. Japan. Ceram. Assoc.* 35, 573-9(1927). A brief history of the cement manuf., a description of the plant, and the properties of the cement manufd. from 1913 to the present time are given. S. KONDO

Aluminous cement. HENRY LECHATELIER AND ANDRÉ DUHAMEAUX. *Chimie et industrie Special No.*, 417-23(April 1928). See C. A. 22, 4751. A. P.-C.

Tensile strength of the mixture of alumina cement and portland cement. Eizo MIKI. *J. Japan. Ceram. Assoc.* 35, 622-3(1927).—Setting time and tensile strength of varying mixts. of a port. cement and alumina cement were studied. The mixts. contg. 30-80% of port. cement set too quickly for ordinary purposes. Twenty % of the alumina cements can be replaced by the port. cement without material decrease in their early strength, while small addn. of the aluminous cements to port. cement is injurious. S. KONDO

The hardening of portland cement and the formation of free lime. SIGERU YAMANE. *Bull. Inst. Phys. Chem. Research (Japan)* 7, 1177-90(1928); *Abstracts* 1, 113-4; (in Esperanto).—Free CaO was detd. by the NH_4 acetate method of Emley and of Lerch and Bogue. Tests with cement- H_2O mixts. show that the greater the amt. of H_2O , the more CaO is formed. In cement- H_2O 100:20, CaO began to form only after 5 hrs. and almost reached the max. at 8 days, which indicates that at least up to 5 hrs. the hardening may be due to formation of $3CaO \cdot Al_2O_3 \cdot nH_2O$. Tensile strength does not increase parallel with the amt. of CaO formed, which shows that $CaO \cdot SiO_2 \cdot mH_2O$ can appear from the supersatd. soln. independently of CaO formation. Only about $1/4$ of the $3CaO \cdot SiO_2$ in clinker is decompd. in cement- H_2O mixts. but mixts.

contg. sand can have a better efficiency. Calcn. shows that if $\text{CaO} \cdot \text{SiO}_2 \cdot m\text{H}_2\text{O}$ is the chief strength-producing constituent, the final ratio of strengths for a cement- H_2O mixt. 100:22 and a cement-sand- H_2O mixt. 25:75:12 should be 1:0.85, which agrees well enough with actual values. Hence the sand, beside other functions, acts as a conservator of H_2O , which increases the efficiency of the $3\text{CaO} \cdot \text{SiO}_2$ in clinker. By powdering and heating hardened cement and putting 1 g. in a mixt. of 5 cc. glycerol with 30 cc. abs. alc., shaking, heating and filtering, V. obtained an opalescent suspension which, with the ultramicroscope, showed slowly moving pointlike particles. Addition of H_2O coagulates it at once. This possibly proves that *colloidal particles* exist in hardened portland cement.

AUSTIN M. PATTERSON

Fuel economy in the rotary kiln burning portland cement clinker. R. D. PIKE, Pike and West, Emeryville, Cal. *Ind. Eng. Chem.* 21, 307-10(1929); cf. *C. A.* 23, 1733.—P. continues the discussion of possible fuel economy and gives theoretical results to be obtained in the rotary kiln. Data given in previous articles are used (*C. A.* 23, 255, 1733). Several curves are given and P. shows from these what the effect of kiln size, surplus air, exit gas temp., and fuel economy in waste-heat generation should be. P. states that the efficient rotary kiln can save heat by lengthening the kiln to utilize the waste heat in the gases for preheating the charge, as well as using a regenerative cooler to heat the secondary air with heat from hot clinker, and placing a layer of insulating brick back of the fire brick in the upper parts of the kiln. 1,100,000 B. t. u. per barrel is probably the ultimate economy to be obtained. Good operation should give an efficiency of 50 to 60%. The theoretical heat required is 405,000 B. t. u. per barrel, and one may expect in special kilns to obtain results such that the fuel consumption will be 700,000 to 800,000 B. t. u.

M. C. ROGERS

Strength increase of cement and concrete. STIG GIERTZ-HEDSTROM AND DONAVAN WERNER. *Tek. Tid.* 58, Kemi 6, 41-5(1928).—Equations are set up connecting the size distribution of a cement with the strength developed and checked by applying to 3 cements. The compressive strength developed is proportional to the square of the cement hydrated, indicating the importance of fine grinding for early strength.

F. O. ANDERSON

The use of blast-furnace slag in concrete. WILHELM KOSFELD. *Stahl u. Eisen* 49, 243-9(1929).—The possible use of slag in concretes and the economies obtained thereby are discussed.

J. A. S.

Thermal conductivities of walls, concretes, and plasters. E. GRIFFITHS. *Sci. Ind. Research Building, Research Tech. Paper No. 6*, 1928, 19 pp. A presentation of the methods used for detg. the heat transmission of materials commonly used for building purposes.

B. C. A.

Distilling tar (Brit. pat. 205,087) 21.

ALEXANDER VACKER GEMEINSCHAFT FÜR ELECTROCHEMISCHE IND. G. m. b. H. Fr. 645,910, Dec. 19, 1927. A good cement is made from the residue left in the production of C_2H_2 from CaC_2 , if only a small amt. of water is allowed to act on the CaC_2 , so that the residue remains quite dry.

Cement. ANNE-LUTHER WERKE BRAUNSCHWEIG DER "MIAG" MUHLENBAU UND IND. A. G. Fr. 640,077, Dec. 22, 1927. See Brit. 284,294 (*C. A.* 22, 4756).

Cement. ANGELO FALCHETTO. Swiss 127,975, Jan. 17, 1928. A waterproof cement is made by mixing cement, water, alkali carbonate, org. acids and a hydrocarbon. The acid may be AcOH , and the hydrocarbon petroleum.

Cement. G. POLYSIUS EISENGIESSENRII UND MASCHINENFABRIK. Ger. 4 Jan. 1, 1920. In melting cement, a part of the furnace gases is used to preheat the air or gases for combustion and the rest to dry and calcine the initial materials. A rotating tube furnace for use in the process is described.

Apparatus for making cement by the wet process. THOMAS RIGBY. U. S. 1,706,747, March 26. An upright tube for drying slurry is connected adjacent its lower end to a gas exit of a cement kiln and at its other end to a centrifugal dust separator and collector; a slurry spraying device is positioned at the lower end of the drying tube and a rotating scraper for removing the slurry operates against the inner wall of the tube. Various other structural details are also described. U. S. 1,706,748 relates to a process of making cement by the wet method in an inclined rotary kiln having a sep. drying zone and calcining and clinkering zones. A plurality of independently controlled streams of finely divided atomized slurry flow along converging axes to the interior of the surface of the drying zone and hot gases of combustion are passed counter-current to the atomized slurry and the slurry is maintained in suspension in the current

of gases until sufficiently dried that it will not tend to stick together and form large lumps. U. S. 1,706,749 relates to app. for carrying out a similar process of slurry treatment, as does also U. S. 1,706,750.

Rotary kiln suitable for cement manufacture. ROLAND E. MINOGUE (to Minogue Engineering Co.). U. S. 1,707,191, March 26. Structural details are given of a device for feeding flue dust to the kiln of a wet process cement plant.

Revoluble cement kiln and material feeder construction. ROBERT W. RYDER (to Santa Cruz Portland Cement Co.). U. S. 1,706,592, March 26.

Concrete. M. L. GLOVER. Brit. 295,545, Jan. 17, 1928. In forming roads, foundations, roofs, etc., an upper layer comprises aggregate of various sizes and cement proportioned to form interstices which are partly filled with stone chippings, gravel or sand and partly with bitumen, tar or like material applied as an emulsion, and a lower layer is formed of dense concrete, some of the aggregate of which interlocks with the aggregate of the upper layer.

Concrete. C. S. JOHNSON. Brit. 295,894, Jan. 9, 1928. In order to proportion water and aggregate in desired quantities for making concrete, aggregate having a variable moisture content is combined with water until the sum of their wts. at a given combined volume equals a predetd. amount. An app. is described including a telescopically adjustable hopper in which the ingredients may be proportioned by displacement of water by the solid materials such as moist sand used in the aggregate.

Molding faced concrete units. WILLIAM R. TUCKER. U. S. 1,706,865, March 26. In molding units such as building blocks, facing stones are placed on the bottom of a mold and the spaces between them are filled with material such as rock screenings; the stones and screenings are submerged to a suitable level in glue or other suitable adhesive, drained and dried, unattached screenings are sep'd. and the mold is filled with facing and backing concrete mixts.

Paving. KARL SCHNEBLE. Swiss 128,176, Sept. 26, 1927. A plastic mass composed of finely divided pumice stone, siliceous earth, cement and water is rolled over the surface to be paved and allowed to set.

Coloring stone chippings for pavements. A. EDGE. Brit. 295,956, March 15, 1927. Stone chippings and stone dust are heated and then impregnated with a pigment mixt. formed by adding a half gal. of "white spirit" or turpentine substitute to each lb. of a paste composed of linseed oil 144, a green or red dry pigment 112 and an aniline dye of corresponding color 1 part. The colors may be permitted to penetrate for several days and the product is suitable for use on tennis courts.

Pavement or roadway construction. SAMUEL S. SADTLER (to Amiesite Asphalt Co. of America). U. S. 1,706,077, March 19. A compact foundation course is formed of water-repellent clayey earth mixed with a small quantity of Zn stearate, and is overlaid with a surface course of asphaltic material which can be laid without heating. U. S. 1,706,078 specifies adding to clayey earth from 5 to 10% of caustic lime and water sufficient to produce a mixt. having a consistency similar to that of freshly mixed cement, heating this mixt. to 75-100° while thoroughly agitating it, and then laying it as a road foundation course. Cf. C. A. 23, 2009.

Road covering. HANS ARBLI & Co. Swiss 127,733, Jan. 10, 1928. A durable and cheap covering layer for roads is composed of rough stones mixed in cold asphalt.

Bituminous emulsions. HERMANN PLAUSON (to Mineral A. G. Brig). U. S. 1,706,590, March 26. In prepg. compns. suitable for use on roads, a bituminous material such as "Spramex" is melted and emulsified with a previously formed emulsion of a neutral glyceride such as bone fat or fish oil in an excess of alkali carbonate soln.

Tar emulsions. EUSTAS DELVAUX and SADI DELVAUX. Fr. 646,271, May 14, 1927. A compn. contg. tar, an emulsifying agent, such as resin soap, and a starchy material, such as flour and water, is used to emulsify tarry substances, asphalts, etc., for use on roads.

Building material. WILHELM BUCHMOLZ. Ger. 471,150, Jan. 13, 1928, addn. to 431,741, and 471,151, Feb. 18, 1928, addn. to 471,150. Ger. 342,593, 409,944, and 431,741 describe compns. for making rammed walls, etc., comprising dolomitic lime mixed with lava grit and (or) other volcanic deposits, blast-furnace slag, or concrete grit, a small addn. of a concrete cement being made to accelerate the hardening. Such compns. are now modified by addn. of trass or CaO to the initial mixt., to improve the thermal cond. (471,150), and by using warm Ca(OH)₂ soln. to bind the mass and further accelerate the hardening (471,151).

21—FUELS, GAS, TAR AND COKE

A. C. FIELDNER

The second industrial heating exhibition, 26 June-8 July, 1928, at Paris. ANON. *Chaleur ind.* 9, No. 98(1928).—This number is devoted to a general account of the exhibition. It was divided into A. (1) manuf. of solid fuels including lignite, peat, wood, briquets, (2) manuf. of liquid fuels including synthetic products, (3) manuf. of gaseous fuels including different kinds of gases and gas producers. B. Utilization of fuels including furnaces, grates, burners, construction work, refractories. C. Draft, natural and artificial. D. Heat utilization including high-pressure boilers, recuperators, steam-plant accessories. E. Heat Conservation. F. Heat control. G. Steam utilization. H. Heat technic. S. L. B. ETHERTON

Manufacture of smokeless fuel. P. WEISS AND N. BEAUGRAND. *Chaleur ind.* 9, 200-7(1928).—La Compagnie des Mines de Vicoigne, Noeux et Drocourt (V. N. D.) now sells an anthracite substitute called "anthracine" which is made from fines with 12-13% volatile matter mixed with a varying amt. of fatty or flaming coal and pitch, in a rotary press. The plant consists of 8 sheet-iron cylinders set around a central distributor. The cylinders are 5½ m. high by 3½ m. diam., with 2 poke holes. Steam may be admitted at the top or bottom and there are pyrometers at top, bottom and in the middle of the charge. The charge can be cooled before emptying from the furnace. The rate of heating is adjusted to previous lab. detns. The steam is withdrawn at 150-200° and contains tar which is worked up. There are 4 diagrams of the plant and 1 of the layout. S. L. B. ETHERTON

Fuels and their combustion. ROGER MARTIN. *Chaleur ind.* 10, 85-95(1929). The article deals with the detn. of the higher calorific value and the elementary analysis of a fuel, when its nature is known. The following cases are considered with graphical solns.: (A) Knowing the proximate analysis (1) to det. the elementary analysis of the fuel and its calorific value, (2) to det. the upper calorific value, (3) to det. the lower calorific value when (a) no C remains in the ash and (b) when C remains in the ash, (B) knowing the proximate analysis and its upper calorific value to find its elementary compn. The latter calcul. is asserted to be accurate. S. L. B. ETHERTON

Synthesis of fuels in Germany. M. MATIGNON. *Chaleur ind.* 9, 328-33(1928). Lignites or tars are hydrogenated by a modification of the Bergius process. The lignites are dried, grained, homogenized with tar or heavy products from earlier runs and hydrogenated in an autoclave similar to that used in NH₃ synthesis. Hydrogenation lasts 25-30 mins. at about 425-450° and about 80% of the C present in the lignite is liquefied. The refinery capacity is 50,000 tons. The generator is 35 m. high and makes 120,000 cu. m. hr. of gas. The problem of dust removal from the gas has not yet been solved. A short description of lignite mining is added. From 5 to 6 tons of lignite produce 1 ton of carburant, of which some 100,000 tons appear to be made; it is suitable for Diesel engine work. S. L. B. ETHERTON

Manufacture of lump fuels agglomerated by heating. HENRI DUPUY. *Chaleur ind.* 9, 292-3(1928).—Lean coal dusts are mixed with fatty coal dusts and are pressed in the usual briquetting press. These briquets are weak mechanically but can be charged to the skips used for heating. The heating lasts 40 mins., finishing at 680°. The loss in weight is about 5% calcd. on dry C and its volatile content is about 6%. The cohesion is better than that of ordinary briquets; the density is about 1.2, the hardness may be increased by finishing at a higher temp., and the fuel is ram and sun-proof. The fuel is heated in buckets by steam from a metal superheater. The gas obtained may be utilized. A sketch of the installation is added. S. L. B. E.

The different systems of storing liquid fuels. BRUNO MÖLLER. *Appar.-tech.* 41, 31-3(1929). J. H. MOORE

Low-temperature distillation. J. ARNOUL DE GREY. *Chaleur ind.* 9, 243-52(1928).—G. favors external heating with its admitted lower thermal yield, metal retorts because of better conduction and tightness, thin layers of charges, heating on one side and removing the gas on the opposite side, thereby avoiding cracking and other deleterious effects. Lower Thuringen lignite contains S 0.5-1, ash 5-10, moisture 30-50% and in the lab. gives 100-120 l. oil per dry ton. Before treating, the lignite is dried to 15-20% moisture. The semi-coke is briquetted for domestic consumption. The primary oil may be used in Diesel engines. A description of the Rolle plant is given. G. then classifies different types of retorts thus: (1) directly heated, (2) with refractory walls, (3) with thick metal enclosures, (4) with thin metal enclosures, (5) thin-walled furnace with perforated walls, discontinuous working.

(6) as in 5 but continuous charge and moving furnace and (7) as in 6 but with fixed furnace. G.'s retort is continuous, fixed, vertical and indirectly heated, it has a thin charge, and heating wall of metal; the opposite wall is perforated and also of metal; gas is drawn off there; a sketch is given. He has treated lignites and shales in his retorts. The resulting oil is sepd. from ammonia liquors by decantation. He then obtains 5-10 l. very light spirit, 15-30 l. light and heavy spirit, 30-45 l. lamp oil, 5-15 l. heavy oil per ton lignite. The retort may be heated either by gas obtained, the oil obtained or pulverized fuel. G. discusses the economics of this process and its exploitation at some length.

S. L. B. ETHERTON

The national interest in low-temperature distillation of fuel. The French process of André Hereng. CH. ROZAK. *Chaleur ind.* 10, 55-63(1929).—R. summarizes the work done on the chem. constitution of solid fossil fuels. He discusses the mechanism of low-temp. distn., coking tar production and distn. products from brown and black lignites and different types of coals charting the yields. Consumption and production figures are given for France and the general position low-temp. processes would have in that country is discussed. In considering typical installations R. emphasizes the seriousness of dust entrainment in the tar. An account is given of the Rolle furnace used in Germany for distn. of moist Saxony lignites. A description is given of the Tozer retort and the tar yield therefrom is considered not very satisfactory.

S. L. B. ETHERTON

Low-temperature distillation of coal. A. LEAUTÉ. *Chaleur ind.* 9, 208-16(1928).—L. gives a summary of the work on coking from 1918, including the prepn. and treatment of Trent amalgams. L.'s app. consists of a gas-heated superheater to heat steam to 500°, 3 pots in series, each contg. a perforated sheet iron basket of about 6 kg. capacity, a deoiler and a condenser. Conclusion: (a) Flaming coals alone under different heat treatment cannot be prevented from caking and swelling and the manuf. of a synthetic anthracite from this type of coal appears impossible; (b) with anthracene oil as a binder, dense and hard agglomerates can be obtained even with flaming coals, and mixed fat and lean coals may also be used to obtain this synthetic anthracite; (c) the use of anthracene oil as a binder avoids swelling; (d) for mixed coals, the use of anthracene oil is not vital; pitch will do or the Trent amalgam. Some notes are added on the tar produced.

S. L. B. ETHERTON

Low-temperature distillation of coal by gas currents. F. A. OETKEN. *Z. Ver. deut. Ing.* 73, 229 32(1929).—The use of heated gas circulating through coal, which is to be heated to about 500°, has these advantages: (a) intimate heat exchange, (b) high efficiency, (c) exact regulation of temp., (d) economical treatment of the products of distn., (e) simplicity of operation, and (f) freedom from breakdowns of app. and interruption of operation. The Lurgi process (cf. C. A. 19, 2121) employs a blast-furnace type of construction, with a hopper feed, a pre-heating zone below it, a distn. zone, and then a cooling compartment. Gas-air mixt. burners send heated gas into the middle of the preheating or drying zone and the distn. section of the shaft; volatilized products pass through an elec. (Cottrell) tar separator, a condenser and a light-oil washer. Methods of operation will vary greatly with the properties of the coals used. Typical installations are shown, with units treating up to 200 tons of lignite or other fuel per day, and converting them into semi-coke. Various com. conditions make it difficult to give figures on operation costs, etc. For the brown coal deposits of Germany, with their high bitumen content, the process offers great promise. Built in conjunction with power plants, gas works for supplying large-scale demands, or for supplementing city gas, the Lurgi process proves useful.

W. C. EBAUGH

Low-temperature distillation of coal and the utilization of semi-coke. ANDRÉ KLING AND DANIEL FLORENTIN. *Chaleur ind.* 9, 217-21(1928).—A brief survey. Low-temp. tar is of little value and its disposal is difficult.

S. L. B. ETHERTON

The present state of the low-temperature carbonization of coal and lignite. CH. BERTHELOT. *Chaleur ind.* 9, 253-4(1928).—A description of an installation at Heinitz, Mines Dominiiales de la Sarre. Washed slime with 32% volatile matter and 21% moisture is dried. The semi-coke at 500° with 13-14% volatile matter is mixed with washed fines and by the heat the moisture is reduced to 8%. The duration of carbonization at Heinitz is reduced by 20%. In the Saar, 85 parts of bituminous fines of 30-32% volatile are mixed with 15 parts of semi-coke. This mixture is carbonized in the usual way; it gives metallurgical coke of a structure resembling that at Mines de Nord and at the Pas-de-Calais.

S. L. B. ETHERTON

Hydrogenation at high temperature and high pressure. ANDRÉ KLING AND DANIEL FLORENTIN. *Chaleur ind.* 9, 231-6(1928).—Pyrogenation of org. compds. gives rise to complex mixts. The conversion of hydrates to anhydrides, alcs. to lac-

tones, acids to hydrocarbons by elimination of the CO_2 group, belong to one class of reactions. The cracking of hydrocarbons belongs to a second class of reactions. The product of pyrogenation depends on the temp. and upon the duration of heating, the latter being often the dominating factor. Cracking is still largely empirical and coal distn. even more so. K. and F. hydrogenated naphthalene and anthracene, phenols, cresols, naphthol, with and without catalysts, indicate their results. Hydrogenation permits the sepn. of aliphatic from cyclic and polycyclic mols., particularly with the use of catalysts of the type MX_3 .

S. L. B. ETHERTON

Coal resources of the Black Hills region. C. C. O'HARRA. *Black Hills Engineer* 17, 49-61(1929).—The coal deposits of the Black Hills region are Lower Cretaceous and Early Tertiary, i. e., they may be lignite or subbituminous. The Lower Cretaceous beds are 3-10 ft. thick; squeezes, rolls and partings occur. The coal makes good coke in the beehive ovens. The volatile matter is about 37%, fixed C about 44%, moisture 2-7%, S 4.7-6.8%; as high; calorific value averages 10,700 B. t. u. The gold value of the coke averages, \$2.46/ton, this occurrence of Au being rare. In east Wyoming and S. Dakota are the lignites. Air-dried lignites showed 10-20% moisture, volatile matter 32-4%, fixed C 33-40%, ash 7-15%, S 0.7-3%, av. moisture of mine samples 38.5%, calorific value 8750 B. t. u. The various types of lignites occurring are described and analyses of 12 samples from northwestern S. Dakota are given.

S. L. B. ETHERTON

Testing coal at the Government Testing Institute of Sweden. EVERT NORDIN. *Intern. Congress Testing Materials* 1927, II, 674-83.—Between 3.5 and 4.5 million tons of coal is used per year in Sweden; about 90% of this is imported largely from England and Scotland. For the past 30 years the examn. of coal has been carried out by the Government Testing Institute and during the last 5 years the author has made a comprehensive revision of the methods and app. employed in testing fuels; he is aided in this work by a close personal study of the procedures used in fuel labs. in Great Britain and in the U. S. A. Outline directions are given of the approved methods for taking samples of coal shipments and prepg. them for analysis, and for detg. moisture, ash, m. p. of ash, volatile matter and fixed C, combustion for C and H, S, N, P and heating value. Special emphasis is placed on methods of sampling; the wt. of the raw sample must be in correspondence with that of the parcel of coal and the properties of the coal, especially its piece-size. Tables are given showing the wts. of raw sample to be taken from a given wt. coal shipment (i. e., 100 tons or less—large coal, at least 500 kg., smalls, about 200 kg., up to 1500 kg. large coal from a shipment of 2000 tons or over), for the assembling of the part-samples, for reducing the raw sample to a final sample by means of successive crushing and halving, and % differences in % ash found in general samples taken from the same parcel of coal; the largest % difference found was 0.36%. Moisture or water-percentage is detd. in 2 or 3 stages. If the coal is wet the whole of the general sample (10-100 kg.) is dried; if the coal feels dry after drying is performed to a max. of 30°. The air-moisture which remains after the drying is detd. by heating for 1 hr. in a drying oven at 103°. For oxidation during drying there is added for older coals 0.2% and for younger coals 0.5%; corrections are obtained by check detns. with drying *in vacuo* and xylene-distn. methods. Ash is detd. by combustion in a gas muffle furnace with final temp. of 775°, measured by a pyrometer. Expts. showed that the effect of final temp. on ash-value varies but little within the temp. interval 600-1000° except for coal whose ash contained large units of certain carbonates. There appears to be no general connection between the color of ash and its m. p., although gray-white ashes have often a high m. p. The crucible test is frequently made; it is a slightly modified A. S. T. M. test for volatile matter and fixed C. An ocular examn. of the coke is considered of practical importance, cokes being reported in graded values as: (1) powder, not sintered; (2) sintered, not porous; (3) sintered, porous to some degree; (4) caked, very porous, with blistered appearance. S is detd. in the coal by Bachka's method and in the ash according to Hillebrand. N is detd. by Kjeldahl's method, with CuSO_4 instead of Hg as the contact substance. Expts. showed that results with CuSO_4 agree within 0.02% N with those obtained by using Hg. This avoids using the fetid Na_2S , usually added to ppt. the H_2 . An extended investigation comparing detns. for % N in coal by Kjeldahl's and by Dumas' methods showed that results were likely to be somewhat low by Kjeldahl's and a little too high when Dumas' system was employed. With Dumas' method it was found necessary to analyze the gas collected, since it frequently contained CH_4 . If any other gases beside N. When both detns. were carefully carried out results checked within an allowable margin. Heating values are detd. in a Berthelot-Mahler calorimetric bomb on air-dried pulverized coal, unbricketed, placed in a Pt crucible so there is

good access of O, but no spraying of the coal powder, which is ignited by a cotton thread running from a resistance thread in the bomb lid into the coal. Gross and net calorific values are calcd. Tests have proved that the % H in the coals imported is proportional to the production of gross calorific value and content of volatile matter in accordance with the formula, $\% H = 3.0 + 0.007 K_b G_i / 1000$. Since 1910, there has been employed in Sweden, on an ever increasing scale, the practice of buying coal against a regulation in price in accordance with analysis and accompanied by a guarantee of mine certificate. The theoretical basis for a price-fixing system is developed: $W = [(K_b - 54 H_b) (100 - A_i) (100 - F) / 10,000] - 6F$, where W = net calorific value of the coal, K_b = gross calorific value of combustible substance in the coal, H_b = % H in combustible substance of the coal, A_i = % ash in the H_2O -free sample and F = % water. The final price-formula given is $p = k K_b (100 - f A_i) (100 - F)$, where p = price to be paid for the given shipment of coal, k = a const., basic price for the standard coal of fixed ash % in water-free sample, A_i and net calorific value of coal as delivered = W ; f = a correction factor of from 1.5 to 2.5, usually 2 applied to A_i . For % ash there is a fixed tolerance of $\pm 1\%$ and for effective heating value of ± 150 cal. within which limits the price cannot be altered. Additions or reductions in price are made for each 0.5% variation in % ash, and each 50 cal. above or below tolerance limits, with certain fixed limits below which the purchaser is entitled to refuse to accept the parcel. The technical and economic aspects of certain of the analytical methods adopted and of the price-fixing system are discussed. W. W. HODGE

Testing of coal and coke. W. B. CALKINS, A. C. FIELDNER, W. H. FULWELER, W. A. SELVIO AND O. O. MALLERIS. *Intern. Congress Testing Materials* 1927, II, 641-55.—The variety of conditions under which coal and coke have to be sampled make it impossible to follow any one method without some deviation, but application of certain general principles will increase the value of samples taken. Coal should be sampled by taking: equal increments from a great many equal parts of the original quantity; increments of such size that the largest lumps may be included; such a quantity that the largest pieces of slate or impurities will be insignificant in proportion to the sample; in such a manner that a true proportion of all sizes will be secured and taken blindly, so far as slate and impurities are concerned. The original sample should be reduced in such a manner that the discarded part is exactly like that retained; there will be no unaccounted-for loss or gain in moisture; no dust or other material will be blown away or lost through cracks in the floor; no foreign matter will get into the sample. The same principles apply in sampling coke, but since by-product coke is usually much more homogeneous than the av. coal smaller samples will suffice. A review is presented of the work from 1899 of different committees appointed in America to study and devise standard methods for the analysis of coal and coke. Procedures are outlined for the standard shatter test and vol. of cell space of lump coke. Proposed tentative standard tests are given for the sieve test for detg. the size and uniformity of the coke pieces; the cu. ft. wt. test; and the hardness or tumbler test, designed to give a relative value for the resistance of coke to mechanical attrition in the blast furnace. The practical significance of results obtainable in these tests is stated. At present the results of the proximate analyses are relied upon for the preliminary information regarding the valuation of a gas coal. The gas coal should contain at least 35% volatile matter calcd. on the ash- and moisture-free basis; the ratio of fixed C to volatile matter, while not always a reliable index of the type of coal, should generally be between 1.4 and 2 for a gas coal and between 1.4 and 5.0 for coking coals. The moisture is a further rough check on the type of coal. If not subject to agreement by purchaser and seller, the mine moisture in the coal as mined should not exceed 4.0%. The ash in the dry gas coals should not be over 7%. The fusing temp. of ash of coals, for making domestic or industrial coke should not be below 2200° F.; for the coke to be used for manuf. of water gas the fusing temp. of the ash should preferably be higher than 2300° F. The compn. of the coal shall be such that the dry coke produced therefrom contain not over 1.5% S and the resultant gas contain no more than 30 grains of S in the form of compds. other than H_2S per 100 cu. ft. of gas. Gas coal shall produce a coke of sufficient size and strength to be suitable for domestic use or in the manuf. of water gas. A knowledge of the rank of the coal and its ultimate analysis is also helpful in judging as to probable characteristics of the gas, coke, tar and by-products it will produce upon carbonization. Various tests devised to give directly the yield of gas, coke, tar and ammonia are outlined and their relative value discussed. Utilization for exptl. purposes of 1 or more full-sized retorts of the type to be used industrially, or of lab. tests such as that developed by the U. S. Steel Corporation for detg. the by-product value of coals where suitable factors detd. by experience are applied to the lab.

data will probably give the nearest approach to results which will be obtained from large-scale operation. However, it is necessary that coal should be treated in large-scale app. under commercial operating conditions before one can be assured of its commercial value for gas manuf. A short general discussion follows the article. Many references to the literature on and to A. S. T. M. methods for sampling and analyzing coal and coke are given.

W. W. HODGE

New methods of investigating coal and coke. K. BUNTE. *Gas u. Wasserfach* 72, 124-7(1929).—At the Gasinstitut the following detns. are made on coal and coke: (1) ash detn., (a) cone m. p., (b) fusion curve of ash; (2) moisture detn.; (3) coking tests (a) "bubbling" test, (b) coking properties, (c) heat of coking, (d) detn. of percentage of coke-forming constituents; (4) volatile constituents; (a) calorific value of gas from gas coals, (b) distn. tests for coals to be used for low-temp. distn.; (5) reactivity of products of coking; (6) ultimate analysis. The tests are discussed critically and a bibliography is given.

R. W. RYAN

Why does coal coke? WILBERT J. HUFF. Johns Hopkins Univ. *Am. Gas J.* 130, No. 3, 40-3(1929).—Discussion of our present knowledge of the constitution of coal and the relation of this to its coking properties.

Studies in the auto-combustion of coal. II. An observation of the characteristics of coal combustion. JIROSAEMON INABE, ICHIRO MIYAKAWA AND TO YAMADA. Kyushu Imp. Univ. *Bull. Tech. Dept. of Kyushu Imp. Univ.* 3, 210 7(1928).—Powdered coal was treated adiabatically with a definite quantity of O_2 gas and the rate of temp. rise $d\theta/dt$ was measured between 85.8° and 128.7°. This was substituted in the K of Arrhenius expression, $\ln K_1 - \ln K_2 = a[(1/\theta_1) - (1/\theta_2)]$, and after some transformation there was obtained the expression $\theta + a \ln \theta - (1/2)(a^2/\theta) - (1/2)(3)(a^3/\theta^2) - \dots - 1/((\gamma - 1)(\gamma)(a\gamma/\theta^{\gamma-1}) - \dots = K_1 + K'$, where K and K' are const. Calcn. showed that the temp. rises in 15 mins. at 22.5°, 52.5°, 82.5°, 112.5°, 142.5°, 172.5°, 202.5° and 232.5° are, resp., 0.005°, 0.07°, 0.3°, 1.4°, 5.2°, 16.4°, 78.1° and 208.3°. K. SOMEYA

Recent processes for the dry concentration of coal. W. BR. GUTACKER. *Montan. Rundschau* 21, 81-6(1929).—Dry concentrators for coal (and ore) work upon one of 3 principles, viz., concg. tables provided with a const. or intermittent air current; centrifugal force; or mixt. of air and sand. Descriptions and explanations are given for the Sutton, Steele and Steele concentrators developed in Texas and now used by the Birtley Iron Co. in Durham, England. Close classification of feed is necessary, but with the American Coal Cleaning Corporation's concentrator, provided with a Y-shaped table, greater variations in feed sizes are possible. Other concentrators of the same general type are those of Roberts and Schaffer Co., Chicago; Hugh Wood Co., Newcastle-upon-Tyne; Peale, Peacock and Ken Co., St. Benedict (Pen) and Woodall Duckham Co., London. With the Peale-Davis machine of 2 × 10 m., with an air consumption of 2000 cu. m./min., 100 tons per hr. can be treated. Pollock's and Pardee's spiral separators permit coal to flow down spiral chutes in such a way that the coal and refuse are sepd. by reason of their different coeffs. of friction. Such a separator 3-4 m. high and 1.5 m. in diam. has a capacity of 12 tons/hr.; many have been put into commission recently. In the Ayres concentrator coal is fed upon rotating plates, and in Mackley's belt concentrator it falls upon a tilted belt with roughened surface; in each case the sepn. is due to differences in friction coeffs. of coal and culm. The Bettisford concentrator depends upon the different elasticities of coal and gang; such a separator requiring 1.75 × 1.75 m. floor space can treat 15 tons/hr., but only with pieces of a min. size of 5 mm. Frazer-Yancey concentrators employ an air-sand mixt. of sp. gr. about 1.45 upon which the coal floats and through which the waste sinks; by sieving the sand is then recovered. This process does not have a wide adoption just now. Dry processes are better than wet in that the coal is left in a dry condition ready for shipment, briquet making, etc. On the other hand, coal contg. 3-4% admixed moisture must be dried before it can be dry-concd., the fire hazards are great, etc. Dry-concg. processes must be considered as still in the exptl. stage. A process of the Iron and Steel Smelting Co., Bochum, employs a combination of air currents on a veil of falling coal so regulated as to give good sepn. into different sizes and sp. gr.

W. C. EBAUGH

The pneumatic tables of Sutton, Steele and Steele in the mechanical preparation of coal and the consequent advantages. R. GUGL. *Chaleur ind.* 9, 63-7(1928).—The "Wye" separator is described. Superficial moisture does not matter in pneumatically sepg. coal larger than 3 mm. but is of the greatest importance in screening. Dust above 0.4 mm. is blown into sack filters. Dust is the chief problem in the dry cleaning of coal but the difficulty here is really the utilization of the collected matter. G. gives

2 tables showing ash content of various sized coals and considers advantages to the mine, the different industries and in coke and gas manuf. S. L. B. ETHERTON

Considerations of the present state of technic of pulverized coal. F. HORSARD. *Chaleur ind.* 9, 99-103(1928).—Most pulverizers are tube mills (Bonnot) or vertical pulverizers (Fuller-Raymond) of slow speed and the pulverized coal is sent directly to large hoppers before being transported to secondary hoppers at the point of consumption. The fuel before pulverizing is dried to 1% moisture. Individual pulverizers used at the point of consumption are almost universally high-speed impact machines and the coal is not dried but has a moisture content of 5% or exceptionally 7-8%. F. deals with the prepn. of the material for pulverizing and points out the recent tendency of reverting to individual pulverizers rather than to a central pulverizer. The tendency is to reduce combustion space and to reduce the size of the coal flame. To this end, air preheating and pronounced turbulence are of much help as is artificial cooling of the furnace walls. H. considers various methods of abating the dust emitted from chimneys of pulverized coal installations. S. L. B. ETHERTON

Oil recoveries from English coals. J. IVON GRAHAM. University of Birmingham. *Oil & Gas J.* 27, No. 31, 147(1928).—A review of recent expts. on the recovery of oil from the various constituents of coal by hydrogenation shows that the hydrogenation products vary with the type of coal used. Dried clarain dust hydrogenated at 420° and 124 atm. showed no considerable amt. of oil, the results showing that the initial reaction is one of removal of O₂ which may be removed by distn. with N and H. Suspension of the coal in phenol (2:1) and hydrogenating with or without catalysts in a 3-l. autoclave shows a final H pressure of 23 atm. as against 35 atm. initial pressure and when with N an initial pressure of 38 atm. and a final pressure of 41 atm. An analysis of the products of reaction in each case shows that in most coals an increase of oil content is obtained on hydrogenation. Parabittuminous coal gives best results. Gaseous products show an increase in every case except brown coal, which is probably due to cracking. On catalytic hydrogenation of coal, 3-10% phenols are formed. Although the original Bergius patents claimed non-catalytic hydrogenation, it is known that an Fe compd. is used ostensibly for the purpose of removing S. A study of catalytic hydrogenation using 5% FeO produced an increased yield of 2-3% oil. NiO is a better catalyst. Finely ground coal produces about 4% more oil than a noncoking coal. Boghead and cannel coal cannot be hydrogenated to give increased yields of oil. M. B. HART

Sorption of pyridine vapor by coal from Upper Silesia and by its petrographical modifications. W. SWIENTOSLAWSKI AND M. CHORAZY. *Bull. intern. acad. Polonaise* 1928, 361-5.—See C. A. 23, 953. ALBERT L. HENNE

Coal gasification in producers. FRITZ MORAWSKI. *Wartberg-Mürztal. Gas u. Wasserfach* 72, 149-54(1929).—Gasification of coal in a gas producer using (a) air alone, (b) air with water vapor and (c) air with water vapor and flue gas is discussed from a theoretical standpoint, giving theoretical gas and flame temps. When the gas is to be used hot, air alone is best, but when cold gas is to be burned, gasification with moist air is preferable. Warm water, heated by waste heat, is better than steam for humidifying the air blast. A saving of 5 to 7% of the coal may be realized by humidifying the air and humidification will also cause an increase in heating value of the gas. R. W. RYAN

Determination of the calorific value of coal from the proximate analysis. R. KATTWINKEL. *Teer u. Bitumen* 27, 49-52(1929).—The classification of coals and calcn. of their calorific values from their proximate analysis are discussed with extensive bibliography and data. The Goutal and König formulas are cited as the best, and the latter is recommended as giving very close approximations. F. S. GRANGER

The determination of the calorific value of brown coal by calculation. KARL D'HUARI. *Braunkohle* 27, 825-32(1928).—The various known methods are reviewed, with references. Three types of formulas exist, the first of which is based on elementary analysis, the 2nd on crucible analysis and the 3rd on the quantity of O₂ consumed in combustion. Of the first type, the Dulong formula gives uncertain values for brown coal. Better results are to be expected with the Vondrazek formula, since it is founded directly on expt. and checks other formulas based on expt. The Berthier method of the 3rd type, whose practicability has always been doubted, although based on unscientific assumptions, was found on trial to be not so inexact as has often been indicated by unfair comparison with the unsatisfactory Dulong formula. With the formulas based on crucible analysis, discrepancies of considerable magnitude between expt. and calcn. were obtained. If information on the coal field from which the specimen came is available, it is possible to det. the calorific value of the raw coal with

accuracy from the known calorific value of the pure coal and the moisture and ash content.

F. S. GRANGER

The gasification of Rhenish brown coal. HERMANN BECKER. *Braunkohle* 28, 121-6(1929).—The best working conditions, with reference to grate residues, piping, regulation and measurement of blast and gas pressure and flow, dust in gas and tar, hot vs. cold gas, tar, etc., are summarized.

F. S. GRANGER

Trials of a wood producer fed with peat. ALAIN LEMONNIER. *Chaleur ind.* 9, 289-92(1928).—Different results were obtained in the Valet producer by using granulated or straight peat. L. deduces that the calorific value of a fuel is insufficient to evaluate a fuel. L. favors the granulation process of Charles Roux, this giving better products in the producer. Crude peat is a very bad conductor, difficultly inflammable, but is very reactive, once it has been carbonized.

S. L. B. ETHERTON

Results obtained from the combination of a Sauvageot grate and a Siemen's producer. E. WIBRATTE. *Chaleur ind.* 9, 293-9(1928).—Such a combination (s) and a plain Siemen's producer (p) were run on the same fuel. The gas produced had (s) 3% CO₂, 0.7% O₂, 28.2% CO, 10.4% H₂, 55.6% N₂; (p) 9.6% CO₂, 1.2% O₂, 18.9% CO, 4.8% H₂, 64.7% N₂. The gas exit temp. (s) 700°, (p) 800° (the inlet air temp. being the same in each case), secondary air (s) 700°, (p) 800°; calories lost in ash (s) 74, (p) 587; lower calorific value of the gas (s) 1304, (p) 772; heat utilized (s) 82.6%, (p) 55-6%.

S. L. B. ETHERTON

Operating conditions of fused-ash producers and a comparative thermal balance. DESSEMOND and MAYENÇON. *Chaleur ind.* 9, 272-7(1928).—From shale contg. 50-60% ash, coke with 28-30% fixed impurity, some lime, etc., the gas obtained had a calorific value (lower) of 1200. Analyses of the slag and of the melt are given. The thermal balance is analyzed; the yield is 71.6%. The fused-ash producer is compared with (a) the blast furnace, (b) the ordinary producer of the steel works, (c) the special producer of Montrambert, with slow operation, automatic discharge, strong injection of steam and working on high-ash coke. The fused-ash does better than (a) and (b) but is just under (c). The question is also treated theoretically and the conclusions are that as regards the temp. of combustion, dry and warm draft is better than steam draft. If the temp. of combustion of the resulting gas is required to be higher, it is most economical to mix it with coke-oven gas. Theoretically the yield from the fused ash producer is good, but in addition it should be remembered that the fuel used contains about 50% ash, usually valueless. Working the producer on valueless shale gives enough heat for a warm blast for the blast furnace and also leaves a surplus heat. The discussion elucidates points in the paper.

S. L. B. ETHERTON

Recent improvements in producers for industrial gases and general installations of producers. M. GUÉRIN. *Chaleur ind.* 9, 278-81(1928).

S. L. B. ETHERTON

Study of gasification and the practical operation of producers. H. GUILLOU. *Chaleur ind.* 9, 581-7(1928).—A review of previous work shows that the theoretical study of the equil. conditions of C and its oxy compds. has given inadequate results. Steam injection has the advantage of lowering the temp. of the fuel bed, thereby avoiding fusion of the ash, converting sensible into latent heat, and it raises the calorific value of the gas. G. simply considers the production of CO, CO₂ and H₂ in the producer. Two qualities of mixed gas can be obtained (a) high in CO and N₂ and low in CO₂, (b) high in CO₂ and H₂ and low in N₂; the former has the higher calorific value, but is more difficult to make. Not all the steam injected is decomposed, the question of steam injection being considered at some length. The fuel bed is to be uniform in thickness, the fuel should be added evenly and ash should be regularly and evenly removed. The fuel should be well graded, with minimum fines. Combustion, blast and draft, should be uniform and well adjusted. Depth and surface pricking are taken up.

S. L. B. ETHERTON

Research—and a greater gas industry. ARTHUR D. LITTLE. *Am. Gas. Ass. Monthly* 10, 661-5, 682(1928).—The tremendous progress made by the electrical industries—lighting, power, the telephone, electric refrigeration, radio, television—is credited as the direct product of unremitting research. The technical, economic and publicity advantages to be gained by the gas industries cooperating with chem. research are mentioned. A no. of recent results of chem. research involving utilization of gas plant products are discussed: the gas-fired refrigerator, with the possibility of space cooling of homes, offices and factories, solid CO₂, the use of water gas in the synthesis of motor fuels, methane and other paraffin hydrocarbons, ammonia, methanol and other alcohols; and manif. of light oils and motor spirit by hydrogenation of coal and vapor phase cracking of gas oil. The beginnings of a great chem. industry based on natural gas are evident from the already achieved common production of ethylene

dichloride, ethyl chlorohydrin, ethylene glycol, amyl chlorides, alcohols and acetates. The energy-carrying capacity of a gas company's distribution system could be more than doubled by converting the blue water gas (300 B. t. u./cu. ft.) to methane (1000 B. t. u./cu. ft.) and a non-poisonous gas be thus supplied. If the CH_4 were mixed with 20% O_2 , the flame temp. would be raised about 10%. The present status and costs data for several of the processes are given. The creative power of research and its great possibilities when effectively applied to the gas industries are emphasized.

W. W. HODGE

A study of natural gas. K. STOCKFISCH. *Petroleum Z.* 24, 907-10(1928).—See C. A. 22, 4772.

M. B. HART

Chemical composition of Polish natural gases. K. KLING AND L. SUCHOWIAK. *Petroleum Times* 20, 919(1928); cf. C. A. 22, 4772.—The analyses of samples of natural gases from various districts and wells are given. The Jaeger-Ubbelohde-Czako method of analysis is used.

M. B. HART

The determination of low percentages of hydrogen sulfide in gas. H. BACH. *Gas u. Wasserfach* 72, 154-5(1929).—The usual methods of detg. H_2S in gas by gas analysis or by reaction with KI are not applicable to very small percentages of H_2S . B. passes 2 l. of gas, held over satd. (acidified) NaCl soln., through 25 cc. of 10% NaOH soln. in an inclined bubbling tube at the rate of approx. 1 l. per hr. The NaOH soln. is then diluted quantitatively to 100 cc. and a 10 cc. portion tested with 1 drop of alk. Pb acetate soln. (25 g. K Na tartrate, 5 g. NaOH , and 1 g. Pb acetate made up to 100 cc. with distd. water). If a strong brown color results, 10 cc. of the diluted sulfide soln. is made up to 100 cc. in a glass cylinder (Nessler tube) and 5 cc. of the Pb acetate soln. added and the soln. mixed well. Five cc. of the Pb acetate soln. and 95 cc. of distilled water are placed in a similar cylinder. As_2S_3 soln. (24 mg. per 100 cc.) is then added drop by drop with stirring until the color matches that of the unknown soln. One cc. of the As_2S_3 soln. is equal to 0.1 mg. of H_2S or 0.065 cc. at 0° and 760 mm. pressure. It is suggested that the As_2S_3 be prepd. in 1 g. tablets contg. 24 mg. As_2S_3 and 976 mg. anhyd. Na carbonate as these tablets are stable if kept in a dry dark place, while the soln. decomposes quickly.

R. W. RYAN

The manufacture of carbureted water gas. A. BARRIL. *Chaleur ind.* 9, 257-71 (1928).—B. studied the cracking of gas oil in a quartz tube electrically heated to 500° , 550° , 600° , 650° , 700° , 750° , 800° , 900° . The app. included means to catch tar, H_2S and naphthalene and a meter and gasholder. Cracking commences at 500° with a const. gas increment to 900° . The calorific value falls off, however, and the thermal yield increases to 650° and remains about 60-55% between 650° and 900° . At 700° there is much C_2H_4 . The tar yield falls with temp. but the density increases, the free C rapidly increases between 800° and 900° , while toluene and xylene fall off. Naphthalene is a max. at 750° . These results are clearly set out in curves and tables. To study the cracking of gas oil in the presence of blue water gas required a more complicated app.; a sketch is given of it. The results show that the thermal yield point is unchanged but yield is augmented. Max. yields are obtained by carburting between 650° and 690° ; naphthalene is max at 750° . Industrially it is desirable to crack between 650° and 700° . Cracking is endothermic. From the very numerous data in this paper and the price of gas oil the best working conditions can be calcd.

S. L. B. ETHERTON

The manufacture of low-gravity carbureted water gas. LEON J. WILLIEN. Bylesby Eng. Corp., Chicago. *J. Western Soc. Eng.* 34, 83-95(1929); cf. C. A. 22, 1226.—Mixing water gas with coal gas to care for peak production results in a marked variation in sp. gr. which frequently causes trouble in burner adjustment. Introducing 1.5 gals. of oil per M. into the top of the superheater during back runs decreased the CO_2 and increased the H_2 production, thus decreasing the sp. gr. to within the tolerance for coal gas (0.52) without reducing the B. t. u. The capacity of the set was increased 51% when using coal and 23% when using coke and the generator fuel was reduced from 29.7 to 21.9 per M. Introducing the oil into the carburetor was not satisfactory because of the failure to crack; introduction into the superheater was successful.

A. S. C.

Burning of coke breeze and blast-furnace gas under steam boilers. R. C. DUNOV AND OTTO DE LONNIZ. *J. Western Soc. Eng.* 34, 177-90(1929).—A no. of typical installations are described for burning (a) coke breeze alone, on travelling chain-grates; (b) lean blast-furnace gases, both dirty and cleaned; and (c) combinations of coke breeze and blast-furnace gases. The combination furnace has proved practical, its outstanding advantage being that it permits one boiler to be used for 2 kinds of fuel whose supply may vary greatly. In general, there is a practical advantage in locating both stoker and burner at the operating floor level, but this need not be the case when a

rear arch type of furnace is used. The type of furnace selected will be governed by the location of breeze bunkers, gas mains, type of boiler and ash-handling equipment. It is most desirable to have sep. furnaces for stokers and burners, with an adequate wall interposing to protect one from the other. In addn. there should be a large common combustion chamber located at and under the first bank of boiler tubes, and above the 2 sep. furnaces. Preheated air should be employed, especially with gas burners.

W. C. EBAUGH

The chemical utilization of coke-oven gas. VALLETTE. *Chaleur ind.* 9, 319-27 (1928); *Metallbörse* 18, 1856 (1928).—Coke-oven gas, after cleaning, etc., has the compn. by vol., H_2 50%, CH_4 25.2%, CO 7%, C_2H_4 1.2%, C_3H_8 0.3%, C_4H_{10} 0.5%, CO_2 2.6%, N_2 13%. H_2 can be removed and converted into NH_3 and thence into $(NH_4)_2SO_4$. The H_2 can also be converted into HNO_3 , NH_4NO_3 , etc., and also used in hydrogenation. The N_2 can be recovered but more will be required to be added if NH_3 is made. Since CO is a strong poison in NH_3 catalysis, its removal must be rigorous. Various methods are cited for the conversion of CO into alcs., aldehydes, etc., and the subsequent production of org. derivs. Divers cracking methods for CH_4 are considered and also the action of Cl_2 to obtain chlorohydrocarbons and of O_2 . It would be comparatively easy to remove C_2H_4 as its b. p. is -105° and it could be converted into $EtOH$ by absorption in H_2SO_4 or into Et_2O or Ca acetate or Et acetate. Reference is also made to working up into indigo and novocaine *via* ethylene chlorohydrin. C_3H_8 is converted into iso- $PrOH$ by the Standard Oil Co. and probably a similar process can be used by the coke-oven industry. This alc. is preferable to $EtOH$ in the perfume industry as having a more delicate odor. C_4H_{10} has not yet found extensive utilization. CO_2 is not utilized at present in the gas industry, but it may be easily removed and used in $(NH_4)_2CO_3$, $(NH_4)_2SO_4$, and urea manuf.

S. L. B. ETHERTON

Petroleum wash-oil thickening in the scrubbing of coke-oven gas. H. M. ULLMANN, D. S. CHAMBERLIN, C. W. SIMMONS AND M. A. THORPE. *Ichigh Univ. Ind. Eng. Chem.* 21, 313-4 (1929).—Heavy oil used to absorb light oils from coke-oven gas slowly increases in sp. gr. and "thickens," with reduction in absorptive capacity. This has been proved due to tar suspended in the gas which was pptd. by means of Cottrell pptn. The tar is high in S; hence the erroneous belief that S might be the cause of thickening. Coke gas contains 3.17 g. per cu. ft. of this tar.

A. S. CARTER

Corrosion of gas holders. J. S. THUNISSEN, JR. *Helv. Gas* 49, 104 9 (1929).—Expts. were made on the corrosion of iron plates in rain water and in gas holder water, the plates, exposed to air, were repeatedly moved up and down during periods of 1 to $1\frac{1}{2}$ years. When the plate was covered with "Imunol," a special paint oil used for protection of holders, practically no attack occurred; very little corrosion was found if a neutral engine oil were used instead. The water of the holder basin (contg. some cyanide) acted more vigorously than rain water; per sq. cm. surface 0.19 and 1.26 mg. of the material dissolved, resp. Plates hung up for 1 year in the holder tank at various elevations showed increased corrosion closer to the water surface. Inside the bell lubricating oil protected iron plates completely against corrosion.

B. J. C. VAN DER HOEVEN

Applications of centrifugal machines to various problems in gas transport. M. FARACCI. *Chaleur ind.* 9, 300 8 (1928).—The construction and details of multicellular centrifugal blowers are described and a longitudinal section is given together with a photograph of a winged extractor disk. The use of such machines for extn. of coke-oven gas is considered in some detail. The construction of monocellular extractors with radial vanes is described and their application to tar removal from gases is considered. The use of these machines in long-distance, high-pressure transmission is dealt with, and the handling of high-temp. steam and gas.

S. L. B. ETHERTON

The internal-combustion engine. Its working conditions and its eventual application to aviation. MAURICE ROY. *Chaleur ind.* 10, 11-8 (1929).—The development of the application of superheated steam and internal-combustion engines led to the study and use of special metals and alloys to withstand higher temps. Metals and alloys for an internal-combustion engine suited for aviation should be able to resist $800-1000^\circ$ at the turbocompressor exit, $1200-1400^\circ$ in the combustion chamber, and $700-860^\circ$ at the exit of the first distributor of the turbine. R. considers kerosene to consist of 40% $C_{12}H_{22}$, 25% $C_{14}H_{30}$, 15% $C_{16}H_{34}$, 20% $C_{18}H_{38}$, and, using Mallard-Le Chatelier and Pier-Bjerrum sp.-heat values, he calcs. the theoretical results obtainable under various cycles of operation and then discusses which conditions are feasible. If the degree of diln. of the combustion products be 300% and the degree of compression be between 5 and 45, then the degree of diln. will be almost 3 times that of the Diesel at 45 kg./sq. cm. Such diln. means added size and wt. To improve efficiency it will

be necessary first to improve the turbocompressor and also hot gas turbines. R. then discusses the requirements for aviation conditions. S. L. B. ETHERTON

The production and utilization of benzene in France. R. BRUNSCHWEIG. *Chaleur ind.* 9, 311-8(1928); cf. C. A. 22, 3760.—Production statistics for France, Germany and Great Britain are given. Utilization as a motor fuel is discussed. S. L. B. E.

Utilization of propane and butane. R. W. THOMAS, Phillips Petroleum Co., AND O. M. SETRUM, Philfuels Co. *Oil & Gas J.* 27, No. 22, 330, 332, 334(1928).—A survey of the properties and possible uses of natural-gas constituents indicates that at the present low gas-oil price levels butanes seem competitive at a common price per gallon for water-gas enrichment, and that this value will increase. Practical handling methods have been devised. The liquefied gases offer a potential sole raw material for economical gas manuf. M. B. HART

Determination of the calorific value of Diesel oil. F. V. WARNOCK. *Engineering* 126, 418(1928).—Satisfactory detns. of the calorific value of Diesel oil were made in a Darling calorimeter by absorbing the oil in kieselguhr before combustion. From 0.75 to 1.5 g. oil mixed with twice its weight of powd. kieselguhr gave the best results. Somewhat low values were given by this method because of heat losses from the calorimeter, but a control combustion with an oil of known calorific value provides a correction factor. J. W. SHIPLEY

Study of coke formation. R. A. MOTT AND TADAJI SHIMMURA. *J. Fuel Soc. (Japan)* 8, 172-90(1929).—See C. A. 23, 1247. F. I. NAKAMURA

The chemical control of boiler plant (RIDLEY) 14. Squandering fuel in commercial plants employing heat (GRAULICH) 13. The operation of Siemens-Martin furnace with coke-oven gas (BULLE) 9. ARMSTRONG, J.: **Carbonization Technology and Engineering.** London: Charles Griffin and Co., Ltd. 36s. net.

Burning granular fuel. AUGUST FARNER. Ger. 471,325, Nov. 27, 1924. Incompletely consumed fuel is re-ground and returned to the combustion chamber.

Burning fuel of uneven particle size. GERTRUD FRANKE GEB. MOHNICKE, WOLFGANG FRANKE and CHRISTA RUHE GEB. FRANKE. Ger. 471,101, Nov. 25, 1924. Means are described whereby the fuel is winnowed on its way to the furnace and the fractions so obtained are fed separately and simultaneously to the furnace.

Agglomerating solid fuels. J. PINTSCH A. G. Brit. 295,327, Aug. 9, 1927. Pulverulent fuel such as brown coal is agglomerated in moist condition by subjecting it to a rotary motion such as may be given by a rotary cylinder which is slightly tilted.

Rotary retort apparatus (with internal shelves) for heating and distilling carbonaceous or other solid materials. H. NIELSEN and B. LAING. Brit. 295,755, May 18, 1927. Various structural details are specified.

Liquid fuel. EMILIO M. FLORES. Fr. 646,775, May 20, 1927. A liquid fuel is obtained by distg. products of any alc. or other fermentation along with carburants such as crude petroleum distn. products of mineral oils or coal, or synthetic carburants such as "tetralin," "decalin," "synthol," "synthene," "ketol," etc. Cf. C. A. 22, 1031.

Motor fuel. PAUL GIRARD, FERNAND PETIT and ALBERT CHARBONNEAU. Fr. 646,439, May 16, 1927. A fuel suitable for motors is obtained by reacting on the volatile substances or on the solid fuel itself in low-temp. distn. with a halogen or halogen acid or substances which liberate them on heating.

Fuel for internal combustion. LESTER KIRSCHBRAUN and CHARLES B. BELKNAP. U. S. 1,707,019, March. A relatively permanent emulsion is formed of

naphthenic acid, water and distillates comprising a mixt. of the gasoline, kerosene and gas-oil content of crude petroleum, in which the water is in the dispersed phase and the oil in the continuous phase. The distillates comprise at least 70% by volume of the product.

Vertical retort construction for low temperature carbonization of fuel. C. TURNER. Brit. 295,461, May 31, 1927. The charge is supported by a plurality of intermeshing vertical screws which also constitute a discharge device for the residual coke. Pipes are provided for the supply of superheated steam to the charge and for leading off gas, and various structural details are described.

Destructive hydrogenation. DEUTSCHE BERGIN A.-G. FÜR KOHLE- UND ERDÖL-CHEMIE (Arno Debo, inventor). Ger. 469,867, June 11, 1924. See U. S. 1,764,792 (C. A. 23, 2022).

Destructive hydrogenation. I. G. FARBENIND. A.-G. Brit. 295,947, Aug. 7, 1926. Metals of the 5th, 7th or 8th group of the periodic system or their compds. together with Al or its compds. are used as catalysts in destructive hydrogenation of carbonaceous materials. Brit. 295,948 specifies the use of U or its compds. together with elements of the second group of the periodic system or their compds. Brit. 295,949 specifies U or its compds. together with Al or its compds. as catalysts.

Destructive hydrogenation of carbonaceous materials. I. G. FARBENIND. A.-G. Brit. 295,587, Aug. 9, 1926. Destructive hydrogenation of coals, tars and their products is effected under a pressure of at least 20 atm. (and preferably 50 atm.) in the presence of a catalyst, consisting of Pb or Sn or their compds., on supports of magnesia or magnesite alone or mixed with other suitable substances.

Destructive distillation. ANTONIO G. PULT. Swiss 128,188, May 6, 1927. A still for the dry distn. of lignite comprises a straight chamber mounted at an angle to the furnace so that volatile products can escape at the upper end and liquid products at the lower end.

Distilling carbonaceous materials. ARTHUR M. A. STRUBEN. U. S. 1,706,468, March 26. Solid carbonaceous material to be distd. such as torbanite, oil shales, coal, brown coal, peat, lignite or tar sands, in comminuted form, is suspended in a hydrocarbon material such as a heavy oil or paraffin maintained in bulk in an enlarged zone and having a higher b. p. than that of the desired distillate of the solid carbonaceous material and heat is supplied directly to this zone and distn. is effected at as high a temp. as possible without distg. the bulk of the carrier material; the suspension is agitated, the distillate is removed, and the solid carbonaceous material remaining undistd. together with the hydrocarbon carrier allowed to settle in a separate zone, so that the carrier may be further used in the process. An app. is described.

Apparatus (with superposed material trays) for distillation of solid carbonaceous materials. F. M. SALERNI and METALLBANK UND METALLURGISCHE GES. A. G. Brit. 296,108, Feb. 25, 1927. See Can. 283,205 (C. A. 22, 4234).

Charging device for destructive-distillation retorts. AKT.-GES. DER MASCHINENFABRIK VON LOUIS GIROND. Swiss 127,745, Aug. 9, 1927. The device runs horizontally and has a suction app. to remove dust.

Vacuum system of flotation separation of coal, ores, etc. FRANK E. ELMORE. U. S. 1,706,281, March 19. An app. is described.

Apparatus for drying coal, etc. F. S. TUCKETT. Brit. 295,476, June 23, 1927. The material is passed over a series of superposed horizontal rotary plates co-acting with stationary scrapers and spreaders. A magnetic separator is arranged to separate iron from the material before it passes through the app.

Burning powdered fuels such as coal. RAY C. NEWHOUSE (to Allis-Chalmers Mfg. Co.). U. S. 1,706,300, March 19. The fuel and air are injected into a combustion chamber where the fuel is burned in suspension; the combustion products are mixed with combustion products, the temps. of which have been somewhat lowered, and this mixt. is passed through a heat-transfer device such as tubular steam boiler. An arrangement of app. is described.

Coking coal. SOC. ANON. D'OUGRÉE MARHAYE. Brit. 295,314, Aug. 9, 1927. Coals purified by a process such as is described in Brit. 295,312 (following abstract) so as to reduce their ash content to less than 1% are coked (suitably after briquetting with or without addn. of a binder) in a vertical or horizontal retort in which they are subjected to a current of highly heated fluid such as steam or N. Coke suitable for electrode manuf. may be thus obtained.

Purifying coal. SOC. ANON. D'OUGRÉE MARHAYE. Brit. 295,312, Aug. 9, 1927. A coal contg. less than 1.25% ash is reduced to granules of less than 10 mm. diam. and the coal is wetted by a succession of liquids of gradually increasing strength (such

as CaCl_2 solns. following a preliminary wetting with water) so that sepn. is finally effected by the "float-and-sink" method. Cf. C. A. 23, 1249.

Distilling coal or other solid carbonaceous fuels. WALTER E. TRENT (to Trent Process Corp.). U. S. 1,706,420, March 26. A plurality of heating mandrels in a retort are surrounded by the fuel to be distd. and these mandrels may be heated by combustion gases to effect distn. and carbonization. Details of the app. are described. U. S. 1,706,421 describes structural details of an app. with superposed hearths and rabbles for distg. carbonaceous materials such as coal or coal and oil mixts.

Apparatus (with superposed vertical retorts) for distilling coal, etc. PAUL DVOROKOVITZ. U. S. 1,706,825, March 26. Material such as coal is fed into the top of the upper retort, which is provided with an agitating device, and thence, through a valved connection into the lower retort; gas is supplied to the upper part of the retort chambers and gas outlets are provided at the bottom of both the upper and lower retort chambers. Various structural details are described.

Rotary drum apparatus for low-temperature distillation of coal, shale, oil, tar and carbonaceous refuse. J. H. ANDERSON. Brit. 295,503, July 25, 1927. The drum used contains loose metal bodies which free the drum from adhesions and serve also as heat distributors to the charge. Flanges extending inwardly from the walls of the drum (which is slightly inclined to the horizontal) serve to retain these metal bodies and keep them properly distributed throughout the drum. Various structural details are described.

Molding peat and the like. BOHUMIL JIROTKA. Ger. 466,987, Mar. 23, 1922. The method in which the peat, etc., is disintegrated and pressed into a continuous length, the length cut up and the pieces molded, is modified by sprinkling the cut pieces with dust, *e. g.*, coal dust, before the molding.

Montan wax. I. G. FARBENIND. A.-G. Brit. 296,145, June 9, 1927. Montan wax which has been bleached by oxidizing agents such as Cl , chromic acid, or air and HNO_3 , is treated by esterification or otherwise to convert the free org. acids at least in part into esters, metal salts, anhydrides, amides or their substitution products or ketones or other substances contg. the group $-\text{CO}-$ but not the group $-\text{COOH}$. A wax is thus obtained which does not crystallize and which is especially suitable for use in leather polishes or floor polishes. The treatment may be effected with EtOH , ethylene or butylene glycol, glycerol, butanol, $\text{Zn}(\text{OH})_2$, alkalis or alk. earths and if desired the fatty acids may in part be esterified and in part converted into salts. Cf. C. A. 23, 961.

Fractionating crude benzene. SOC. DES ÉTABLISSEMENTS BARBET. Brit. 295,591, Aug. 12, 1927. An arrangement of app. is described by which crude benzene is roughly sepd. into 4 products: benzene, toluene, xylene and solvent naphtha; the first 3 by continuous rectification under atm. pressure and the last by a discontinuous rectification *in vacuo*. Numerous structural details of the app. and details of procedure in its use are described.

Gas and liquid motor fuel from coal in a water-gas apparatus. DANIEL J. YOUNG. U. S. 1,706,686, March 26. Hot gases resulting from the blasting of fuel such as coal in a fuel chamber are passed through a heat-interchange chamber and, after desired temp. differences have been established in different zones of the app. used, fluids including air, steam, combustible gas and finely divided oil are admitted to the app. and subjected to heat treatment and reaction. The liquid and gaseous products are withdrawn and sepd. An app. is described.

Hot purification of distillation gases, etc. COMPAGNIE INTERNATIONALE POUR LA FABRICATION DES ESSENCES ET PETROLES. Brit. 295,272, Aug. 8, 1927. In hot purification of gases such as distn. gases used in the manuf. of liquid fuels in which metals or oxides (such as an oxide of Ni) are formed into sulfides and regenerated (one of 2 series of purifiers being placed alternately out of circuit for regeneration) an addnl. pair of small checking purifiers is arranged to follow the main app., each purifier being alternately placed in and out of circuit at much longer intervals and contg. metals such as Cu or oxides which form sulfides stable at the operative temp. of about 250° . Regeneration of the material in the main purifiers is effected in 3 stages. Numerous structural and operative details are described.

Reducing gases. AKTIESELSKAPET NORSK STAAL (ELEKTRISK-GAS-REDUKTION). Ger. 466,859, Dec. 20, 1927; Fr. 646,155, Dec. 24, 1927. Gases contg. CO_2 and steam are heated to about 1400° in an elec. arc and led through a layer of glowing carboniferous material. The heat so supplied not only permits the endothermic production of CO and H , but also melts the slag from the glowing material for tapping off. The carboniferous material may be in the same chamber as the arc.

Desulfurizing gases. FIRMA CARL STILL. Ger. 471,380, Sept. 14, 1927. The desulfurization of gases with an alk. suspension of Fe-O compds. is improved by using Fe-O compds. contg. at least 2% Mn, or by addn. of Mn to the suspension. Cf. C. A. 23, 2023.

Drying fuel gases. C. COOPER, D. M. HENSHAW and W. C. HOLMES & Co., Ltd. Brit. 295,411, April 7, 1927. In drying gases such as "town gas" with liquid absorbents, the rate of withdrawal of the liquid from the drying app. and its rate of return to the app. are maintained substantially constant during a complete sequence of diurnal or other cycle of variations in production and consumption so that the average concn. of the liquid and moisture content of the gas remain substantially constant. In case moisture deposits in the mains during a part of the cycle period, it is evapd. during another part of the cycle so that accumulation is avoided.

Treating coal gas, etc. C. OTTO & Co., G. M. B. H. Ger. 471,332, Aug. 10, 1926. In washing coal distn. gases prior to passing them through a tar separator and a saturator, the loss of washing liquid by evapn. is made good by using the condensate from a cooler arranged in advance of the tar separator.

Water gas. GAS UND TEER GES. Brit. 296,004, Aug. 24, 1927. In continuous generation of water gas from powdered fuel, steam and powdered fuel in a current of water gas are supplied through inlets near the bottom of a heated chamber and the water gas generated and the fuel residue passed through an outlet near the top of the chamber into a dust separator from which part of the water gas is discharged; the remainder of the water gas passes from the dust separator into a chamber where it is burnt with air, and the direction of materials through the app. is periodically reversed so that the chambers serve as heat regenerators. Various structural details are described.

Water-gas plant. FRANKFURTER GAS GES. and F. REICHARD. Brit. 295,900, Jan. 31, 1928. The blast gases are used to heat a steam boiler which is also heated by a continuous auxiliary fuel supply which is throttled during the blasting period.

Regenerative apparatus for continuous production of water gas. J. PINTSCH A.-G. Brit. 295,717, Aug. 19, 1927. Hot gas and steam enter a central tube of the app. and this tube is externally heated and surrounded by a regenerator. Powdered fuel is supplied to the central top portion of the tube. Various other structural details are described.

Hearth of gas-producer. LE CHAUFFAGE INDUSTRIEL. Fr. 646,581, Dec. 30, 1927.

Pyrogenic decomposition of hydrocarbon materials. I. G. FARBENIND. A. G. Brit. 296,034, Feb. 22, 1927. Coal, tars, mineral oils, bitumens, coal extn. products, coal hydrogenation products, oil shists or the like are atomized and heated with steam to effect decompn. with production of gases rich in olefins which are then heated, with or without pressure, and with or without catalysts, to produce liquid hydrocarbons of low b. p. which may in part be aromatic. A very large number of details are given as to catalysts which may be used and other features and modifications of the process.

Tar distillation. THE BARRETT CO. Fr. 646,858, Dec. 16, 1927. See Brit. 286,278 (C. A. 23, 266).

Distilling tar. S. P. MILLER (to Barrett Co.). Brit. 295,687, Aug. 17, 1927. A composite pitch compn. is obtained by subjecting tar to distn. by direct contact with hot coal gases to produce a high m. p. hard pitch residue which while still hot is blended with tar to form a homogeneous mixt. suitable for use as a liquid fuel, or creosoting or roofing compn. An arrangement of app. is described, in which pitches having a m. p. of about 150-200° may be obtained by the described procedure. Cf. C. A. 23, 961.

Distilling tar, oils, etc. W. RUNGE (to International Combustion Engineering Corp.). Brit. 295,945, Sept. 21, 1926. An arrangement of app. is described in which the material is heated by hot gases such as flue gases (by indirect contact) and these gases are subsequently used to condense vapors produced in the distn.

Distilling tars, oils, etc. W. RUNGE (to International Combustion Engineering Corp.). Brit. 295,946, Sept. 21, 1926. The hot gases produced in the distn. are freed from contained vapors by condensation and are then reheated and again introduced into the distn. chamber. An arrangement of app. is described which may include a still with a rotating casing as described in Brit. 277,952 (C. A. 22, 2497).

Oven for melting tar, asphalt, etc. MAX SCHULZE. Ger. 471,378, May 31, 1925.

Coking. GRASCHER SULZER A.-G. Swiss 127,684, Mar. 26, 1927. Addn. to Swiss 122,951. A dry cooling plant for glowing coke has a chamber near the ground with double walls forming a jacket into which cooling medium can flow from a reservoir.

Regenerative coking oven. HINDELMANN, KOKSOFENBAU, G. M. B. H. Ger. 471,190, Apr. 2, 1927. Addn. to 469,480.

Coking retort oven and regenerator construction. JOSEPH BECKER (to Koppers Co.). U. S. 1,706,476, March 26.

Coking retort oven and regenerator construction. JOSEPH VAN ACKEREN (to Koppers Co.). U. S. 1,705,841, March 19.

Coke oven wall construction. F. TOTZEK. Brit. 295,906, Feb. 16, 1928.

Semi-coke. KOKS- UND HALBKOKS-BRIKETTIERUNGS. G. M. B. H. (Ludwig Weber, inventor). Ger. 471,358, Oct. 15, 1926. Semi-coke is prepd. by low-temp. distn. of briquets prepd. from bituminous coal having more than 16% of volatile constituents and a water-sol. org. or inorg. binder, e. g., sulfite cellulose lye.

22—PETROLEUM, LUBRICANTS, ASPHALT AND WOOD PRODUCTS

W. F. FARAGHER

Apparatus and method for the separation, identification and determination of the chemical constituents of petroleum. EDW. WASHBURN, JOHANNES H. BRUUN AND MILDRED M. HICKS. *Bur. Standards J. Research* 2, 467-88(1929).—The heavier fractions of an Oklahoma petroleum were used, beginning with the gas-oil fraction. Distn. was conducted by holding the oil in the still at a const. temp., below cracking, and forcing dry pure CO₂ through it in streams of fine bubbles. The rectifying column of 20 plates had a sep. heating coil for each plate, so that complete control was possible. A temp gradient of 70° between bottom and top plate was maintained. The oil was distd. to 350° in 9 fractions. From some tests made as to the influence of an inert gas upon the amt. of cracking in the oil, estd. from the I no., it was clear that as between H, N and CO₂ there was little difference. When heating with CO₂ to 370° was continued for 20 hrs., the increase in I no. was less than 1/3 of that produced in contact with air by boiling for 20 hrs. under return condenser. For further fractionation of the fractions obtained as above, a series of all-glass vacuum stills was provided. Heating was by a bath of nickel shot electrically heated. Mol. stills were necessary for distg. the higher-melting paraffin waxes. Such stills are characterized by very high vacuum, large and clean vaporizing surface, short distance from vaporizing surface to condenser and sufficient temp. difference between vaporizing and condensing surface. Several forms of mol. still are shown. Where there is no recondensation on the evapg. surface, the rate of distn. of a given "molecular species" may be calcd. from Langmuir's formula, $n = pS\sqrt{1/2\pi MRT}$, in which n = no. of moles distg. per sec., p is vapor pressure at the evapg. surface at temp. T° K., S is the effective surface, M the mol. wt. and R the gas const. The temp. necessary for condensation may also be calcd.; or, the difference between vaporizing-surface and condenser-surface temp. may be taken to be not less than 60°. Crystn. and the equil. melting point method were applied to fractionation very successfully. No petroleum fraction was found which could not be crystd. readily. A metal-to-glass or glass-to-glass combustion app. gave accurate results and made it possible with the aid of a mol. wt. detn. to det. the empirical formula of any hydrocarbon up to C₁₀₀. EMMA E. CRANDAL

Petroleum industry in Japan. KEISABURO HASHIMOTO. *J. Fuel Soc. (Japan)* 8, 191-200(1929).—A review. F. I. NAKAMURA

Petroleum products for lighting and heating. L. SINGER. *Petroleum Z.* 24, 1125-9(1928).—A review of the literature and patents during 1927 relative to lighting and fuels including oil gas, carbureted water gas, air gas, etc., containing 71 references. M. B. HART

The development of the cholesterol question in petroleum chemistry. M. A. RAKUZIN. *Petroleum Z.* 24, 898-902(1928).—The literature on cholesterol and its decompn. products in petroleum since 1906 is reviewed and 29 references are given. M. B. HART

Animal and vegetable fats as mother substances of inactive constituents of petroleum. M. A. RAKUZIN. *Petroleum Z.* 24, 1519-20(1928).—Palmitic acid and stearic acid have been treated with AlCl₃ to produce in the former about 60% of a cryst. product which on purifying has been identified as a mixt. of paraffins having a mol. wt. of about 412 (Rast method) corresponding approx. to the compd. C₁₆H₃₄ and from the latter crystals having a mol. wt. of 511 corresponding approx. to the formula C₂₀H₄₂. M. B. HART

Bituminous shales and their relation to petroleum. A. F. V. STAHL. *Petroleum Z.* 24, 1171-2(1928).—Decayed sludge or sapropel is considered the source of petroleum,

the carbonaceous plant residue serving for the formation of bituminous shales whose oil content is too small to produce workable oil reservoirs. M. B. HART

Electrical dehydration of oil in the Comodoro Rivadavia Field Argentine. L. D. WYANT. *Natl. Petroleum News* 20, No. 42, 119-20, 124(1928).—Oil from the Comodoro Rivadavia oil field in the Argentine forms permanent emulsions which can be dehydrated by pipe stills as long as the water content is below 10%. Cottrell high-voltage elec. units operating at 80° with heavy oil and 65-70° for mixed oils have been used with success to dehydrate oils of higher water content. M. B. HART

Determination of halogens in the salt water of the Rumanian oil fields. P. PETRESCU. *Petroleum Z.* 24, 945-6(1928).—See C. A. 22, 3981. M. B. HART

Making oil-testing methods uniform. H. SCHLÖTER. *Petroleum Z.* 24, 699-701(1928).—Cf. C. A. 22, 2283, 2658. M. B. HART

Forty below zero chilling produces oil viscous when hot, fluid when cold. P. TRUESDELL. *Natl. Petroleum News* 21, No. 4, 27-8(1929).—A mixt. of Ranger and Burbank crude oils has been fire and steam distd. to a long residuum having a flash of 445° F., max. still temp. of 650° F., which was acid treated, neutralized, blended with naphtha and chilled to -10° F. as in the usual Sharples practice and then chilled by direct ammonia expansion to -40° F. and centrifuged in a Sharples machine. The chilled oil was split into 83.5% dewaxed oil and 16.5% petrolatum. The dewaxed oil was reduced by distn. and filtered to a 6 1/2 N. P. A. color to give an oil having the following properties: gravity 24.2, flash 445° F., fire 510° F., pour 0, cloud none at -8° F. The long residuum was also divided into overhead neutral and residual bright stock. M. B. HART

Forty below zero chilling produces oil viscous when hot, fluid when cold. M. B. MILLER. *Natl. Petroleum News* 21, No. 5, 69-70, 72(1929).—The ammonia absorption and direct expansion system used in cooling overhead oil or bright stocks, diluted with naphtha to -40° F., are described. M. B. HART

Oil and gas from slack coal extracted by Hayes process. J. BALPH, Coal Carbonization Co., AND M. J. McQUADE, Ben Franklin Coal Co. *Oil & Gas J.* 27, No. 39, 156, 167(1929).—The Hayes process for producing domestic fuel from slack coal is described. M. B. HART

Making bituminous coal from oil. WALTER F. RITTMAN. Carnegie Inst. Technology. *Oil & Gas J.* 27, No. 28, 54(1928).—See C. A. 23, 695. M. B. HART

Mechanical sniffer tells explosion hazard of oil-gas mixtures. H. H. HALL, S. O. Co. of California. *Natl. Petroleum News* 20, No. 52, 60-1(1928).—An electric detector comprising an elec. wheatstone bridge circuit having an electrically heated Pt filament in the circuit is used for the detection of explosive mixts. in tanks, cargo space on ships, etc. Samples of the gas to be tested are drawn over the Pt wire and the tendency to explode is read directly on an indicator dial. The Standard Oil Co. of California through Messrs. Williams and Johnson of Palo Alto, California, offer the app. to those interested. M. B. HART

Elimination of mosquito offers broad market for special oils. J. M. GINGRICH. *Oil & Gas J.* 27, No. 32, 150, 204(1928).—A suitable oil for mosquito extermination must kill rapidly, spread well and be long lasting. The specifications of such an oil are given: gravity, 30-34° B₆₀; flash, 130-140° F.; distn. range 10% over at 300° F., 40% over at 400-550° F., 50% over at 550-750° F.; viscosity 50 Saybolt at 100° F. Light fuel oil with proper blending to give the desired boiling range may serve as a basis for such an oil. The toxicity of 10 oil samples to salt marsh larvae is compared. M. B. HART

Determination of the properties of oils used in the absorption of gasoline from natural gas. L. D. McLOUTH. Pan American Petroleum Co. *Petroleum World (Los Angeles)* 13, No. 8, 102-6, 108(1928).—A series of expts. on absorption oils shows that oils having a distn. range of about 100° F. between 280° and 450° F. absorb more effectively as their gravities increase between 32 and 80 A. P. I. providing the initial b. p. is not less than 280° F. Absorption varies inversely with viscosity in this gravity range. Lean oil should be stripped as far as possible to insure absorption of volatile components. Absorption decreases with temp. increase between 40 and 100° and varies directly with abs. pressure, reaching a satn. point. Oil from a particular field does not appear to have a special relation to gas from that field. M. B. HART

Sulfur crude oils fast losing bad reputation. GEORGE RAIN. *Refiner & Gasoline Mfr.* 7, No. 8, 59, 62(1928).—Although the handling of high-S crude oils is attended by corrosion, by the use of chemicals for neutralization, the corrosion can be checked to a large extent and at very little addl. cost. The refining is completed by the usual methods with no redistn. of gasoline. M. B. HART

West Texas crude refining problems. H. H. HEWERTSON. *Beacon Oil Co. Oil & Gas J.* 27, No. 29, 118, 181, 182(1928).—The customary acid-doctor-rerun treatment of West Texas distillates does not remove the S. The use of large quantities of acid, e. g., 30 lbs. 66° acid per bbl., and rerunning reduced the S content of cracked distillates from 0.38 to 0.03% in the unsweetened gasoline. A preliminary treatment with doctor or hypochlorite tends to reduce the S but addnl. acid achieves the same result. Glacial acetic acid and sirupy phosphoric acid appear inert. Concd. HNO_3 apparently oxidizes and nitrates certain compds.; concd. halogen acids seem to form halides or addn. compds. with unsatd. compds. Hypochlorite does not remove S; vapor-phase clay treatment does not reduce the S content appreciably. Metallic chlorides sweeten but do not remove S; HgCl_2 forms compds. which cannot be washed out. Satd. solns. of mercuric salts, particularly the acetate, with H_2SO_4 reduce the S by 0.04 to 0.05% below that obtainable with acid alone. M. B. HART

The chemical composition of Rumanian crude oils according to source and geological occurrence. N. DANAILA AND V. STOENESCU. *Petroleum Z.* 24, 1303-9(1928).—Crude oil samples collected at the well have been fractionated to give fractions boiling below 145° and 145-300°, the first fraction being refractionated to give fractions 65-95°, 95-115°, 115-145°. Each fraction was dried over CaCl_2 for a day and distd. over metallic Na. Each fraction was analyzed to give the volatile content of aromatic hydrocarbons, olefins, hexahydroaromatics and satd. compds. Results obtained indicate that there is no relationship between chem. compn. of the oil and the geological era. M. B. HART

The low-temperature carbonization of shales. Present condition of the problem in different countries. DAVID BROWNLIE. *Chaleur et ind.* 9, 234-42(1928); cf. C. A. 23, 270.—Because of the development of oil fields, the exploitation of shales is having little success. Australia and Tasmania have worked at the problem for many years. The Pumphierston, Fell, Black and Bronder processes have been tried there but no com. solution has been found. Canada has large shale deposits which are under investigation on a large scale. Esthonia is one of the scientific leaders in shale exploitation. Importation of fuel is forbidden and the rich shales give 270-315 l. crude oil/ton; 750,000 tons of shale is thus utilized per yr. The Pintsch plant consists of very large vertical cylindrical retorts of sheet steel, internally heated by steam and air introduced at the base. As the charge descends, its temp. increases and vapors are evolved. B. says that France is not seriously studying the question of shale utilization. For modern working, very large retorts are required, allowing large charges of shale to be treated. The shale industry has made little progress in Germany, and in Gt. Britain, it is not prospering. The reasons assigned are: (1) Poorer shales are available; (2) the Pumphierston retort is imperfect; (3) the government is paying little attention to the industry. A brief description of the Crozier and Lamplough retorts is given. In Japanese Manchuria, there are vast deposits of shale from which Japan is endeavoring to obtain a fuel suitable for the Navy. The U. S. possesses very rich deposits of shale and in spite of the exploitation of petroleum, 75 processes for treating shale have been tried. Some information is given about the following processes: American Hydrocarbon Co., Brown, Cutlin, Chew, Crouse, Day-Heller, Debrey, Lamb and others. South Africa, Poland and Brazil are also giving attention to the exploitation of their shale deposits. S. L. B. ETHERTON

The use of bleaching earths in the mineral oil industry. O. ECKART. *Petroleum Z.* 24, 1441-3(1928).—Several references are cited in an attempt to bring the article by Typke (C. A. 22, 267) to date. M. B. HART

Improving mineral oil refining. F. SCHWARZ. *Petroleum Z.* 24, 803-10(1928).—In the pptn. method oils such as transformer oils are refined by alkali treatment of oils contg. naphthenic acids or by alkali treat of oils to which naphthenic acids have been added. The color-forming impurities in the oil are carried out by the colloidal action of soaps formed and removed by centrifugation. Oils so refined compare very favorably with oils refined by treatment with H_2SO_4 or acid and alkali treatment following the pptn. method. The use of acid treatment followed by the pptn. method is suitable for used oils. M. B. HART

A source of error in the determination of sulfur in mineral oils. K. FISCHER AND W. HESS. *Erdöl u. Teer B.* 83-4(1929).—An appreciable portion of the S appears as SO_2 in the combustion products, especially in the Hessinger app. in which the gases pass relatively slowly through a considerable length of tube at a temp. favorable to SO_2 formation. As a result of fog formation, it escapes absorption in the H_2O_2 soln. The fog can be caught completely by passing the gases leaving the absorber through a

moistened No. 4 Schott glass filter, or almost completely through 2 No. 3 filters in series. The latter permit a more rapid flow. F. S. GRANGER

The modifications of paraffin in various mineral oils. EWALD PYHÄLÄ. *Petroleum Z.* 24, 902-6(1928).—A study of the paraffin content of various Russian crude oils has shown that crude oil contains primary paraffin hydrocarbons with or without secondary mineral wax or ozocerite. The presence of dissolved ozocerite in paraffin contg. crude oils has been shown experimentally by the method of M. M. Tichwinsky, whereby the ozocerite is removed from emulsified oil by filtration. The formation of ozocerite deposits in rock fissures is due to the sedimentation of emulsified oil carrying flocculated ozocerite in suspension. The possible inorg. origin of ozocerite is pointed out. M. B. HART

Extinguishing burning mineral oils. M. A. RAKUZIN. *Petroleum Z.* 24, 1091-2 (1928).—Oil fires are readily extinguished by the action of 6-8% Na_2CO_3 and K_2CO_3 solns. whereas $(\text{NH}_4)_2\text{CO}_3$, NaCl , CaCl_2 , BaCl_2 , $\text{Fe}_2(\text{SO}_4)_3$, alum, $\text{Pb}(\text{OAc})_2$ and dil. and concd. NH_4OH solns. have no effect. The effect of the use of soda soln. on kerosene is to increase the sp. gr. and flash, and produce a brownish color which may be removed with H_2SO_4 . It is not improbable that Na salts of the naphthenic acids may exert fire-extinguishing effect. M. B. HART

Breakdown of insulating mineral oils. T. AIKAWA. *Electrotech. Lab. Tokyo, Japan, Circ. No. 46*, 47 pp.(1927); *Science Abstracts* 31B, 301. A review of the dielectric strength of mineral oils affected by moisture, temp. and impurities of low insulating property, with the results of many breakdown tests made on several com. transformer and switch oils. The electrodes used in the breakdown test were two brass balls of 12.5 mm. in diam. and 2.5 mm. apart. The phenomena of breakdown were observed by means of a telescope, oscillograph and high-speed motion-picture camera. The av. breakdown voltage (500-1000 tests) of each sample was above 25 kv., but the breakdown voltage sometimes dropped to 10 or 12 kv. in consequence of the presence of fibrous material, dust, etc. H. C.

New process for the filtration of insulating oils. F. SOCCART. *Rev. gén. élec.* 23, 749-52(1928); *Science Abstracts* 31B, 348. Sheets of specially prepd. collodion, which may be used in an ordinary filter press, are made by an impregnating process on a cotton or silk support, the peculiarity of the process being that it leaves the sheet perforated with closely spaced, minute holes of the order of millionths of a mm. in diameter. By "ultra-filtration" with these membranes colloidal C can be removed without choking the pores of the membrane, which can be surface cleaned and used again. Considerable improvement, both as regards the dielectric strength and the index of emulsification, is claimed for oil treated in this way. A filter press has been re-equipped with membranes 1 sq. m. in area, and is capable of cleaning 20 kg. of oil (presumably per hr.) at one pass with a pressure of 1 kg. per sq. cm. H. L. D.

Improving fractionation for cracking processes. D. B. KEYES. *Chem. Met. Eng.* 36, 78; *Natl. Petroleum News* 21, No. 11, 78-9(1929). Two methods are proposed for obtaining better fractionation of cracked products. Both methods consist essentially in passing the vapors to be fractionated through a heating coil in the lower part of the bubble tower before discharging the vapors into the tower at an intermediate point. The top of the tower is cooled by means of a coil through which fresh feed stock is passed. D. F. BROWN

Fractionation at low temperature. O. G. OBERFELL AND R. C. ALDEN. *Phillips Petroleum Co. (Oil & Gas J.)* 27, No. 22, 142, 364, 366, 368, 370, 372(1928). The modified Shepherd-Porter app. as developed in the lab. of the Phillips Petroleum Co. is described, together with the method of operation for natural gasoline, motor fuel and gases. M. B. HART

High-pressure fractionation method. G. G. OBERFELL, L. S. GREGORY AND T. W. LUCATEKI. *Oil & Gas J.* 27, No. 22, 251, 281(1928).—An app. for the fractionation of natural gasoline consists of a 5 gallon capacity still with an ordinary rectifying column, a dephlegmator, condenser, receiver and cooler. The rectifying column is filled with small pieces of metallic strips having deep corrugations. The set up and use of the app. are described. M. B. HART

in the vapor phase. S. J. M. AULD. *Petroleum Times* 21, 29-100, 186-60(1929).—The Hall, Rittman and Ramage processes have been of particular interest in the development of vapor-phase cracking-processes. The Ramage process under the name of the Gyro process is again of interest as a means of producing gasoline having high compression and anti-knock value. The process as now carried out is described and yields are given. M. B. HART

Tests show sulfur content of different fractions. H. L. KAUFFMAN. *Refiner*

Natural Gasoline Mfr. 7, No. 8, 73-4(1928).—The S content is given of gasoline, kerosene, gas, oil, wax distillate, fractions and bottoms of Lander, Wyo., crude oils having an original S content of 3.16% (bomb method) and Lost Soldier, Wyo., crude oils having an original S content of 0.23%.

M. B. HART

Formation of acetic acid in heat and pressure cracking. F. W. HALL AND R. DE M. TAVEAU. *Oil & Gas J.* 27, No. 29, 110, 286(1928).—The presence and source of fatty acids in cracking crudes have been proved by sapon. of gas oils and washing out the acids from the soap soln. Naphthenic acids were heated at 815° F. under a pressure of 200 lbs. per sq. in. in an exptl. still having a reflux condenser and after the Fe was removed from an aq. ext. of the material remaining in the still, the soln. was esterified with C_2H_5OH with the subsequent production of ethyl acetate and other esters. This indicates that fatty acids may be formed from naphthenic acids in cracking. Recent work with acid water from virgin gas oils in which the acids have been sepd. by the methods used for recovery of acetic acid from pyroligneous liquor shows the acetic acid content of the acid water to be about 1.54%. The analysis of a sample of volatile acids from the acid is given.

M. B. HART

Kvitko cracking still. A. M. TREGUBOV. *Proc. of the First All-Russian Scientific Tech. Mining Congress 1926* 5, 42-53(1928).—Mazout after preheating is cracked at 420-430° and 5 atm. pressure in a shell still 7.1 m. long and 0.885 m. in diam. which has been tested with cold solar oil at 25 atm. The heating is discontinued after 25% has distd. over and the cracking continued by radiant heat from the furnace until 50-60% of the original charge is left in the still. Fresh stock may be added during the operation if required, preheating it by contact with the hot vapors in the vapor-line. Three air-cooled dephlegmators are connected to the still, which may be used separately if desired. Each contains 19 tubes. The total cooling surface of the 3 dephlegmators is 16 sq. m. A pressure-reducing valve is placed after the dephlegmator, connecting with a large condenser which can handle 800 kg. of oil per hr. Two reducing valves are attached to the condenser, one discharging the condensate to the storage tank, the other discharging the gas through a scrubber, where it passes to the gas holder. A small cooling coil is attached to the dephlegmator to cool the condensed oil. Condensers are also provided on the safety valves and on the bottoms-discharge pipe on the still.

A. A. BOEHLINGK

Pure Oil Co. making further installations of Gyro cracking process. G. REID. *Refiner Natural Gasoline Mfr.* 8, No. 1, 68-70(1929). The Gyro process is being installed by the Pure Oil Co. at its Smith's Bluff, Texas, and Heath, Ohio plants. The process consists in passing vapors of any oil through a tube still and evaporator from which steam and oil vapors pass through a separator and into a catalyst chamber. The mixt. is heated to 1100° F. The catalyst consists of a cylindrical core of concrete impregnated with iron oxide. Vapors from the converter are passed through a tar leg, fractionating tower, vapor-phase treating tower, a second fractionating tower and condenser.

M. B. HART

The Lurgi retorting process. F. A. VETKEN AND O. HUBMANN. *Petroleum Z.* 24, 977-82(1928).—The Lurgi low-temp. process which operates on lignite, cannel coal, shales, etc., consists in passing the charge through drying, distn. and cooling zones in a vertical retort where it is heated by waste gases passing upwardly through the retort to which combustion gases are added as desired. Yields when running with lignite and brown coal are given.

M. B. HART

Kiton process. OTTO BAUMGARTNER. *Petroleum Z.* 24, 1617-8(1928).—The use of a special tar-bitumen emulsion "Kiton" is described.

M. B. HART

A simple graphical analysis found better than analytical methods for distillation problems. E. G. RAGATZ. *Petroleum World* (Los Angeles) 13, No. 12, 102-3, 115 (1928); *Oil & Gas J.* 27, No. 33, 140-1(1929).—The graphical method for absorption and distn. problems is developed with concrete examples.

M. B. HART

Progress in combating the corrosion of pressure stills. W. F. FARAGHER. *Am. Petroleum Inst., Bull.* 10, No. 2, 102-6(1928); *Petroleum Times* 21, No. 522, 43-4(1929).—Chromium steel tubes containing 17 to 20% of chromium resist the corrosive action of high-sulfur oils, but are too brittle for use. The alloys are said to be free from that defect if the chromium is limited to 14% or under. Tubes containing 5% of chromium last 3 to 4 times as long as plain steel tubes and cost 2½ times as much. Chrome iron tubes are resistant to corrosion and may be used for vapor-phase coils where their brittleness is not a drawback. Coke deposits in them more slowly than in steel tubes. Calorizing prevents corrosion by furnace gases and by hot corrosive cracked oils if the coating is not ruptured. Chromium plating gives very good protection in chambers, but in tubes the plating is so far too easily ruptured in cleaning. The use of soda or

lime as neutralizer is apparently not increasing. Lime is preferred because it has less tendency than soda to clog up the tubes. The Roxana Petroleum Corporation applies a coating of portland cement, sand, and pulverized fire brick mixed, to the interior of chambers, with good results. The Universal Oil Products Co. has developed a coating composed of water glass, sand, and furnace cement. In the best of the tests thus far made the coating has adhered well and given complete protection to the surface covered.

EMMA E. CRANDAL

Corrosion. H. F. PERKINS. *Am. Petroleum Inst., Bull.* 10, No. 2, 100-2(1928).—The Refinery Sub-Committee of the A. P. I. General Committee on Corrosion is engaged in collecting records of such tests and observations as are being made in the refineries looking to the reduction of corrosion. With a sufficient mass of such material collected and correlated it will be possible to send out to refiners standardized methods of testing and to equipment manufacturers the information necessary for perfecting their product with reference to its special use.

EMMA E. CRANDAL

Smooth operation of stabilizer by feeding through surge tank. E. R. COX. *Texas Co. Natl. Petroleum News* 21, No. 6, 70, 72(1929).—A discussion of various factors affecting stabilization indicates that the feed is best controlled by combining all streams in a surge tank and feeding the mixt. into the column at one level. The upper limit of column capacity is indicated when a column primes; the most effective head of liquid seems to be 4 to 6 in.

M. B. HART

Converting carbons by catalysis. CARL KRAUCH. I. G. Farbenindustrie. *Oil & Gas J.* 27, No. 39, 156, 158, 160(1929).—The conversion reactions of CH_4 and higher hydrocarbons in the presence of catalysts are discussed. The decompn. of CH_4 to give C_2H_2 and H_2 or C and H_2 is easily shifted and the first reaction is best conducted by heating in an elec. arc. With aliphatic hydrocarbons the C—C linkage is more easily broken than the C—H linkage, but catalysts vary in their attack on the molecule. C chains, are split by V, Mo, W, U and their oxides, while Cu, Ni, S and Se tend to promote dehydrogenation. Fe lowers the cracking temp. and favors dehydrogenation of aromatic and hydroaromatic hydrocarbons, but promotes condensation. AlCl_3 acts as a cracking or polymerizing catalyst. BF_3 and AlCl_3 are well suited for lubricating oil manuf. By oxidizing paraffin, fatty acids are produced. Antiknock compds. such as iron carbonyl, lead tetraethyl, etc., are neg. catalysts. Industrial hydrogenation is conducted with the oil or tar (1) in the form of a spray conducted over the catalyst (2) vaporized and (3) in the liquid phase. General hydrogenating conditions for oil and coal are reviewed.

M. B. HART

Use of catalytic agents in revivifying used filter clay. F. R. LANG, A. P. ANDERSON AND G. H. VON FUCHS. *Oil & Gas J.* 27, No. 29, 114, 258(1928).—Although the use of catalysts in the revivification of used clay at 1000° produces lighter colored clay than samples to which no catalysts were added, in all but two cases, Cd and Al, the decolorizing effect of the clay was impaired. Derivs. of Cu, Fe, or Zn showed the worst effect.

M. B. HART

Naphthalenesulfonic acids. ST. V. PILAT AND E. DAVIDSON. *Petroleum Z.* 24, 1550-61(1928).—Crude naphthalenesulfonic acids have been treated with dil. NaOH followed by repeated extns. with ether, the ether exts. evapd. and dried at 120°. The product so obtained has been studied by the acetone method and found to be a mixt. of monobasic acids. Two series of salts are formed which may be distinguished as α - and β -salts by their soly. in ether. The mol. wt. detn. of the ether-sol. Ba salts corresponds to a compd. having the formula $\text{C}_{10}\text{H}_7\text{SO}_3\text{H}$.

M. B. HART

Propulsive efficiency of air and gas. HARRY H. POWER. *Gypsy Oil Co. Oil & Gas J.* 27, No. 22, 164, 352, 354, 356, 359(1928).—The soly. of N_2 in oil is close to that of air and less than that of natural gas. Whereas increments of dissolved gas lower the abs. viscosity of oil, dissolved N_2 up to a certain crit. point lowers the abs. viscosity to a min. beyond which addnl. dissolved N_2 tends to increase the viscosity of the oil up to a certain satn. pressure (200 lbs.). N_2 is superior to natural gas as a propulsive agent. Up to this pressure the viscosities of the gas-satd. and N-satd. oils are close to each other while the Jamin effect is greater with natural gas.

M. B. HART

Specific gravity of liquefied gas. G. G. ONSFELD, T. W. LEGATSKI AND F. E. FRANK. *Phillips Petroleum Co. Oil & Gas J.* 27, No. 33, 148, 158(1929).—A new gr. bomb for volatile liquids is described giving specifications, calibration and test procedure. Filling densities for liquefied petroleum gases having gravities of 0.500-0.585 are tabulated.

M. B. HART

Determination of evaporation losses. E. C. HUNTZEL AND WILLIAM MENDIES. *Shell Refining Co. Oil & Gas J.* 27, No. 29, 124, 167-8(1928).—The detn. of rates

quantities and qualities of gases available from tankage under various conditions is reported. The data show that exhalation on full tankage is small with insulated roofs and water sprays; breathing is large with partially filled tanks, a water spray effecting greatest reduction; exhalation is major after sunrise, inhalation occurring in the cool of the late afternoon. "Pumping-in breathing" for gasoline and crude oil is about 160% of oil displacement representing an oil loss of 0.27%. Tables are given to show variation of properties of the gas for the range of temp. conditions, effect of temp. of oil and air on the characteristics of breathing from crude and gasoline storage, effect of tank pressure on pressure distillate gas. Possible gasoline recovery available from crude and light oil tankage in a 10,000 bbl. refinery is shown as follows: vol. exhaled gases, 500,000 cu. ft.; gross heat value of exhaled gases, 600,000 B. t. u.; liquid vol. of loss, 126 bbls.; liquid vol. recoverable from treating, 60 bbls. M. B. HART

Comparison of Soviet and American kerosenes. S. NAMETKIN. *Petroleum Z.* 24, 1515-9(1928).—See C. A. 22, 2459. M. B. HART

Flash-point determination in standard flash-point testers. G. MEYERHEIM AND FR. FRANK. Chem. Lab. für Handel u. Industrie, Berlin. *Petroleum Z.* 24, 1235-7 (1928).—See C. A. 22, 3039. M. B. HART

Third annual survey of Tulsa gasolines. W. T. ZIEGENHAIN. *Oil & Gas J.* 27, No. 31, 130-2(1928).—Samples of 19 gasolines representative of gasolines sold in the Southwest and Middle West show little change in motor grade from year to year in the product from any one company, that of different companies varying in volatility. Many regular grades are high in antiknock value as shown by high aromatic content. In premium-grade fuels stress is laid on antiknock value. The volatility of the last 50% is more than that a year ago. Blends are improved by the use of low end point naphtha and stabilized natural gasoline. Comparative tests on samples are tabulated. M. B. HART

Several factors to consider in blending natural gasoline. H. G. STEVENSON. Columbian Gasoline Corp. *Oil & Gas J.* 27, No. 36, 126, 133(1929).—The methods used in cold blending gasolines in tanks and cars are briefly described. M. B. HART

Notes on drip gasoline. ALEXANDER B. MORRIS. *Refiner Natural Gasoline Mfr.* 7, No. 8, 78, 80, 98, 100(1928).—In studying drip formation in natural gas lines, various drips were placed at key locations and the samples obtained daily from each were reported with the following data: air temp., gas temp., gasoline temp., state of weather and Standard Engler distn. of the sample. Results show that for the accumulation at any one drip there is no definite relation between winter and summer accumulations, those near the vacuum discharge making more in the winter, but those on the branch lines less in cold weather. M. B. HART

Distillation of natural gasoline. WALTER J. PODBIELNIAK. *Oil & Gas J.* 27, No. 28, 168, 170, 172, 174, 176(1928).—The phys. chem. principles of distn. are reviewed including vapor-pressure curves and their value, influence of pressure on the sepn. obtainable by vaporization of 2 or more hydrocarbons and application of Raoult's law. M. B. HART

Comparison of gasoline content as determined by charcoal test with that based on analysis. P. W. HILL. General Petroleum Corp. *Petroleum World* (Los Angeles) 14, No. 1, 101, 110-1(1929).—A comparison of the gasoline content of gas as obtained by fractionation and charcoal absorption shows that the charcoal test comes within, roughly, 10% plus or minus of the calcd. value and that the av. deviation is approx. 5%, in favor of the fractionation results. Possible causes of discrepancies are pointed out. M. B. HART

Molecular weight determination of Groznuil gasoline by its latent heat of vaporization and vapor tension. N. I. CHERNOZHUKOV. *Izvestiya Teplolekhn. Inst. (Trans. Thermo-Tech. Inst. (Russia))* No. 4, 1927, 25-7.—Mol. wts of Groznuil gasolines were calcd.

by the following equation worked out by C. Mx $\frac{T_2 T_1 M}{T_1 T_2}$ where T_2 and T_1 are the temps. abs. of the unknown compd. and T_1 and T_2 of the standard compd., which is a chem. homolog and therefore could be any satd. hydrocarbon, as hexane, octane, etc., for the mol. wt. detn. of Groznuil gasoline, composed mostly of paraffins. Logarithms P and T of the standard and the hydrocarbon of unknown mol. wt. are plotted on the axes and lines of identical vapor concns. drawn through these curves according to Hildebrand. The intersections of these lines with the curves of vapor tensions would then correspond to T_1 , T_2 , T_3 , and T_4 . A. A. BOEHLINGEK

Determination of the gasoline
POLZIK. *Izvestiya Teplolekhn. Inst.*

by the _____ method. I. M.
Thermo-Tech. Inst. (Russia)) 1927, No.

4, 14-18; cf. C. A. 22, 4239.—The American method was modified as follows: The bomb for gasoline was not rinsed before the test but immersed, together with the vessel contg. the sample of gasoline, in a water bath until the temp. of the bath was reached, requiring up to 1.5 hrs. It was necessary to check the pressure gage every two weeks. The table gives comparison tests of Krasnodar aviation gasoline. The temp. of gasoline was 5°; the gases were released at 20°. Pressure is given in lbs. per sq. in.

Temp. of heating	1st. expt. with rinsing	2nd. expt. with rinsing	3rd. expt. with rinsing
30°	6.4	6.3	6.5
40°	11.3	11.4	11.4
50°	16.8	16.6	16.7

Tables are given for tests with Krasnodar, Grozny aviation gasoline, first and second grade of Grozny gasoline, second-grade Baku gasoline, "Kalooha" gasoline (used in the manufacture of rubber boots); also for Krasnodar aviation gasoline of 80° final b. p.

A. A. BOEHTLINGER

Extraction of gasoline from gas. G. A. SARKISYANTZ. *Proc. of the First All-Russian Mining Scientific Tech. Mining Congress 1926*, 139-75(1928).—The following processes and installations are described: a casinghead manifold as used by the Surakhmud Division, a portable compressed-gas analyzer, a Westcott gas analyzer modified by S., a combined gas-absorption and compression app. (up to 16 atm.) and Tikhvinskii gasoline-absorption plant, where casinghead gas is used for re-pressuring wells. Some typical cases are discussed, e. g., absorption of gasoline with tetralin and the Burdell method. Various charcoal- and oil-absorption installations are described and yields calculated.

A. A. BOEHTLINGER

Gasoline from casinghead gas in Groznuii. S. KH. KHANBEKOV. *Proc. First All-Russian Scientific Tech. Mining Congress 1926*, 177-91(1928). Four hundred and eighty-two l. of casinghead gas from gusher No. 54-147 in the Solenaya Balka contained 475 cc. (985.5 cc. per cu. m.) of gasoline which was sepd. as follows: 150 cc. was retained by a gas trap and a Wolff bottle after cooling in a Cu coil surrounded by ice; 195 cc. was held by a solar oil absorber, and 50 and 80 cc., resp., by two charcoal absorbers. Of the total of 475 cc. absorbed, 28.2% could not be recovered from the absorbents. The absorbed gasoline contained the following fractions: initial b. p. 28°; 34°, 10 cc.; 37°, 20 cc.; 41°, 30 cc.; 45°, 40 cc.; 50°, 50 cc.; 55°, 60 cc.; 62°, 70 cc.; 75°, 80 cc.; 100°, 90 cc.; 114°, 95 cc. The sp. gr. of the absorbed gasoline was 0.649.

A. A. BOEHTLINGER

Significance of gum in gasoline. V. VOORHIES AND J. O. EISINGER. *Oil Chem. J.* 27, No. 31, 152, 155-6, 159(1928).—The various methods for detg. gum in gasoline are discussed. Various gum tests including steam oven, O, Cu dish, wt. of deposit in the inlet passage, and the wt. of C deposit on cylinder heads have been made on fuels. The results show that gasoline may have a high potential gum content as detd. by the Cu dish test and perform satisfactorily in the engine. The conclusions as to specifications for the gumming characteristics of fuel are that the permissible gum content at the time of use should be stated as well as gum stability. The steam oven test and the O gum test described are the most satisfactory. Results indicate that more than 10 mg. of actual gum per 100 cc. at the time of use may produce a deposit on the inlet passage and on the valves. Potential gum formation as detd. by the O test should be less than 10 mg. per 25 cc.

M. B. HART

Indian Refining Co. treats cracked gasoline before storing. GEORGE REID. *Refiner Natural Gasoline Mfr.* 8, No. 1, 60-2(1929).—The continuous treating plant and process for cracked gasoline is described.

M. B. HART

Preheaters at Okmulgee plant remove all gasoline fractions. GEORGE REID. *Refiner Natural Gasoline Mfr.* 8, No. 1, 57-9(1929).—At the Barnsdall Refineries, Inc., Okmulgee, Okla., plant crude oil is preheated by interchange in 6 interchangers with hot vapors and residuum and flashed into a chamber at the top of the first bubble tower. Gasoline vapors from the flashing section pass downwardly through two 6 in. down spouts into the bubble tower at about the third tray. The combined gasoline and kerosene vapors are removed through a reflux condenser section to the seventh tray of the second tower. The second bubble tower has a reboiler section at the bottom. Gasoline reflux is returned to the top of the second tower.

M. B. HART

The Valenta reaction in relation to its use with gasolines and gasoline-benzene mixtures. R. WELLER. *Petroleum Z.* 24, 706-73(1928).—The dimethylsulfate number has been shown to have no value as a means of judging the aromatic content of gasoline.

M. B. HART

Carbon monoxide from automobiles using ethyl gas. W. P. YANT AND L. B. BERGER. *Bur. Mines, Repts. of Investigations* No. 2908, 8 pp. (1929).—An investigation was made to det. whether there is any significant difference in the CO content of the exhaust gas of an internal-combustion engine when "ethyl fluid" (contg. PbEt₄) is substituted for straight gasoline. The equipment and the method of conducting the tests are outlined and results tabulated. Three series of tests were conducted. In one, with fixed adjustments and under prescribed conditions, no change was evident in the content of CO in the exhaust gas either when detonation was distinct or when inaudible. If the spark was retarded to decrease detonation during operation on straight gasoline, the amount of CO per h. p.-hr. was 5-7% less for ethyl gasoline than for straight gasoline.

W. H. BOYNTON

The electrical conductivity of certain organic substances as related to knocking. A. MORA AGÜES. *Anales soc. españ. fis. quim. (tecnica)* 26, 155-62 (1928).—The influence of elec. cond. in the liquid phase of motor fuels is shown. Cond. was calcd. from the time of discharge of an electrometer. Results agree well with the bouncing-pin app. of Midgley and Boyd. Two diagrams show variations of cond. on increasing the xylene and xylidene contents of a standard gasoline. Every antiknock substance has a high cond. in the liquid phase.

E. M. SYMMES

Economic phase of antiknock fuels. L. C. LIGHTY. *Yale Univ. Oil & Gas J.* 27, No. 36, 32, 142 4 (1929).—An analysis of the economic value of the use of high-compression fuel from the viewpoints of fuel cost, C-removal cost, and engine performance leads to the following conclusions: (1) the C-removal saving resulting from the use of doped fuel is highest for the lowest compression ratio; (2) fuel saving varies with compression ratio and cost of fuel for any given ratio; (3) for a given dope, C-removal saving varies only with the cost of removing the C; (4) with low fuel costs no saving seems to result from the use of doped fuels with the present compression ratios; (5) with higher fuel costs the net saving increases; (6) whether the use of doped fuel is economical at a compression ratio of 5 to 1 depends upon the C-removal saving; (7) under actual operating conditions, at lower speeds, the fuel economy resulting from higher compression with the existing gear ratio will be less than expected from a full load analysis; (8) gear reduction when decreasing compression results in fuel economy. It is pointed out that the use of high compression should be considered desirable as a means of conserving our national resources, even though the net saving to the consumer is questionable.

M. B. HART

The determination of paraffin hydrocarbons in commercial benzenes and motor fuels. R. HEILINGÖTTER. *Chem.-Ztg.* 53, 79 (1929); cf. *C. A.* 22, 4781.—A 25-cc. sample of material is shaken with 50 cc. of fuming H₂SO₄ contg. 4-5% of SO₃, in a reaction vessel provided with a cooling coil. When the temp. rises to 40-50°, the vessel is cooled. The process is repeated until no temp. increase is noted; the liquid is transferred to an attached measuring tube and the vol. of unaltered hydrocarbon detd. This residue is examd. with a Zeiss refractometer after washing with H₂O; if it reads more than 25 scale divisions, either incomplete sulfonation or the presence of tetralin is indicated. The residue must then be tested by the method of Formanek (*C. A.* 22, 2826).

W. C. ERAUGH

Automotive fuels and lubricants. B. E. SIBLEY. *Continental Oil Co. Oil & Gas J.* 27, No. 28, 148-9 (1928).—The present attitude of engineers toward compression ratio, volatility, initial b. p. and lubricants is expressed.

M. B. HART

Edeleanu sulfur dioxide process used in treating lubricating oils. RUDOLPH PLANK. *Natl. Petroleum News* 20, No. 46, 63-6, 68, 70-1; *Z. Ver. deut. Ing.* 72, 1613-18 (1928).—The Edeleanu process for the treatment of kerosene at low temps. (about 14° F.) with liquid SO₂ is applied to lubricating oils whereby it is claimed that resinous and asphaltic products as well as aromatics are extd. and S compds. are dissolved so that the refined oil contains only about 10% of the S present in the original distillate. Crude distillate and SO₂ at 14° F. are mixed and the refined oil is sepd. and heated with 15% SO₂ to 50° F. by indirect heat exchange with unrefined distillate and passed to the evaporator where the SO₂ is largely removed by exhaust steam. The ext. soln. is heated to about 54° F., the SO₂ driven off being returned to the condenser. The evaporator pressure is between 40 and 65 lbs. In actual practice a series of evaporators is used, the first stage operating at condenser pressure, the second at atm. pressure, the third under vacuum.

M. B. HART

Refining Pennsylvania lubricants. C. O. WILLSON. *Oil & Gas J.* 27, No. 24, 140, 142, 144 (1928).—The newer methods in use by lubricating oil refiners include the use of continuous instead of batch operation, contact filtration and centrifugal sepn. in the manuf. of bright stocks. Pipe stills are used for skimming, the topped crude

being run in a battery of shell stills. Vacuum distn. of lubricating oil stocks is being perfected on the following lines: topped crude is charged to a pipe still unit and discharged into a vaporizer of a large bubble tower unit. M. B. HART

Vaporization of lubricating fractions. W. A. PETERS, JR. AND J. V. JIRASEK. E. B. Badger & Sons Co. *Oil & Gas J.* 27, No. 29, 149, 262(1928).—A comparison of various methods of vaporization for lubricating fractions shows that there is no essential difference between vacuum and atm. or single- and double-stage operation. All available data seem to prove that there is a limit of temp. and time of heating which cannot be exceeded without changing the oil and that, if this limit is not exceeded, the products will be the same regardless of the method used. Vacuum units result in fuel economy although steam distn. will produce the same results. M. B. HART

Towers in series fractionate low cold-test lubricating distillate. GEORGE REID. *Refiner Natural Gasoline Mfr.* 7, No. 12, 57-9, 74(1928).—At the McMillan Petroleum Products Co.'s El Dorado refinery preheated Smackover crude oil is fed into a tube still under 40 lbs. pressure, operating at 600° F. Foxboro type automatic flow controllers are used on the crude charging lines. The heated oil is passed through a stripper tower from which the asphalt residue (50-52%) is charged to an asphalt plant, where it is blown with air to 140-160 penetration and 110° F. m. p. The fractionating app. is of the Boner and Sheldon type, side streams being removed when desired and steam-stripped in stripper towers, the vapors being returned to the main tower. Naphtha is fractionated in a third tower. The tower pressures vary, 25-30 lbs. being the outlet pressure of the tube still, 14-15 lbs. in the stripper columns, about 12 lbs. in the fractionating tower and 10-11 in the final naphtha tower. The naphtha is not treated before sale, liquid NH_4OH being introduced near the bottom of the tower to keep it slightly alk. The yields from Smackover crude oil are 10-12% naphtha, having the following properties: initial b. p. 160-170° F., end point 440-450° F., gravity 45-46 A. P. I.; gas oil 28-30% having a gravity of 26-27 A. P. I., flash 230-240° F., cold test below -50° F., lubricating oil distillate 10-12% having a viscosity of 250-260 at 100° F., flash 380-400° F., cold test 0 to -10° F. M. B. HART

Cylinder oils for steam engines. N. I. CHERNOZHUKOV. *Izvestiya Tekhnich. Inst. (Trans. Thermo-Tech. Inst. (Russia))* 1928, No. 4, 58-66.—Russian standards for lubricating oils for steam engines working on satd. steam.

Oil	Sp. gr.	Minimum flash open cup	Viscosity E° ₁₀₀	Max. for asphalt and ash
Cylinder				
2 bright	0.890-0.920	220°	1.8-2.2	ash not over 0.05
Nigrol L.				
dark	0.915-0.945	240°	5.0-7.0
Viskozin				
3 dark	0.910-0.925	240°	3.0-4.0	0.3%
Viskozin				
5 dark	0.915-0.930	255°	5.0-6.0	0.4%
Vapor L.				
dark	0.895-0.910	265°	3.5-4.5	0.3%
Lubricating oils for superheated steam engines				
Vapor L.	0.895-0.910	285°	3.5-4.5	0.3%
Vapor M	0.900-0.915	300°	4.5-5.7	0.4%
Vapor T	0.905-0.920	320°	5.5-6.7	0.5%
T-Extra	0.905-0.920	330°	6.0-7.0	0.5%
Viskozin 7	0.920-0.930	300°	7.0-8.0	0.5%
Viskozin 10	0.925-0.940	325°	not below 9.5	0.6%
Cylinder oils or steam engines working on saturated steam				
Viskozin 3	240°	3.0-4.0	0.1%
Viskozin 5	240°	5.0-6.0	0.15%
Vapor L.	280°	4.0-5.0	0.15%
Nigrol L.	240°	5.0-7.0	0.3%
Mineral acids and mechanical admixtures, none				
Cylinder oils for steam engines working on sup				
Vapor L.	280°	4.0-5.0	0.15%
Vapor T	320°	5.5-6.5	0.20%
Viskozin 7	300°	7.0-8.0	0.20%
Mineral acids and mechanical admixtures, none				

Uses of the above oils under various conditions are given. Specifications for bearing oils of the "Neftesindikats" are: machine oil No. 2, sp. gr. 0.890–0.915, open-cup flash not below 190°, viscosity E_{100} 5.5–6.5, sodium test not below 3, cold test not above -8° ; machine oil "T," bearings of steam engines and the main shaft, for heavy loads and medium speed of rotation, sp. gr. 0.895–0.918, open-cup flash not below 200°, viscosity E_{100} 7.0–8.2, sodium test not below 3, cold test not above -5° ; marine "L," sp. gr. 0.915–0.922, open-cup flash not below 205°, viscosity E_{100} 8.0–8.5; marine "T," sp. gr. 0.918–0.925, open-cup flash not below 215°, viscosity E_{100} 9.5–10.5. The last two oils are as a rule compounded with some vegetable oil to make them emulsify with water.

A. A. BOEHTLINGK

• Benzine for asphalt precipitation. H. BURSTIN AND J. WINKLER. Galicia Naphtharaffinerie, Drohobycz. *Erdöl u. Teer* 5, 26–8, 42–4, 62–4 (1929); cf. C. A. 22, 4786; 23, 1258.—For the prepn. of asphalt-pptg. benzine, corresponding to the requirements stated in Holde (Kohlenwasserstoffol u. Fette, 6th ed., p. 135), the exclusive use of American raw oil is not necessary. Suitable raw materials for the purpose were discovered also in benzines from Polish crude oil, in a natural-gas gasoline and cracked gasoline. Pptn. benzines, meeting the specifications, can be prepd. which do not have the same pptg. powers. On this account more precise conditions for asphalt-pptg. benzine are proposed.

F. S. GRANGER

Determining the penetration of asphalts. EDMUND GRAEFE. *Petroleum Z.* 24, 1599–1603 (1928).—Various types of penetrometers and methods of operation are described.

M. B. HART

Transformations undergone by pine stumps in the ground after cutting of the tree. G. DUPONT AND M. SOUM. Inst. du Pin, Bordeaux. *Bull. inst. pin* No. 55, 313–22 (1928).—The stump of a 65-yr. pine, cut 14 yrs. previously and found in slightly moist sand, looked like rotten wood, and could be crushed between the fingers and kneaded into a plastic, putty-like mass. From the appearance of the wood, which had practically kept its original vol., it had lost little in wt. since the tree was cut. It contained 11.7% of H_2O and 73.38% of (83.10% on the dry basis) Et_2O ext. The complete analysis on the dry basis was: ash 0.22, normal cellulose 0.33, incrusting matter (lignins) 21.75, pine oil 21.56, rosin acids 38.67, oxidized acids 1.35, free $AcOH$ 0.60, non-volatile H_2O -insol. acids 1.48, fats and esters 3.18, loss and undetd. 4.86%. The properties of the lignin had changed, but the proportion was of the same order of magnitude as in fresh wood. The cellulose had almost entirely disappeared, and since the wood had not undergone any great loss in wt., cellulose had probably been converted into resinous compds. Certain portions of the wood contained mycelia of a fungus that are possibly the cause of this transformation. D. and S. designate the product as "resinose." A fossil pine stump bored by marine erosion in the coastal regions of the Landes regions, which had probably been buried for centuries, had the appearance and properties of ordinary heartwood, gave the chief color reactions of lignin, and had the following compn.: H_2O 1.00, rosin acids (as $C_{20}H_{30}O_2$) 0.065, neutral Et_2O ext. 4.915, of which at least 2.5 was pure retene, total cellulose 47.27, lignin 35.66, ash 1.97%, other constituents undetd. About the only important difference from fresh wood was the presence of a large amt. of retene. It is suggested that the phenomena involved in the transformation of the 2 stumps are involved in the formation of coal beds.

A. PAPINEAU-COUTURE

The determination of active oxygen in oxidizing Russian turpentine. K. N. KOROTKOV. *Zapiski Belorusskoi Gosudarst. Akad. Sci'skogo Khimyaistva*. (Memoirs Belorussian State Acad. Agr.) 5, 16–24 (1927).—Turpentine dissolved in water acidified with small quantities of dil. H_2SO_4 was tested for its active O kept under conditions of (1) sun-light, (2) darkness and (3) darkness with frequent exposures to elec. light. The O was detd. on a 80 cc. sample with fresh MnO_2 as a catalyst. The Russian turpentine had a higher oxidizing value than the French. The sun is the chief factor responsible for the oxidation of the turpentine. In the dark with frequent exposures to elec. light the oxidation is less extensive. The products of oxidation sol. in water are stable compds. and are not decompd. upon heating; these products are not H_2O_2 . The oxidizing property of the turpentine soln. upon standing a month was not lost. The amt. of O obtained may be designated as the "oxygen number" of the turpentine.

J. S. JOFFE

New coating for stills (MORRELL, *et al*) 13. Petroleum wash-oil thickening in the scrubbing of gas (ULLMANN, *et al*) 21. Use and behavior of protective coatings on underground pipes (SCOTT) 13. Study of the action of Fe catalyzers on mixtures of CO and H (AUSTIN, RAINBOW) 2. Progress report of pipe line and

production of the A. P. I. general committee on corrosion for 1928 (Bly) 13. Pyrogenic decomposition of hydrocarbon materials (Brit. 296,034) 21. Apparatus for separating oil and water by gravity (U. "Cracking" petroleum oils. ALEXANDER SAKHANOV and MISTISLAV TILICHE'EV. Fr. 645,879, Dec. 17, 1927. The oils at the desired high pressure are led through 2 groups or sets of tubes in a chamber heated to the desired temp., the 1st set (the heating tubes) being of much smaller diam. than the 2nd (the reaction tubes).

Petroleum oil fractions. ALLGEMEINE GES. FÜR CHEMISCHE INDUSTRIE. Brit. 295,253, May 7, 1927. Gasoline or other petroleum products are sepd. into fractions, one of which boils below about 160-70° and the other above this temp., and unsatd. hydrocarbons are dissolved from the fraction of higher b. p. by liquid SO_2 or acetone, or a mixt. of both, and are added to the fraction of lower b. p. The satd. hydrocarbons remaining may be added to "illuminating oil."

Refining petroleum. AXTELL RESEARCH LABORATORIES, INC. Fr. 646,134, Dec. 23, 1927. Mineral oils have their S content reduced by a treatment with oleum satd. with an aromatic hydrocarbon, preferably of the C_6H_6 series, whereby sulfonation, oxidation or polymerization of the oil is prevented. Cf. C. A. 22, 3984.

Removing sulfur compounds from petroleum oils. WILLIAM N. DAVIS, WILLIAM H. HAMPTON and EDWIN N. KLEMGARD (to Standard Oil Co. of Calif.). U. S. 1,705,800, March 19. Cracked petroleum naphtha or other similar high-S petroleum distillates to be desulfurized are treated with H_2SO_4 and the polymerization of unsulfured compds. is reduced by use of an acid of lower freezing point than the treating temp. and effecting the treatment at a temp. of about 3° or lower. An arrangement of app. is described.

Petroleum sulfonic acids. PETER I. SCHESTAKOFF. U. S. 1,706,940, March 26. In order to isolate oil-sol. sulfonic acids, a sulfonated petroleum oil is treated with a water-sol. ester of HOAc such as MeOAc to dissolve the sulfonic acids.

White petrolatum. ERNEST B. COBB and AUGUST HOLMES (to Standard Oil Development Co.). U. S. 1,707,187, March 26. A petrolatum-yielding stock is dissolved in a solvent such as naphtha and the soln. is treated with fuming sulfuric acid, the sludge produced is withdrawn and the solvent and pure petrolatum are sepd. by distn. An arrangement of app. is described. Iso-Pr alc. may be used to ext. sulfonic compds.

Cracking hydrocarbon oils. JOHN C. BLACK (to Gasoline Products Co.). U. S. 1,706,396, March 26. The oil is heated in a series of tubular heaters such as pipe coils, in one of which the oil is brought to an active cracking temp. while in another the oil is further subjected to prolonged heat treatment while maintaining the temp. by supply of heat to compensate for that rendered latent by the endothermic reactions taking place; the heated hydrocarbons are then mixed with an addnl. supply of hydrocarbons at a lower temp. and the mixt. is subjected to a final heat treatment to effect cracking. Sufficient pressure is maintained on the material to prevent substantial vaporization. An arrangement of app. is described.

Cracking hydrocarbon oils. I. G. FARBENIND. A. G. Brit. 295,074, April 21, 1927. An app. is described in which oils are cracked by heating them with an elec. resistance heater which is immersed in the liquid and exposed to intermittent or continuous blasts of gases supplied through a pipe extending into the liquid. The gases may contain O, H, or gases and vapor capable of giving off H but free from C. Various exemplary details are given. Cf. C. A. 23, 2028.

Cracking hydrocarbon oils by the "tube and drum" method. A. C. SPENCER and E. W. LUSTRA (to Standard Oil Development Co.). Brit. 295,399, Aug. 11, 1927. Condensate from an intermediate stage is led away, reheated and returned to the unit from which it was taken. An arrangement of app. is described.

Purifying hydrocarbon oils. LAMUEL M. JOHNSTON and JAMES L. FARRELL. U. S. 1,706,614, March 26. In treating oils such as "cracked gasoline," a treating material such as fuller's earth or bentonite is formed into a paste or mud and strings of the latter are accumulated to form a porous column through which vapors of the oil are passed. An app. is described.

"Sweetening" hydrocarbon oils. H. G. M. FISCHER (to Standard Oil Development Co.). Brit. 295,728, Aug. 19, 1927. Oils such as kerosene are agitated with Na plumbite, blown with an O-contg. gas such as air, and S is added at intervals during the blowing. The mixt. is allowed to settle, the aq. layer is drawn off, and the oil is washed with water.

Removing paraffinic substances from hydrocarbon oils. ROBERT S. LANE (to Standard Oil Co. of Ind.). U. S. 1,706,120, March 19. In order to remove petrolatum from oil it is mixed with butanol and acetone, cooled and the waxy material sepd.

Cracking oils. JOHN R. MARDICK (to Universal Oil Products Co.). U. S. 1,706,629, March 26. Oil such as gas oil is heated and subjected to the action of previously electrically activated Cl in the absence of sufficient moisture materially to interfere with the cracking of the oil, and products of low b. p. are collected. An arrangement of app. is described.

Cracking oils. "LE CARBONE." Fr. 646,268, May 14, 1927. Active C at atm. pressure and a moderate temp. is used as catalyst in the transformation of mineral or vegetable oils to produce lighter oils.

Distilling and cracking oils. S. SEELIG. Brit. 296,000, Aug. 22, 1927. Distn. and cracking of oils contg. impurities such as resins or benzene is effected by passing them continuously through a molten metal bath, and clogging of the reaction vessel is prevented by pumping the oils from the source of supply through an asphalt separator and then distg. off the benzene (under slightly increased or diminished pressure) before passing the oils to the reaction vessel. Cf. C. A. 22, 1468.

Cracking oils and producing oil gas. A. FECHTER and P. BURGER. Brit. 295,938, Aug. 20, 1927. An app. is described in which a mixt. of hydrocarbons and H is ignited by an elec. sparking device.

Apparatus for making oil gas. N. A. MAL'VINSKII. Russ. 5525, May 31, 1928.

Distilling oils by a bath of molten metal. S. SEELIG. Brit. 295,935, Aug. 20, 1927. Direct contact of oil with the heated wall surrounding the bath of molten metal is prevented by an inner wall spaced from the outer wall to form an annular space through which a current of air may be circulated. The inner wall has pressure-equalizing openings, and the oil may be introduced by means of a coiled tube adjacent the inner wall. Cf. C. A. 22, 1232.

Distilling plant for heavy oils. SOC. DES ÉTABLISSEMENTS BARBET. Fr. 646,248, May 12, 1927.

Heavy mineral oils. ERDÖL- UND KOHLE-VERWERTUNG A.-G. Ger. 469,228, June 15, 1921. Heavy mineral oils, with or without distn or purification by C, are desulfurized and hydrogenated by treating with alkali metals under H pressure at about 300°, in order to disrupt the mols. Porous material such as wood charcoal or powd. coke can be added. Thus, granular dried mineral coal is heated with coal-tar oil and a little metallic Na in an autoclave. After several applications of compressed H, the disruption is so general owing to the coal that only 8% of the residue is unchanged. The product is distd. off for motor fuel.

Tunnel retort for the distillation of carbonaceous materials such as oil shale or coal.

HARRY M. ROBERTSON. U. S. 1,706,128, March 19. Structural details.

Rotary retort apparatus for distilling oil shale or other carbonaceous materials.

INTERNATIONAL BITUMEN-OIL CORP. Brit. 295,225, April 5, 1927. A rotary retort is described which is divided into zones of increasing temp.; the hot gases for internally heating each zone are used for heating a series of stills, each working at a different temp., through which oil from the retort charge is passed in series.

Clarification of benzine. JEAN J. WACK. Fr. 646,721, Jan. 5, 1928. Benzine is clarified by sapon. the oils and fats contained therein in the state of emulsions, by means of an alk. soln. into which the benzine is injected in an atomized condition. NaCl may be added to the alk. soln. (e. g., Na_2CO_3) to accelerate the sepn. of the emulsions. An app. is described. Cf. C. A. 23, 1515.

Lubricating oil. H. L. CALLENDAR, R. O. KING and E. W. J. MARDLES. Brit. 295,230, May 4, 1927. A heat-resisting lubricating oil comprises mineral, animal or vegetable oil together with a small proportion of Et_2Pb or similar Pb aryl or alkyl compd. which is sol. in the oil. An org. halogen compd. such as ethylene dibromide also may be added to counteract any deleterious effects which the treated oil might otherwise have.

23—CELLULOSE AND PAPER

CARLETON E. CURRAN

V

The cellulose industry and its products of manufacture. G. K. BERGMAN. III. *Nord. Kemistmötet* (Finland) 1928, 143-66.—An historical account of the cellulose industry in Finland during the last 75-80 yrs. Spruce or white fir, the main source for cellulose, has the following compn.: cellulose 53, hemicellulose 15, lignin 30, albuminates, oils, minerals, etc., 2%. Processing of wood for cellulose consists essentially in removing non-cellulose constituents, chiefly lignin. The quality of the finished product depends largely on the amt. of lignin present. There is a brief discussion of methods for detg. the adhesiveness of cellulose or the strength of paper. B. discusses Nägeli's micellular theory, which assumes that cellulose fibers are composed of minute cells made up of crystals with the following approx. dimensions: 7.9, 8.45 and 10.2×10^{-8} cm. It has also been shown that the crystal vol. can contain 4 dextro groups, making cellulose $(C_6H_{10}O_5)_4$. Chem. evidence as well as phys. evidence (photographing with monochromatic Röntgen rays) are given in support of the theory. The different opinions relative to lignin and cellulose are discussed. One group maintains that lignin is a by-product obtained from the sap of plants during growing periods, while others think that this product is in chem. combination with carbohydrates, e. g., esters. Nine photomicrographs are given, showing cellulose fibers after treatment with different reagents. O. A. NELSON.

The amphoteric character of cellulose and the relation to its purity. KYO KAWAMARU. Kiryu Higher Tech. School. *J. Textile Ind.* 4, 259-84(1928). Two g. samples each of purified standard cotton cellulose, oxycellulose, hydrated cellulose, nitrated and acetylated cellulose were dipped into 20 cc. of Clark's buffer soln. of various pH values; after equil. was attained the change in the pH value of the soln. was measured to det. the amphoteric character of the sample. The influence of various impurities likely to occur in cellulose was also examd. Ordinary cellulose contains firmly bound alkali and shows an amphoteric character corresponding to the alkali content, with its apparent isoelec. point on the acidic side. After acid treatment, the isoelec. point is on the acid side, while after alkali treatment and washing with H_2O , the isoelec. point shifts to the alk. side. Ordinary cellulose contains some decomposed or transformed cellulose, which influences the amphoteric character markedly. Oxycellulose has an acidoid, and hydrated cellulose a basoid character. As the result of the influence of these impurities ordinary cellulose behaves as an amphoteric substance, which has its isoelec. point at some definite acidity or alkyl. K. SOMMER.

The chemical analysis of cotton. The determination of cellulose by oxidation with chromic acid. CONSTANCE BIRTWELL and BERT P. RIDGE. Shirley Institute, Bolton. *J. Textile Inst.* 19, 341-8T(1928).—A description is given of the exact conditions, procedures and app. adopted by the Shirley Inst. for the oxidation of cellulose and its detn. by both the gas-volumetric and the titrimetric methods. For the former method, the procedure of Berl and Innes with slight modifications is used and is accurate for weights of carbohydrate from 0.01 to 0.1 g. A mixt. of H_3PO_4 and CrO_3 is a satisfactory oxidizing agent except when the cellulose content of the sample is low and the diln. of the H_3PO_4 slows up the oxidation rate. In such a case, H_2SO_4 is more satisfactory and the formation of SO_2 is avoided by taking care to provide for the excess of CrO_3 throughout the analysis. In the titrimetric method, the sample is boiled with excess standard $K_2Cr_2O_7$ and H_2SO_4 for about 1 hr.; the excess $K_2Cr_2O_7$ is either detd. iodometrically or titrated against standard $Fe(NH_4)_2(SO_4)_2$ with ferrixyanide as external indicator. To avoid loss of O_2 by decompn. of CrO_3 , the reaction mixt. should not contain more than 1 vol. of concd. H_2SO_4 to 1 vol. of aq. soln., the proportion generally employed being about 1 vol. of acid to 3 vols. of aq. soln. The accuracy of both methods is shown by the results of the application of each to the combustion of bleached cotton, starch, cellulose in cuprammonium soln., and modified cell papers in NaOH soln. RUBY K. WOESLER.

The form and size of the micelles of cellulose and rubber. J. HENCKENBERG and H. MARK. *Z. Krist.* 69, 271-84(1928).—The principles underlying the detn. of the size and form of small particles by the Laue method are investigated and discussed. Measurements on cellulose, rubber and artificial silk show micelles elongated parallel to the fiber axis. From photographs taken at the temp. of liquid air it was found that the coeff. of expansion for the direction parallel to the fiber axis is considerably smaller than that at right angles to the axis. L. S. RAMSDALL.

Transformations undergone by pine stumps in the ground after cutting of the tree (DUPONT, SOUM) 22. Effect of temperature on the viscosity and ease of precipitation of sols of cellulose acetate (WHITBY, GALLEY) 2. Esters of polycarboxylic acids [for use as solvent for nitrocellulose] (U. S. pat. 1,706,639) 10. Molded receptacles of wood pulp and casein (U. S. 1,705,780) 18. Purification of alkaline lyes (Fr. pat. 646,942) 18. Adhesives containing cellulose esters (Brit. pat. 295,366) 18. Different tints on paper (Brit. pat. 295,778) 25. Resins; paper (Fr. pat. 646,170) 26.

Sheets or films of cellulose derivatives, etc. NON-INFLAMMABLE FILM CO., LTD., and H. J. MALLABAR. Brit. 295,797, June 27, 1927. Sheets or films with a matt surface are prepd. by casting celluloid, cellulose acetate or like compn. on a sheet or band (which may be formed of polished metal) having a matt surface prepd. by coating it with a layer of gelatin impregnated with starch, BaSO₄, fine Kieselguhr, or like materials.

Films. SPICERS, LTD. Fr. 645,912, Dec. 19, 1927. Films contg. esters or ethers of cellulose are freed from residual solvent and elec. charges by passing them through a space kept moist with steam.

Cellulose ethers. LEON LILIENFELD. Ger. 470,142, May 22, 1912. Derivs. or transformation products of cellulose, sol. in alkali, are treated with alkylating agents, especially alkyl esters of inorg. acids, in the presence of a basic substance. Thus, crude viscose is diluted with water and allowed to congeal in a water bath. It is then dissolved in 50% NaOH, diethyl sulfate added and the whole heated. Hot water is added and the mixt. acidified with dil. H₂SO₄ when the ether is pptd. Other examples are given.

Plastic compositions from cellulose ethers. I. G. FARBERIND. A.-G. Brit. 295,940, Aug. 19, 1927. Cellulose ethers such as ethylcellulose are kneaded with an alc. of the terpene series such as isoborneol (or the waste oil contg. fenchol and borneol produced in the manuf. of camphor), solvents and softening agents such as C₆H₆ or alc. also may be added. The material may be rolled, allowed to dry, comminuted and then subjected to hot pressing (a temp. of 125° being suitable). Benzyl alc. and isobutyl phthalate may be used in the compns.

Use of carbon disulfide as a solvent with cellulose derivatives. I. G. FARBERIND. A.-G. Brit. 295,942, Aug. 19, 1927. In making films, fibers, etc., a cellulose ester or ether, e. g., a benzene-sol. triethyl cellulose, is dissolved with CS₂, which may be used with other suitable solvents such as C₆H₆ or acetone.

Method of charging digesters and cellulose extractors by a current of gas. PER ALBERT FRESK. Fr. 645,961, Dec. 20, 1927.

Means for distributing viscose. WERNER CHATELAIN. Ger. 471,291, Feb. 14, 1928.

Artificial silk. ALBERT WAGNER (to the Firm Fr. Kuttner). U. S. 1,706,717, March 26. In producing fine fiber artificial silk, strands are first formed from a soln. of ammoniated Cu oxide cellulose by the stretch spinning method; these strands are treated in a bath contg. (NH₄)₂SO₄ soln., wound on spools or the like, then washed, treated with H₂SO₄ and further washed and dried.

Artificial silk. CURRUM SOC. ANON. Fr. 645,102, Dec. 23, 1927. In making artificial threads by drawing or spinning cuprammoniacal soln. the threads are led, during acidification, through thread-guides placed in the channels and having a perfectly uniform profile, their position being adjustable.

Artificial silk. "CURRUM" A.-G. Swiss 128,200, July 27, 1927. Strong fibers are formed by causing two or more contiguously spun filaments to stick together.

Artificial silk. HENRY DAVYD. Fr. 645,918, Dec. 19, 1927. Construction of spinning app. and pumps therefor.

Artificial silk. GRUNERT & GIANNETTI. Fr. 645,972, Dec. 20, 1927. See Brit. 282,670 (C. A. 22, 3777).

Artificial silk. NAAMLooZE VENNOOTSCHAP NEDERLANDSCHE KUNSTZIJDEFABRIEK. Fr. 646,850, Nov. 29, 1927. Artificial silk possessing good mechanical properties is made by submitting the thread after spinning to a gradually increasing tension, which is obtained by a long immersion of at least 50 cm. and by a long zig-zag path through the air over 5 or more rotating rollers before reaching the bobbins. Cf. C. A. 23, 2034.

Hollow filaments of artificial silk. HANS KARPLUS. U. S. 1,707,164, March 26. Solns. such as those of viscose, cuprammonium cellulose, cellulose acetate, or nitro-cellulose, before being spun, are incorporated with liquid or solid org. noncryst. substances such as bone oil, paraffin oil, or Na oleate, which during the following spinning and finishing operations do not produce bubble-forming gases or vapors; these substances are subsequently removed from the threads formed by use of suitable solvents.

Apparatus for making artificial silk filaments. I. G. FARBENIND. A.-G. Brit. 296,063, Aug. 25, 1927.

Apparatus for making artificial silk filaments from cellulose acetate solutions by the dry spinning method. SCIENTIFIL. Brit. 295,354, Aug. 10, 1927.

Spinning centrifuge for artificial silk. V. BLAESS. Brit. 296,104, Aug. 25, 1927.

Three-phase pump for artificial silk manufacture. ERNEST LUNGE and COURT AULDS, LTD. Ger. 471,217, Nov. 20, 1925. See Brit. 248,039 (C. A. 21, 650).

Pulping wood. FRANCIS G. RAWLING. U. S. 1,705,827, March 19. Wood is treated with solns. contg. Na sulfite, NaHCO_3 , or other suitable Na salt of a weakly ionized polybasic acid, and an excess of CO_2 , at temps. up to 190° , in order to obtain a pulp which is of light color.

Bleaching "chemical wood pulp." LINN BRADLEY and EDWARD P. McKEEFE. U. S. 1,705,897, March 19. Wood pulp such as that produced by cooking wood with alk. solns. is treated with a dil. acid such as a 0.5-1% HCl soln. and then with an alk. hypochlorite soln.

Paper. UMBERTO POMILIO and GIULIO CONSIGLIO. Fr. 646,154, Dec. 24, 1927. Straw, maize stalks, hemp, etc., are made into a semifine paper by a short preliminary treatment with dil. alkali or warm water under pressure, followed by a rapid incomplete chlorination with gaseous Cl.

Paper pulp. R. W. HOVEY. Brit. 295,759, May 23, 1927. A digester construction and steam and liquor circulation system are described. The charge of pulp may be undercooked to retain a portion of the liquid of the lignins, pentosans and sugars; the fibers are passed through a screen and those retained by the screen are reduced by a mech. device, which is described. Cf. C. A. 23, 514.

"Refining engine" for treating paper pulp. LUDWIG H. WESSEL (to Hermann Mfg. Co.). U. S. 1,706,944, March 26. Structural features.

sizing and impregnating paper. I. G. FARBENIND. A.-G. Brit. 295,288, Aug. 8, 1927. The effects obtained by the process described in Brit. 293,000 (C. A. 23, 1507) are modified by first coloring, sizing, impregnating, or otherwise treating the whole of the pulp or a portion of it from which the paper is made and afterward treating the paper as described in Brit. 293,000.

Impregnating paper with rubber or similar substances. REED P. ROSE and HAROLD E. CUDR (to General Rubber Co.). U. S. 1,705,537, March 19. Cotton fiber is cooked with Na_2CO_3 soln. to remove fats, oils, waxes and other noncellulosic substances without impairing the strength of the fiber, and formed into sheets; the latter are treated with a dispersion such as rubber or glue-glycerol compn.

De-inking printed newspaper. JENNINGS DEWITT. U. S. 1,705,907, March 19. The printed paper is soaked in a soap soln. for about 2 hrs., subjected to a shredding operation for about 15 mins., soaked while at rest for about 1 hr., further shredded for about 30 mins. and then subjected to shredding and washing for about 15 mins.; fluid material is sponged from the pulp. An app. is described both in this pat. and in U. S. 1,705,908, which relates to similar procedure.

Waterproof paper. ALBERT L. CLAPP (to Bennett, Inc.). U. S. 1,706,840, March 26. A sol. straight-chain fatty-acid soap such as Na stearate or Na oleate is incorporated into paper pulp together with Na silicate; a metal salt such as $\text{Al}_2(\text{SO}_4)_3$ or alum is added in sufficient quantity to ppt. both the soap and the Na silicate; the pulp is formed into paper. U. S. 1,706,841 specifies production of a waterproof and greaseproof paper by incorporating, with the paper-making pulp glue, an aq. dispersion of waterproofing material such as a wax, bitumen, or resin and Na silicate, and by adding Al sulfate as a pptg. agent to form a voluminous ppt. of Al silicate and to cause the glue and dispersed material to be fixed on the pulp.

24—EXPLOSIVES AND EXPLOSIONS

C. E. MUNROE

Table of common hazardous chemicals. NATIONAL FIRE PROTECTION ASSOC. 11 pp.—This table was prepd. by a Comm. of the Natl. Fire Protection Assoc. in conjunction with a similar comm. from the Am. Chem. Soc. and under the headings name, usual shipping container, fire hazard, life hazard, storage and remarks gives information from the fire protection standpoint for some 60 substances. The statements are tentative and this list constitutes the revision up to Jan., 1929. C. E. M.

Study of powders heated in dry and humid atmospheres at 75°. M. MARQUEYROL. *Mém. poudres* 23, 128-46(1928).—For samples heated in a dry atm. at 75°, the speed of denitration and decompn., whether in open or closed containers, was the same for both BAM and BD powders. Tests showed much greater denitration at 163 days when BAM and BD powders were mixed than at 280 days in which individual powder lots were kept sep. In a moist atm. the Am alc. powders became white, opaque, brittle and acid. Thirty days heating was without effect, but renewal of the air in the containers or aeration of the powders markedly accelerated their decompn. The diphenylamine powders were 3 times as stable as the Am alc. powders under the same conditions. Decompn. of the powders took place more rapidly when pure water was used in the containers (to furnish a humid atm.) than when 1.246° H₂SO₄ was employed. Analyses of the gases formed by heating the powders in tubes sealed with Hg and collecting the gases over Hg showed that NO is a very minor constituent of the evolved gases. Alc. nitrites were found present, more in the BAM than in the BD powders. The theory that decompn. is caused by the action of nitrous vapors formed from the interaction of NO and O is held untenable because of the very small quantity of NO liberated from the powders. Renewal of the air over the powders hastens decompn. and for this reason leaky containers are to be avoided. Thick strip powders, in every case, were denitrated more rapidly than thin strip powders. Thick BD strip powders were less rapidly affected than thick BAM strips. This is attributed to some action between alc. and nitrocellulose. Further work is promised. A. J. PHILLIPS

Analysis of deteriorated BD grains. M. DESMAROUX. *Mém. poudres* 23, 124-7 (1928).—Two diphenylamine-stabilized grains which had the appearance of decompd. BAM grains were examd. for color reactions with α -naphthylamine, KOH and KCN. The results showed unchanged diphenylamine in the interior and amine compds. on the surface which had been partly volatilized during the heating at 75°. A. J. P.

Analysis of BAM and BD powders. M. DESMAROUX. *Mém. poudres* 23, 116-23 (1928).—Total volatiles were measured after a water pptn. of the powder dissolved in ether-alc., followed by drying for 4 hrs. at 108.5°. For the diphenylamine powders, drying of the pptd. nitrocellulose in vacuum desiccators over H₂SO₄ was employed. For diphenylamine content the powders were pulverized, extd. with ether and the ether residue was taken up with chloroform, dried and weighed. Viscosity tests were made with 0.2% solns. in acetone, as compared with pure acetone, in a Kling viscometer at 15°, to see if indications could be obtained as to the mol. disintegration of the nitrocellulose during heating. Figures were submitted but without interpretation. N was detd. in a nitrometer and showed a drop from about 12.4 to 11.4%. Soly. was measured by pptg., drying and weighing the nitrocellulose in an aliquot portion of an ether-alc. soln. which was centrifuged after standing for 48 hrs. Heating caused the solubilities to increase from about 55 to 94%. A. J. PHILLIPS

Chemical and ballistic stability of BAM and BD powders. M. MAURIN. *Mém. poudres* 23, 70-112(1928).—Smokeless powders stabilized with 8% of Am alc. (BAM) and 2% of diphenylamine (BD) were heated for 170 and 185 days in water-jacketed containers at 75°. Observations made during the heating showed that the violet ink of the recording thermometers, the metallic parts of the thermometers and the linings of the containers were oxidized. Dry litmus paper in the heaters showed that the gases disengaged were acid in character. Up to 59 days the BAM powders remained a dark gray and then turned a pale yellow and became much more transparent. The BD powders blackened after 23 days and developed red spots. All powders remained flexible up to 23 days and became very brittle after 122 days. The loss in weight after 185 days was about 9% for the BAM powders and 5-6% for the BD powders. The coeff. of elimination for BAM powders increased rapidly after 59 days while with the BD powders it remained almost const. The coeff. of emission remained almost const. for all powder. All were much more hygroscopic after removal from the heaters. The coeff. for the rate of burning in a bomb decreased rapidly for the BAM powders and

increased slightly for the BD powders. In ballistic tests the BAM powders lost 10% of their speed and 20% of their pressures, while the BD powders retained or slightly increased their ballistic characteristics (speed, pressure and uniformity). A. J. P.

Transformation products of centralite in stored SD powders. H. LECORCHE AND P. L. JOVINET. *Mém. poudres* 23, 147-54(1928); cf. C. A. 22, 3779.—This study is concerned with the products formed which are non-volatile in steam. They are mononitro centralite and *p*-nitronitrosamine. *p*-Nitroethylphenylnitrosamine is volatile with steam but is converted into a non-volatile material when the nitrocellulose and nitroglycerin are hydrolyzed by soda for analytical purposes. As an index of the age of a powder, ethylphenylnitrosamine is detd. colorimetrically with alc. α -naphthylamine. Standards for comparison are made with alc. nitrosodiphenylamine and α -naphthylamine. Conclusion: Centralite is a better stabilizer than diphenylamine in the presence of nitroglycerin. A. J. PHILLIPS

Dust explosions. R. LOCH. *Z. Ver. deut. Ing.* 73, 247-9(1929).—A review of the literature and safety precautions in grinding. E. M. SYMMES

Flame propagation in the gaseous mixtures. YOSABURO NAGAI. Tokyo Imperial Univ. *J. Fuel Soc. (Japan)* 8, 145-62(1929).—The theory and mechanism of flame propagation are discussed. F. I. NAKAMURA

Ignition of gas by spark and its dependency on the nature of spark. TORAHIKO TERADA AND KIYOHiko YUMOTO. Inst. Phys. Chem. Research, Tokyo. *Proc. Imp. Acad. (Japan)* 4, 467-70(1928).—Morgan (C. A. 17, 2505, 19, 1982) inferred that the "capacity spark" is in general more effective in igniting the combustible gas mixt. than the "inductance spark." Results are reported with a mixt. of 16% CO and 84% air, satd. with water vapor at 25.7°; a 100 v. 1 kw. transformer being used for the excitation of the spark, ignition is completed when the primary current is greater than 2.0 amp., though the luminosity of the spark is rather faint; when a parallel capacity is inserted, a primary capacity of 4 amp. is insufficient for ignition, notwithstanding the remarkable brightness of the spark, with a series resistance the luminosity of the spark becomes fainter but ignition takes place whenever a spark is passed. Thus whether or not the flame will be extinguished or propagated depends upon the balance between the heat evolved and that lost during the period of "indecision" (0.01 sec.). C. I. W.

Auto-ignition temperatures of flammable liquids. NORMAN J. THOMPSON. Factory Mutual Laboratories, Boston. *Ind. Eng. Chem.* 21, 134-9(1929). The development of the app. is described and the effect of different constructional materials on ignition temps. is shown. Data for 37 org. liquids as detd. in app. of 6 comp. are given. ALDEN H. EMERY

Firedamp explosions within closed vessels. "Pressure piling." C. S. W. GEIGL AND R. V. WHEELER. *Safety Mines Research Board* (London), paper No. 49, 2-13 p. (1929).—This records results of a further study of the magnitude of the pressure developed in firedamp explosions within closed vessels such as the casings of elec. switch gear used in coal mines. In these expts. explosions of CH_4 + air originated in one vessel were allowed to travel through a small opening into another vessel similarly filled. In one set of tests the coupled casings differed in the ratio of 10 to 1 and in the second set by 100 to 6. From the results of the second set it is concluded that when an explosion from CH_4 + air travels from a relatively large vessel through a small opening into a relatively small vessel the pressure developed in the latter will be materially increased over that normally developed by a CH_4 + air mixt. initially at atm. pressure. C. I. M.

Controlling fire and explosion hazards of anesthetics. C. H. WARDLE. *M. J. Hosp.* 32, 50(1929). *Squibb Abstr. Bull.* 2, 137. Static electricity, one of the special hazards encountered in anesthetics, may be best controlled by the use of a proper humidification system, i. e., the relative humidities existing in surgeries should not be below 55%, and by the use of anesthesia equipment that has been made internally conductive to static by means of moisture and metallic devices. Some of the other precautions to be observed are the prohibition of open flames, or any source of ignition in the operating room; the use of vapor-proof type of elec. lights and switches; loose connections, worn elec. light cords, etc., should be eliminated. It is stressed that the effectiveness with which the fire hazards often occurring with such combustible anesthetic agents as Et_2O , ethylene, EtCl and mixts. of CHCl_3 and Et_2O may be reduced depends primarily upon the maintenance of humidity. A study of the phys. properties of ethylene and Et_2O has led to the conclusion that one is about as dangerous as the other with regard to flammability hazard. C. R. F.

HERBERT C. BUGHARD. U. S. 1,706,871, March 26. In prep. granular carbonized lignin residues (such as those obtained from waste soda pulp

liquor) for use as an absorbent for liquid O, the material is leached to remove substantially all water-sol. inorg. substances and to reduce the proportion of incombustible constituents to a minimum, and the grains of the carbonized material are reduced to such a size that their d. will be at least equal to about 0.20 and their degree or absorptiveness for liquid O at least equal to 2.6 times their own wt.

Blasting explosive. LEAVITT N. BENT (to Hercules Powder Co.). U. S. 1,706,517, March 26. Explosive ingredients such as NH_4BO_3 , NaNO_3 and nitroglycerin are used with spruce, pine or other wood normally of high d. which has been disintegrated by the release of high internal pressure.

High explosive. FREDRICH OLSEN. U. S. 1,705,874, March 19. An explosive which is suitable for use in hand grenades is formed from NH_4ClO_4 32, $\text{Ba}(\text{NO}_3)_2$ 28, vegetable-ivory meal 14, ferro-Si 10, trinitrotoluene 15 and graphite 1%.

Recovering explosives from shells. JOSEPH H. ROBERTS (one-half to Frank W. Olin). U. S. 1,706,938, March 26. In order to recover an explosive contg. NH_4NO_3 80 and trinitrotoluene 20% from shells, heated 95% alc. is run in the shells, the soln. formed is drained off and cooled to effect crystn. of the explosive which is then dried. An app. is described.

Rendering explosives nondeliquescent. LLEWELLYN J. W. JONES (to James F. O'Brien). U. S. 1,706,668, March 26. In prep. explosives with ingredients such as NaNO_3 contg. deliquescent impurities such as MgCl_2 and CaCl_2 , the material is mixed with dehydrated Na_2CO_3 , ground and dried, and the dried mixt. is coated with a mixt. of liquid nitrotoluenes.

Blasting fuses. J. FRITZSCHE. Brit. 295,406, Feb. 7, 1927. As a covering for the core of fuses there is used a material formed at least in part from prevulcanized rubber such as scrap rubber from old tires, to which may be added various other materials such as resins, waxes, pitch, hydrocarbons, bitumen or oils and fillers or fibrous materials such as kaolin, chalk, talc, cotton, wool or asbestos. A layer of China clay may be placed between the rubber compn. layer and the outer yarn covering of the fuse. Cf. C. A. 23, 1752.

Blasting fuses. J. FRITZSCHE. Brit. 295,730, Feb. 15, 1927. Safety blasting fuses are made with a core of powder in which the reactive ingredients (which may be KNO_3 and charcoal, with or without S) are less intimately in contact than in ordinary black gunpowder. The powder may be made without pressing or may contain light inert ingredients such as kieselguhr or MgCO_3 or finely divided pumice or kaolin and may be covered by materials such as paper, metal foil, kaolin, talcum or cement which are non-pervious or but slightly pervious to the gases of combustion. The powder may be treated as described in Brit. 295,406 (preceding abstract). Brit. 295,731 specifies protective waterproofing on fuses comprising rubber substitutes such as factis, linocyn or vulcanized stearin pitch, to which fillers, etc., also may be added.

Blasting fuse manufacture. J. FRITZSCHE. Brit. 295,266, Feb. 7, 1927. An app. is described.

Projectiles with a percussion fuse. O. MATTER. Brit. 295,585, Aug. 11, 1927. Structural features are described of projectiles which may contain a detonating charge of "a metallic salt of nitrogenhydrogen acid" protected by thin metal foil.

Miners' safety lamps and gas detectors. A. G. GULLIFORD and W. MAURICE. Brit. 295,773, May 27, 1927. In lamps with a Pt wire or like device for indicating the presence of CH_4 or similar gases, a variable resistance is included in the circuit of the indicator to enable the amount of CH_4 to be estimated. Various structural details are described.

-DYES AND TEXTILE CHEMISTRY

L. A. OLNEY

Process trends in dyeing, bleaching and finishing. PAUL F. HADDOCK. A. Khipstein & Co. *Cotton* 93, 281-3 (1929).

The transparency of textile fabrics in ultra-violet light. S. R. TROTMAN. *Textile Recorder* 47, No. 550, 63 (1929).—In defining transparency of fabrics, it is important to specify whether the ultra-violet light is transmitted in quantity sufficient to be of therapeutic value or in such minute quantities as to require tests of great delicacy to detect. The first is the important condition from the practical viewpoint. A simple method of testing consists in wrapping a piece of cotton dyed with a dyestuff very sensitive to light in the fabric to be tested, and exposing the wrapped samples to ultra-violet light. Tests carried out using as wrappers coarse wool web, high-grade wool web,

chlorinated wool, over-chlorinated wool, cotton, silk and viscose, cuprammonium, chardonnet and celanese rayons indicate that no ordinary textile fabric, even in a thin layer, transmits any appreciable quantity of ultra-violet light, unless it is loosely knitted. In this case, the rays pass through the interspace. RUBY K. WORNER

Consumers are demanding more durability in textiles. CHARLES F. GOLDTHWAIT Mellon Inst. Industrial Research, Pittsburg, Pa. *Textile World* 75, 1669-70(1929).

RUBY K. WORNER

The finishing industry and its development in the south. HARRY R. STEPHENSON *Cotton* 93, 264-5(1929).

Increasing the tensile strength of artificial silk. S. R. TROTMAN. *Textile Recorder* 47, No. 551, 37(1929).—See C. A. 23, 1755.

RUBY K. WORNER

The chemical analysis of cotton. The action of sodium hydroxide solutions on modified cotton cellulose at the ordinary temperature. CONSTANCE BIRTWELL, DOUGLAS A. CLIBBENS AND ARTHUR GEAKE. Shirley Institute, Didsbury. *J. Textile Inst.* 19, 349-64T(1928).—For studying the relationship between soly. of a given modified cotton and concn. of the solu., a series of tests was carried out on 3 cottons, an oxycellulose of Cu no. 6.7 and 2 hydrocelluloses of Cu no. 2.95 and 2.29, resp. A 1-g. sample was stirred for 1 hr. with 25 cc. NaOH soln. varying in concn. from 0 to 10 N, and the soly. detd. volumetrically. In each case, the max soly. at 15° occurred at about 3 N NaOH, the soly. decreasing rapidly from that point with either increasing or decreasing alkali concn. A much greater soly. of the modified cotton is obtained when it is first treated with more concd. NaOH (6 to 15 N) and the alkali subsequently diluted (1 to 3 N) by adding water to the mixt. The max. soly. at 15° was realized by first steeping the cotton in 10 N and then dilg. the alkali to 2 N (10N-2N treatment). The soly. is not greatly affected by increasing the time of contact of the cotton with either the concd. or the dil. alkali. Temp. plays an important role, particularly between 15 and 25°, the soly. decreasing with rising temp. With loose cotton, shaking is not essential, but with cotton cloth, both shaking and disintegration are necessary. In studying the relationship between the soly. of modified cotton and the extent and nature of the modification, a standard method of extn. with 10N-2N NaOH at 15° was used. For hydrocelluloses, the Cu no. defines the soly., irrespective of whether the hydrocellulose is formed by 20% HCl acting for some days at 20° or by 0.5% H₂SO₄ acting for some hours at 100°. During the early stages of acid attack resulting in Cu no. up to 2 there is little increase in soly., but thereafter the soly. rises rapidly with Cu no. For oxycelluloses, in any one series of oxidized cottons formed by the action of the same oxidizing agent acting under the same conditions for varying times, the soly. is defined by the Cu no.; but for modified cottons produced by different agents or by the same agent acting under different conditions, there is no general relationship between the soly. and the Cu no. Between soly. and fluidity in cuprammonium soln., there exists for modified cottons in general, a close correlation which is independent of the method of modification and is unaffected by boiling the modified material with dil. alkali. The "reducing value" of the alkali-sol. fraction was measured by detg. the amt. of C reduced by 75 cc. alk. soln., and recalcd. the result to the basis of 100 g. dissolved cotton. Comparisons of the Cu nos. of modified cotton and the reducing properties of their alkali-sol. fractions show that with increasing modification of the cotton (Cu no.), the reducing value of the ext. rises rapidly at first but reaches a roughly const. value for Cu nos. above 2. This const. value is dependent on the type of modification being about 4 for hydrocelluloses irrespective of the method of their formation, 8 for oxycelluloses formed with neutral hypochlorite and with K₂Cr₂O₇ in H₂SO₄ soln., 12 for HOCl oxycelluloses and 20 for cotton oxidized with K₂Cr₂O₇ in H₂C₂O₄ soln. Oxycelluloses formed by the action of alk. hypobromite and all modified cotton which have been boiled with alkali have low reducing values and Cu nos. R. E. W.

Foreign matter in cotton fabric. HUGO KAUFFMANN. *Melliands' Textiltech.* 9, 575-7(1928).—The rate of decompn. of NaOCl may be expressed in the following form:

$$\frac{d[\text{OCl}]}{dt} = -K[\text{OCl}]^2$$

The catalytic action of various metal hydroxides is shown by the following values of K, obtained when small quantities were added to 0.05 M NaOCl at 25°: Co, 75; Ni, 51; Cu, 44; Sn, 2.5; and Fe, 0.5. In the pure soln. K = 0.01. The damaging possibilities of MgCl₂ in fabric coming to the bleachery are well-known. A convenient test for Mg in cloth is the blue color produced when a sample is dipped into an alk. soln. of p-nitrobenzenesazoresorcinol, and then into 10% NaOH. F. R. C.

Shaking of cotton warps. RICHARD G. KNOWLAND. *Textile Recorder* 46, No. 549, 63-4(1928).—The importance stressed of uniform conditions as to size, steam, temp.,

speed, etc. throughout the slashing operation in order to obtain uniformity in the amt. of size taken up by the warp and in the percentage of moisture left in it. R. K. W.

A new era for flax. GEORGE A. LOWRY. *Textile Recorder* 47, No. 551, 35-6(1929).—A new machine which threshes and scutches unretted or retted flax in one operation and gives double the yield of fiber previously obtained, together with a new degumming process, simplifies the handling of flax and reduces the production cost of the fiber.

RUBY K. WORNER

Preparing and spinning flax, hemp, jute and tow. CLIFFORD CARTER. *Textile Recorder* 47, No. 550, 37-8(1929).—A general discussion is given of the processes involved.

RUBY K. WORNER

Bleaching of Phormium tenax. P. W. AITKEN. *New Zealand J. Sci. Tech.* 10, 226-40(1928); cf. C. A. 22, 1790.—Sodium hypochlorite, bleaching powder and KMnO_4 are discussed as bleaching agents. As far as can be seen, the result of treatment with these compds. produces permanence of color. Tests show that there is no loss of strength in comparison with paddocked fibers. The greatest danger to strength lies in the use of acid Na hypochlorite, as the risk of chlorinating the fiber is great. R. C. E.

Wool accurately graded by microscopic measurement of diameter. H. B. GORDON. U. S. Testing Co., Inc. *Textile World* 75, 1671-3(1929).—Measurements made on top and raw wool standards prepd. by the U. S. Dept. of Agr. are reported. R. K. W.

The K. B. B. Fugitometer. KLEVIN, BOTTOMLEY & BAIRD, LTD. *Textile Recorder* 47, No. 550, 43(1929).—An illustrated description is given of this app., which has been designed for the rapid testing of fastness to light of dyed materials. The samples undergoing tests are surrounded by an atmosphere of known and const. humidity.

RUBY K. WORNER

2-Aminoanthraquinone from chlorobenzene and phthalic anhydride [vat dyes] (GROGGINS, NEWTON) 10. Substantive dyes derived from 2,7-diaminofluorene (NOVELLI, RUIZ) 10. Clarification of benzine (Fr. pat. 646,721) 22. Solvents and dispersing agents for dyes (Fr. pat. 646,816) 13. Condensation products from *p*-halogenated phenolic compounds and aldehydes [for moth-proofing textile fabrics] (U. S. pat. 1,707,181) 18. Anthraquinone derivatives [intermediates for making dyes] (Brit. pat. 295,943) 10. Dyes (Brit. pat. 295,605) 17.

Deutscher Färberkalender für das Jahr 1929. Wittenberg: A. Ziemsen. 38th Annual ed. Published by Deutsche Färber-Zeitung. 296 pp. M. 5. Reviewed in *Ind. Eng. Chem.* 21, 393(1929).

Dyes. L. B. HOLLIDAY & CO., LTD., and C. SHAW. Brit. 295,506, July 28, 1927. Gray to black vat dyes which are oxidation products of dibenzanthrone similar to those described in Brit. 277,125 (C. A. 22, 2470) are obtained by oxidizing dibenzanthrone (or its low oxidation products obtained with H_2SO_4 and HNO_3 or H_2SO_4 and MnO_2), with H_2SO_4 and salts such as NaClO_2 and KMnO_4 which are capable of reacting with H_2SO_4 to give unstable highly oxygenated acids or peroxides.

Dyes. J. G. KERN (to E. I. duPont de Nemours & Co.). Brit. 295,716, Aug. 19, 1927. Leuco esters of vat dyes are stabilized by treating them with an alkylolamine. The Na salts of the leuco esters may be dissolved in the alkylolamines such as diethanolamine, mono- or tri-ethanolamine, methyldipropanediolamine or the like, or the Na salts may be treated with an org. acid such as HOAc to liberate the acid esters which are then converted into the alkylolamine salts. The alkylolamine may also be added to a printing paste made up with a leuco ester and cotton, silk or wool may be printed with the paste and passed through a bath contg. FeCl_3 , NH_4 persulfate or NaNO_3 and H_2SO_4 .

Dyes. LEOPOLD LASKA and FRITZ WEBER (to Grasselli Dyestuff Corp.). U. S. 1,706,927, March 26. By combining aromatic *o*-hydroxydiazo compds. (such as those from 4-chloro-2-aminophenol, 4-nitro-2-aminophenol, *p*-nitro-*o*-aminosalicylic acid or picraminic acid) with 2,8-dihydroxynaphthalene-6-carboxylic acid mordant dyes are produced which dye wool brownish tints turning to fast brown to black when after-chromed.

Dyes. BRITISH DYESTUFF CORP., LTD., A. DAVIDSON and A. SHEPHERDSON. Brit. 295,770, May 26, 1927. Vat dyes are made by treating a 1-arylaminoanthraquinone-2-carboxylic acid at an elevated temp. in the presence of a solvent of high b. p. with a reagent capable of converting the COOH group into the carboxylic chloride group (this reagent being used in excess) and then treating the intermediate thus obtained

with a chlorinating agent at 160–190° with or without use of a catalyst such as I. Dyes thus prepd. from 1-anilino- and 1- β -naphthylaminoanthraquinone-2-carboxylic acid, by use of SOCl_2 in trichlorobenzene, followed by chlorination without isolation of the intermediate products give pink and orange-brown shades, resp. 1-*p*-toluinoanthraquinone-2-carboxylic acid is also mentioned as a suitable starting material. The intermediate products are probably 3,4-phthaloyl-9-chloroacridines.

Dyes. I. G. FARBENIND. A.-G. Brit. 296,106, Feb. 22, 1927. *N*-dihydro-1,2,1',2'-anthraquinone azine is made by caustic alkali fusion of 2-aminoanthraquinone, with or without use of oxidizing agents, in the presence of a salt of a lower aliphatic acid such as NaOAc together with a salt of an aliphatic acid contg. more than 3 C atoms such as Na amylate or K isobutyrate or an alcoholate or phenolate or a water-sol. compd. of high mol. wt. serving as a wetting agent such as sulfonic acid or bile acid salts.

Dyes. I. G. FARBENIND. A.-G. Brit. 295,289, Aug. 8, 1927. Monoazo dyes giving dyeings fast to kier-boiling and to light are formed either in substance or on the fiber by coupling diazotized 1-amino-3,4-dimethyl-6-halobenzenes with arylides of 2,3-hydroxynaphthoic acid. Several examples are given of dyes giving red to bluish-red dyeings.

Dyes. I. G. FARBENIND. A.-G. Brit. 295,645, May 14, 1927. Diphthalyl acridones are converted into vat dyes by treating them with nitrating agents, such as concd. HNO_3 or a mixt. of HNO_3 and H_2SO_4 . The products may be reduced to the amino derivs. and both the nitro and amino compds. dye cotton from the vat, usually in grayish-blue shades. The amino derivs. may be acylated, yielding gray vat dyes of good fastness. Several examples are given.

Dyes. I. G. FARBENIND. A.-G. Fr. 646,017, Dec. 21, 1927. Insoluble azo dyes giving violet shades are prepd. by coupling diazotized aminocarbazoles or their derivs. not contg. a sulfo group, with 2,3-hydroxynaphthoic arylamides. In examples, cotton is impregnated with a soln. of 2,3-hydroxynaphtho-*o* toluides and developed with 1-aminocarbazole. 2,3-Hydroxynaphthoaniside is coupled with diazotized amino-3,6-dichlorocarbazole. The β -naphthylamide, *p*-phenetide and *p*-aniside of 2,3-hydroxynaphthoic acid may also be used and coupled with diazotized 2-, 3- or 4-aminocarbazoles.

Dyes. I. G. FARBENIND. A.-G. Fr. 646,089, Dec. 22, 1927. Monoazo dyes which give violet to black shades on wool and fast shades on acetate silk are prepd. by coupling the diazo compds. of 4-nitroaniline-2-sulfonic acid, 5-nitro-2-aminobenzyl-sulfonic acid or a sulfonic acid of 4-nitro-1-aminonaphthalene with 4'-hydroxyphenyl-2-aminonaphthalene or its substitution products. In examples the prepn. of the dyes from 5-nitroaniline-2-sulfonic acid and 4'-hydroxyphenyl-2-aminonaphthalene or its 3'-carboxylic acid; 4-nitroaniline-2,5-disulfonic acid, 2-methoxy-4-nitroaniline-6-sulfonic acid or 5-nitro-2-aminobenzyl- ω -sulfonic acid and 4'-hydroxyphenyl-2-aminonaphthalene; 4-nitro-1-aminonaphthalene-5-sulfonic acid or 4-nitro-1-aminonaphthalene-6-sulfonic acid and 4'-hydroxyphenyl-2-aminonaphthalene is described. A list of components and the shades obtained on wool is also given.

Dyes. SOC. ANON. POUR L'IND. CHIM. A BALE. Brit. 295,257, Aug. 4, 1927. Methylaminanthraquinone- ω -sulfonic acids, contg. a further substituent in the methyl group, are made by the action of a bisulfite compd. of an aldehyde contg. more than 1 C atom, or of an aldehyde together with a bisulfite, on primary and secondary aminoanthraquinones. The products are suitable for use in dyeing and printing processes, generally, *e. g.*, for dyeing cotton, silk and cellulose acetate. Examples are given of the condensation of 1-amino-4-hydroxyanthraquinone with NH_4HSO_3 and benzaldehyde and of 1,4,5,8-tetraaminoanthraquinone with NaHSO_3 and benzaldehyde. Furfural, acetaldehyde and crotonaldehyde may also be used with various specified aminoanthraquinone derivs.

Dyes. SOCIÉTÉ ANON. POUR L'INDUSTRIE CHIMIQUE A BALE. Swiss 128,208, May 29, 1926. A stable dye prepn is obtained by intimately mixing a finely powd. almost insol. dye with salts of the sulfonation products of the distn. residu. of benzaldehyde. Examples of the dyes are the azo dye obtained from diazobenzene and 1-phenyl-3-methyl-5-pyrazolone, from diazotized *p*-nitroaniline and cresidine, and the dye from 1-amino-4-hydroxyanthraquinone.

Dyes. SOCIÉTÉ ANON. POUR L'INDUSTRIE CHIMIQUE A BALE. Swiss 128,228, May 7, 1927. A symmetrical Cr- and S-contg. dye is prepd. by treating the Cr compds. of the dye obtained from diazotized 1,2-aminonaphthol-4-sulfonic acid and α -naphthol with S. The new dye colors cotton a wash- and light-fast blue in a Na_2S bath.

Dyes. SOC. ANON. POUR L'IND. CHIM. A BALE. Fr. 646,062, Dec. 22, 1927. Dyes obtained by coupling *o*-hydroxydiazo compds. with 3-methyl-5-pyrazolone are treated with chroming agents, the products being sol. in water and dyeing animal fiber in fast

shades from orange to red. In an example, the dye obtained by coupling nitrated 2-hydroxy-1-diazonaphthalenesulfonic acid with 3-methyl-5-pyrazolone is dissolved in boiling water and Cr_2O_3 is added. In general orange dyes are obtained starting with the following: *o*-aminophenols, *o*-aminophenolsulfonic acid, 4-nitroaminophenol-6-sulfonic acid, 6-nitroaminophenol-4-sulfonic acid, 4-chloroaminophenol-5-sulfonic acid, *o*-aminophenol-4-sulfonamide, 4- and 5-nitroaminophenols, 4-chloroaminophenol, picramic acid, etc.

Azo dye. ERICH FISCHER and CARL E. MÜLLER (to Grasselli Dyestuff Corp.). U. S. 1,706,484, March 26. A monoazo dye dyeing cellulose esters bright intense yellow shades is formed by coupling diazotized *p*-aminoacetanilide with *p*-cresol.

Azo dyes. WERNER ZERWECK (to Grasselli Dyestuff Corp.). U. S. 1,706,946, March 26. Dyes are formed by combining various diazo compds. (not contg. a sulfonic acid group) with derivs. of 2,3-hydroxynaphthoic acid such as may be produced by condensing 2 mol. proportions of 2,3-hydroxynaphthoic acid with aromatic mono- or diamines contg. 1 or 2 triazolic groups or with the related aminotriazolic compds. which may be obtained by oxidizing correspondingly substituted *o*-aminoazo compd. The dyes thus formed produce good lakes and give dyeings which, when variously developed, range from yellowish to black. A large no. of examples are given.

Azo dyes. SOC. ANON. POUR L'IND. CHIM. A BÂLE. Brit. 294,883, July 30, 1927. Azo dyes are produced in substance or on the fiber or other substratum by coupling diazo compds. of aryl or aralkyl ethers of *o*-aminophenols with *o*-arylhydroxy- or *o*-aralkylhydroxyanilides of 2,3-hydroxynaphthoic acid. Several examples are given for producing products suitable for coloring varnishes, dyeing cotton, etc.

Azo dyes from hydroxynaphthodiazine derivatives. WILHELM HERZBERG and HEINRICH OHLENDORF (to Grasselli Dyestuff Corp.). U. S. 1,705,974, March 19. By the combination of components such as diazotized 1-aminobenzene-4-sulfonic acid and the compd. obtained by melting an alkali metal hydroxide with 4,8-disulfo-1,2-naphthophenazine or the like, monoazo dyes are obtained which dye wool and cotton various colors. Several examples are given.

Thiazoles and azo dyes. I. G. FARBERIND. A.-G. Brit. 295,295, March 30, 1927. Amino- or iminothiazoles are prepd. by treating a primary arylamine with a thiocyanate in the presence of a halogen; the arylamine used is one in which the *p*-position to the amino group is either substituted by a univalent radical or occupied in the formation of a ring while the *o* position is free. An *o*-aminothiocyano compd. is probably first formed and may then be converted either by standing or by warming to form the isomeric thiazole product. The products are suitable for use as *intermediates for the manuf. of dyes and pharmaceutical compds.* 2-Amino-6-ethoxybenzothiazole, prepd. from *p*-phenetidine, forms a diazo compd. which couples with resorcinol to form a red, with H-acid to form a blue, and with a 2-naphthol-7-sulfonic acid to form a reddish violet dye. Several other examples are given.

Azo dyes containing chromium. SOCIÉTÉ ANON. POUR L'INDUSTRIE CHIMIQUE A BÂLE. Brit. 295,944, Aug. 19, 1927. By the action of reagents such as Cr fluoride, Cr compds. are obtained from *o*-hydroxyazo dyes obtained by coupling diazotized 5-nitro-2-aminophenol with an *N*-acyl-2-amino-5-naphthol-7-sulfonic acid. A large no. of acyl derivs. are specified as suitable and the Cr compds. formed may be used for dyeing cotton or in coloring nitrocellulose varnishes, etc.

Monoazo dyes. I. G. FARBERIND. A.-G. Brit. 295,237, May 4, 1927. Monoazo dyes giving bluish violet to blue shades on "acetate silk" are formed by coupling diazotized picramide or its homologs with a sulfonic acid of a *N*-aralkyl-, or *N*-alkylaralkyl-aniline or a homolog or substitution product such as *N*-ethyl-*N*-sulfobenzyl-3-toluidine. Other examples also are given. The dyes may be used in a neutral Na_2SO_4 bath or an HOAc bath for dyeing "acetate silk" or in an acid bath for dyeing wool.

Disazo dyes. BRITISH DYESTUFF CORP., LTD., R. BRIGHTMAN and P. CHORLEY. Brit. 296,047, April 22, 1927. Disazo dyes are formed by coupling a tetrazotized 4,4'-diaminodiphenyl méno-, di- or tri-sulfide with 2 mol. proportions of a 2,8-aminonaphthol-sulfonic acid or an *N*-substituted deriv. or with 1 mol. proportion of such an acid or deriv. and 1 mol. proportion of a phenol or amine of the benzene of naphthalene series or a sulfonic, carboxylic or other deriv. The products yield dyeings fast to milling on wool and even dyeings on regenerated cellulose artificial silks. Several examples are given of the production of the dyes and of their use on "viscose silk."

Vat dyes. GEORG KALISCHER and WERNER ZERWECK (to Grasselli Dyestuff Corp.). U. S. 1,705,817, March 19. 1,1'-Dinaphthyl-8,8'-dicarboxylic acid or suitable substitution products which may contain halogen or other univalent substituents are treated with acid condensing agents under "moderate conditions" and the benzo-

benzanthronecarboxylic acids thus formed are further heated with alk. condensing agents and the products so formed are finally subjected to the action of acid condensing agents. The vat dyes thus formed are insol. in water, alkalies and the usual org. solvents, are sol. in concd. H_2SO_4 with a yellow to olive color, and with alkaline hyposulfite form blackish violet colored vats from which cotton is dyed blue to gray shades, fast to washing, Cl and light. Several examples with details of procedure are given. Cf. C. A. 23, 1282.

Vat dyes. MAXIMILIAN P. SCHMIDT and OTTO LIMPACH (to Grasselli Dyestuff Corp.). U. S. 1,706,902, March 26. Condensation of *o*-toluhydroxynaphthocarbazole and isatin-2-anilide forms a dye which gives a yellow vat with hyposulfite dyeing wool and cotton black tints on exposure to the air. 5-Chloroisatin-2-*p*-chloroanilide and like compds. form similar dyes.

Vat dyes. I. G. FARBENIND. A.-G. (Arthur Lüttringhaus, Heinrich Neresheimer and Hans J. Emmer, inventors). Ger. 471,377, Oct. 12, 1926. Vat dyes giving reddish brown shades on cotton are prepd. by treating diphthaloylanthraquinones with N_2H_4 . Examples are given describing the prepn. of dyes from N_2H_4 , H_2O and (1) diphthaloylanthraquinone prepd. by oxidizing isodibenzanthrone and (2) the chlorodiphthaloylanthraquinone prepd. by oxidizing 6,6'-dichloroisodibenzanthrone.

Vat dyes. I. G. FARBENIND. A.-G. (Paul Nawiasky, Hans Jos. Emmer and Alfred Ehrhardt, inventors). Ger. 470,184, Aug. 7, 1924. Ether-like compds are prepd. by reducing vat dyes in neutral soln. with metals, and alkylating the product in the absence of water. Thus, dibenzanthrone, Zn dust, the Me ester of toluenesulfonic acid and NaOH are stirred into trichlorobenzene and heated to boiling. The mixt. is cooled, filtered and washed, and the Zn removed by dil. HCl. The new compd. is crystd. from trichlorobenzene. Cu or other metals can be used instead of Zn. Other examples commence with isodibenzanthrone or its oxidation products.

Vat dye. SOCIÉTÉ ANON. POUR L'INDUSTRIE CHIMIQUE À BALLE. Swiss 128,371, Oct. 20, 1926. Addn. to Swiss 125,480. A new vat dye of the anthraquinone series is prepd. by treating violanthrone simultaneously with sulfonating and oxidizing agents, melting the product with KOH and then treating with a methylating agent. In a blue vat it dyes cotton a fast blue. Cf. C. A. 23, 2042.

Vat dyes of the anthraquinone series. WALTER MIEG (to Grasselli Dyestuff Corp.). U. S. 1,706,933, March 26. A 1-aminoanthraquinone-2-aldehyde is reacted on by an α -halogenanthraquinone compd. such as 1-chloroanthraquinone in the presence of a catalyst, *e. g.*, Cu powder, and of NaOAc or other suitable acid-binding agent. Dyes are obtained which dye cotton brownish yellow shades. Cf. C. A. 23, 525.

Vat dyes of the isodibenzanthrone series. ALOIS ZINKE (to Felice Bensan). U. S. 1,705,953, March 19. Dyes are formed by the action of alkali metal hydroxides while heated in the presence of an org. solvent such as aniline or quinoline on dibenzoyldibromoperylene or other suitable diaroyldihalogenperylene having 2 halogens in the perylene nucleus and with each aroyl group occupying a position peri to one of the halogens and having a free *o*-position. The dyes thus formed dye cotton blue or violet shades.

Indigoid dyes. I. G. FARBENIND. A.-G. Fr. 646,349, Dec. 24, 1927. Indigoid vat dyes of the 2-thionaphthene-2-indoleindigo series which dye the fiber violet are obtained by condensing the derivs. of 3-hydroxy-1-thionaphthene substituted in the ring with active compds. of 7-methylisatin substituted in the 5 (or 4 and 5) position by halogen or CH_3 , and in the 2 position by a halogen or an arylamine, which becomes replaced by the thionaphthene radical. Thus, 5-chloro-7-methylisatin is transformed into the corresponding isatin α -chloride by heating with PCl_5 in PhCl and is added to a soln. of 5-chloro-3-hydroxy-1-thionaphthene and the mixt. heated to 80-90°. The dye produced 5-chloro-2-thionaphthene-5'-chloro-7'-methyl-2'-indoleindigo dyes fiber from the vat fast violet shades. 7-Methyl-5-chloro-1-hydroxythionaphthene is heated in NaOH soln. and condensed with 5-chloro-7-methylisatin-4'-chloro-*o*-toluidide. 5,6,7-Trichlorohydroxythionaphthene is condensed with the 4'-chloro-*o*-toluidide of 5-chloro-7-methylisatin. 4-Methyl-5,7-dichlorohydroxythionaphthene is condensed with 5-chloro-7-methylisatin-4'-chloro-*o*-toluidide. Several other examples are given. Cf. C. A. 23, 1285.

Thioindigo dyes. I. G. FARBENIND. A.-G. Brit. 295,239, May 4, 1927. Products giving clear fast violet shades are obtained by bromination, in the presence of H_2SO_4 , of thioindigo dyes of the 2,2'-indolethionaphthene series having a single alkyl group in the indole nucleus. Examples are given.

Pyrazolone dyes. Soc. ANON. POUR L'IND. CHIM. À BALLE. Fr. 646,001, Dec. 22,

1927. Azo dyes particularly suitable for dyeing cellulose esters are prep'd. by diazotizing nonsulfonated homologs or substitution products of PhNH_2 and coupling with 3-methyl-5-pyrazolone. In examples, *m*-nitro-*p*-toluidine is diazotized and coupled with 3-methyl-5-pyrazolone. The product dyes acetate silk and lacs in fast yellow shades. Diazotized aminoazobenzene is introduced into a soln. of 3-methyl-5-pyrazolone contg. NaOAc . The product dyes cellulose esters and lac orange shades. Safranin MN is diazotized and coupled with 3-methyl-5-pyrazolone. The product may be used to produce violet lacs.

Disazopyrazolone dyes containing a 1,5-dihydroxynaphthalene nucleus. LEON W. GELLER (to National Aniline & Chemical Co.). U. S. 1,706,878, March 26. Disazo dyes are formed by coupling a diazotized aminobenzeneazoarylpyrazolone comp'd. with 1,5-dihydroxynaphthalene or by coupling a diazotized aminobenzeneazo-1,5-dihydroxynaphthalene comp'd. with an arylpyrazolone comp'd. The benzene nucleus in the aminobenzene radical or the aryl nucleus in the pyrazolone radical, or both, may contain substituents such as Cl , CH_3 , COOH , OH , SO_3H or SO_2NH_2 and those of the products contg. an acid radical such as COOH or SO_3H in the form of their Na salts are sol. in water and dye wool in an acid bath yellow to red shades which by after-chroming change to orange to red to brown tints. The products are suitable for the production of lakes and pigments.

Dyes of the phenonaphthosafranin series. J. R. GEIGY A.-G. Swiss 128,137 to 128,170, Feb. 8, 1927. Addns. to Swiss 124,764. These dyes are prep'd. by condensing di- or trisulfonic acids of 3-dialkylisrosinduline with monoaminosulfonic acids. The alkyl radical is usually methyl or ethyl. Among the amino acids mentioned are: 1-amino-5-methyl-4-monomethylaniline-2-sulfonic acid, 1-amino-4-dimethylaniline-2-sulfonic acid, 1-amino-4-ethylbenzylaniline-2-sulfonic acid and 1-amino-4-hydroxy-5-methylbenzene-2-sulfonic acid.

Sulfur dyes. OSKAR SPENGLER and RUDOLF WEIDENHAGEN (to Grasselli Dye-stuff Corp.). U. S. 1,705,840, March 18. S is melted together with 4-benzalamino-4'-hydroxydiphenylamine or other suitable leucoindophenol in which the H of the terminal amino group has been exchanged for an org. radical and which is able to undergo thiazole ring closure on heating with S; the products dye cotton blackish brown tints.

New mordant dyes. DURAND & HUGUENIN AKT.-GES. S. A. Fr. 646,720, Jan. 5, 1928. Mordant dyes are obtained by diazotizing an aminoazo comp'd. of the type $\text{R}'\text{N}=\text{N}-\text{R}^2\text{NH}_2$, in which R' is an aromatic group contg. an OH group *o*- to a COOH group, and R^2 is an aromatic group contg. a sulfonic or COOH group, and treating the diazo comp'd. in an alk. or acid medium at ordinary or raised temp. until its coupling power has disappeared. In examples (1) the aminoazo comp'd. in which R^2 is *p*-nitro-aniline-*o*-sulfonic acid and R' is salicylic acid is reduced and diazotized and stirred with dil. NH_3 until the blue color disappears and the soln. is acidified to ppt. the dyestuff which gives a fast reddish brown when chrome printed on cotton. (2) The diazo comp'd. of (1) is boiled with dil. HCl until a sample does not give a blue color with NH_3 . The product gives a yellower tint than that in (1). (3) The acetyl group of the aminoazo comp'd. in which R^2 is acetyl-*p*-phenylenediaminosulfonic acid and R' is *m*-cresotinic acid, is saponified, and the product diazotized and stirred with dil. NH_3 as in (1). The product yields a redder tint in chrome printing than that in (1). (4) The comp'd. obtained by nitration and reduction of the aminoazo comp'd., in which R^2 is anthranilic acid and R' is salicylic acid, is diazotized and stirred with dil. NH_3 as before. The dyestuff gives a yellower tint than that in (1).

Anthraquinone derivatives. BRITISH DYESTUFFS CORP., LTD. Fr. 645,999, Dec. 8, 1927. 1,4-Dialkyldiaminoanthraquinones are converted into products contg. fewer alkyl groups by treating with concd. H_2SO_4 above 150° , or with H_3BO_3 between 130° and 150° . The products dye acetate silk. In an example, 1,4-dimethyldiaminoanthraquinone is heated with H_2SO_4 (100%) at 180 – 200° , and the product, pptd. by diln. with water, dyes acetate silk bright bluish violet shades.

New anthraquinone derivatives. HEINRICH VON DIESBACH. Swiss 127,926 to 127,930, Sept. 23, 1928. Addns. to Swiss 124,526. In the first two patents, *N*-(hydroxymethyl)benzamide is condensed with 2-hydroxyanthraquinone, giving 1-benzoylamino-methyl-2-hydroxyanthraquinone or *N*-(2-hydroxy-1-anthraquinonylmethyl)phthalimide, according to the proportions, which melt at 250° and 265° , resp., with decompn. In the third patent, bis(hydroxymethyl)urea and 2-hydroxyanthraquinone are condensed to give *s*-bis(2-hydroxyanthraquinonylmethyl)urea, which melts at 250° with decompn. In the last two patents, alizarin is condensed with (hydroxymethyl)trichloroacetamide and bis(hydroxymethyl)urea, resp., giving (trichloroacetamidomethyl)dihydroxyanthraquinone which changes above 200° without melting, and α -(dihydroxyanthraquinonyl-

methyl)- β -hydroxymethylurea which decomposes at 204° without melting. These derivs. can be used in the prepn. of dyes and their intermediate products.

Diphthaloyl anthraquinones. ARTHUR LÜTTRINGHAUS, HEINRICH NERESHEIMER and HANS J. EMMER (to Grasselli Dyestuff Corp.). U. S. 1,706,493, March 26. Derivs. of this type are formed by subjecting an isodibenzanthrone to strong oxidation with chromic acid; they may be used for production of vat dyes and give orange-red vats with alk. hyposulfite soln. and have no affinity to vegetable fibers.

Chlorinated anthanthrones. L. CASSELLA & Co. Ges. Brit. 205,600, Aug. 11, 1927. Anthanthrone is chlorinated in H_2SO_4 contg. a small proportion of water (preferably acid of about 85-95% strength), with or without addn. of a Cl carrier and suitably at a temp. of about 45-50°. By this procedure a dye may be formed similar to that of the first example given in Brit. 260,998 (C. A. 21, 3467).

2,3-Aminonaphthol and its derivatives. I. G. FARBENIND. A. G. Fr. 645,919, Dec. 19, 1927. 2,3-Aminonaphthol or its derivs. substituted in the ring is obtained by submitting the arylsulfonates of 2,3-hydroxynaphthamide or its derivs. to the action of NaOCl or KOCl after the Hofmann reaction and sapon. the arylsulfonate of 2,3-aminonaphthol. Thus, *p*-toluenesulfonate of 2-hydroxy-3-naphthamide (from *p*-toluenesulfonyl chloride and 2,3-hydroxynaphthamide) is mixed with alc. and a soln. of NaOCl is added and the mixt. heated. The product, *p*-toluenesulfonate of 2,3-aminonaphthol, m. 144-145°, is sapon. with NaOH EtOH, giving 2,3-aminonaphthol. Similarly benzenesulfonate of 2-hydroxy-3-naphthamide gives benzenesulfonate of 2-aminonaphthol which is sapon. 6-Bromo-2,3-hydroxynaphthamide, m. 295°, (from 6-bromo-2,3-hydroxynaphthoyl chloride and NH_3) is dissolved in NaOH and heated with *p*-toluenesulfonyl chloride. The *p*-toluenesulfonate of 6-bromo-3-hydroxy-3-naphthamide, m. 185° (not corrected), gives after the Hofmann decompn. *p*-toluenesulfonate of 6-bromo-2,3-aminonaphthol, m. 105° (not corrected), which on sapon. gives 6-bromo-2,3-aminonaphthol, m. 222° (not corrected). The compds. are intermediates for dyes.

Dyes for "acetate silk." ROBERT E. SCHMIDT and ROBERT BERLINER (to Grasselli Dyestuff Corp.). U. S. 1,706,498, March 26. By treating hydroxyanthraquinones with ethylene chloride dark cryst. compds. are obtained which dye "acetate silk" generally red to bluish red shades.

Dyes and intermediates. I. G. FARBENIND. A. G. Brit. 205,593, Aug. 11, 1927. In producing 4-methyl-6-halo-3-hydroxythionaphthene and the corresponding thionaphthene dyes, 2-cyano-3-methyl-5-halo-1-thioglycolic acid is prepd. from 1-methyl-2-amino-5-nitro-5-halobenzene, by way of the corresponding 2-cyano-3-nitro-, 2-cyano-3-amino- and 2-cyano-3-diazonium compds. The diazonium compd. may be converted into the thioglycolic acid by forming the xanthic ester and treating with chloroacetic acid after saponifying or by treating with alkali sulfides, reducing to the mercaptan and finally coupling with chloroacetic acid.

Dyes and intermediates. I. G. FARBENIND. A. G. Brit. 205,604, Aug. 11, 1927. Cyanoaryl- α -thioglycolic acids are hydrolyzed to the corresponding carbamyl- α -thioglycolic acids by treatment with H_2O in alk. soln. and by further treatment with alkali hydroxythionaphthene may be formed. An example is given of the treatment of 2-cyano-5-ethoxybenzene-1-thioglycolic acid.

Dye intermediates. J. R. GEIGY AKT. GES. Fr. 645,867, Dec. 17, 1927. Disulfo-*N*-alkyliserosindulines and their derivs. are prepd. by treating 1-chloro-*N*-alkyliserosindulines in the presence of org. solvents with neutral or acid sulfates and oxidizing the products. In examples, 1-chloro-3-diethyliserosinduline-HCl (from phenyl-2-naphthylamine and nitroso-*m*-chlorodiethylaniline-HCl) reacts in aq. soln. with NaOAc, and the product is boiled in alc. with $NaHSO_3$, and air is afterward passed through, giving 1,6-disulfo-3-diethyliserosinduline. 1-Chloro-3-dimethyliserosinduline-HCl, 1-chloro-3-diethyl-11-methyliserosinduline sulfate and 1-chloro-3-diethyl-13-chloroiserosinduline may also be used. The products are intermediates for naphthosaffranine dyes.

Dye intermediates of the 1,9-anthrathiazole series. RALPH N. LULEK (to E. I. duPont de Nemours & Co.). U. S. 1,706,981, March 26. Compds. such as 1-chloro-anthraquinone-2-carboxylic acid or 1-chloroanthraquinone-2-aldehyde are heated with S, alkali sulfide and NH_3 to form products such as 1,9-anthrathiazole-2-carboxylic acid or 1,9-anthrathiazole-2-aldehyde which may be used as dye intermediates.

Dyeing. SOC. DE PRODUITS CHIM. ET MATIERES COLORANTES DE METZ-SE. Fr. 646,214, May 9, 1927. Pptn. by org. acids of sulfurized products of PhOH and its derivs. used as mordants for vegetable fiber, is prevented by the addn. of protective colloids such as cellulose extracts (sulfite lyes), British gum, gum arabic, gelatin or strong glue.

Dyeing cellulose esters. C. DREYFUS (to British Celanese, Ltd.). Brit. 295,579, Aug. 13, 1927. Materials comprising cellulose esters are colored by vat or sulfur dyes applied as printing pastes prep'd. with strong alkalis and the dyes are subsequently fixed in the usual manner. Solvent or softening agents for the cellulose ester such as ethylene dichloride may be included in the printing pastes, as may also suitable discharge agents such as formaldehydesulfoxylate and a leucotrope if it is desired to produce discharge effects by subsequent steaming. Colored discharge effects may also be obtained by adding a dye unaffected by the discharging agent.

Dyeing cellulose esters, etc. I. G. FARBENIND A.-G. Fr. 646,371, Dec. 27, 1927. Dyes insol. in water obtained by treating alkyl- ω sulfonic acid of primary or secondary aminoazo compds. of their salts with alk. agents are used for dyeing cellulose esters or ethers. In examples, the azo dye from diazobenzene chloride and Na methyl-aniline- ω -sulfonate, is heated to 90° in Na₂CO₃ or NaOH soln. The dye which ppts. is brought into suspension with Turkey red oil, etc., and dyes acetate silk in deep greenish yellow shades. If diazotized 3,4-dichloroaniline is used, an intense golden yellow shade is obtained, and if diazotized *p*-nitroaniline is used, strong orange shades are obtained. The dye from diazotized *p*-nitroaniline and the methyl- ω -sulfonic acid of monomethyl-aniline when treated with NaOH soln. gives a product which dyes acetate silk orange-red.

Dyeing cellulose fabrics. J. C. WATSON. Brit. 295,977, May 18, 1927. Fabrics such as those of cotton, or artificial silks such as viscose, cuprammonium or Chardonnet "silks" are made with the component threads in contrasting colors by treating one set of threads before weaving with a vat dye or deriv. and after weaving treating the fabric with a chemical reagent to dye the pretreated set of threads in a contrasting color to the other set of threads. Various examples are given. Brit. 295,982 specifies treating one or both sets of threads, before weaving, with an arylide of 2,3-hydroxynaphthoic acid or a diacetylacetic arylide and, after weaving, developing the color on the pretreated threads with a diazo compd. Examples are given.

Dyeing regenerated cellulose artificial silk. BRITISH DYESTUFFS CORP., LTD., R. BRIGHTMAN AND P. CHORLEY. Brit. 296,011, April 22, 1927. Dyeing in level shades is effected with the dyes obtained by coupling a tetrazotized 4,4'-diaminodiphenyl mono-, di-, or tri sulfite with 2 mol. proportions of an ammonaphtholsulfonic acid or a *N*-substituted deriv. of such an acid or with 1 mol. proportion of such an acid or deriv. and 1 mol. proportion of another coupling component. Several examples are given.

Dyeing, rinsing and other treatments of textile materials with liquids. GEORGE W. STEIGER. U. S. 1,706,827, March 26. The liquid used in several successive baths is caused to flow in alternately upward and downward direction by the action of intermittent vacuum. An app. is described.

Printing colors. I. G. FARBENIND A.-G. Fr. 646,372, Dec. 27, 1927. Flour of horse-chestnuts, preferably freed from saponin, is made into a starch paste and used as a thickening agent for printing colors. It may be mixed with other flour or starch or esters of higher fatty acids or resinic acids and alk. salts.

Color-printing paste. JEAN G. KERN and CHARLES J. SALA (to E. I. du Pont de Nemours & Co.) U. S. 1,705,818, March 19. A vat dye paste such as that formed in making Pensol blue GD is used with glycerol and diethanolamine, to form a paste mixt. suitable for producing bright uniform prints free from speckiness.

Different tints on paper. PACIFIC NORTHWEST PAPER MILLS. Brit. 295,778, May 30, 1927. A plurality of different tints from a single dye are produced on paper by passing it through a dye bath, submitting different portions of the paper to different degrees of pressure, again passing the paper through the dye and finally wringing it. Brit. 295,779 describes an app. for carrying out this process.

Apparatus for dyeing cones of yarn. LOUIS B. HASHPOCK (to Eclipse Textile Devices, Inc.). U. S. 1,705,761, March 19. U. S. 1,705,762 relates to a holder for yarn cones, and U. S. 1,705,763 specifies a special form of injector needle suitable for use in dyeing.

Perforated yarn spool for use in dyeing, bleaching, etc. GEORGE W. STEIGER. U. S. 1,706,826, March 26. Structural details.

Apparatus for continuous drying of warps of artificial silk, silk and schappe silk, etc. MASCHINENFABRIK RÜTI VORM. C. HONIGGER. Fr. 253,331, Aug. 11, 1927.

Roller, tank and spraying apparatus for dyeing fabrics. C. HACKENBROICH and C. D. FRANGOPULO. Brit. 295,569, Aug. 13, 1927. Various structural details are specified.

Device for holding fabrics while boiling, dyeing or delustering, etc. H. PLATT, N. C. SHANE and C. DREYFUS (to British Celanese, Ltd.) Brit. 295,283, Aug. 8, 1927.

Designs on fabrics of cellulose derivatives, etc. C. DREYFUS (to British Celanese,

Ltd.). Brit. 295,582, Aug. 13, 1927. A fabric comprising substances such as cellulose formate, acetate, propionate or butyrate or methyl or ethyl cellulose, animal fibers such as silk or wool, or mixts. of these, is provided with a design in cellulose. This may be produced by printing with viscose or cuprammonium cellulose and then converting the design into cellulose. The material may be subsequently dyed with dyes having selectively different effects on different portions of the material. Substances such as gelatin or casein also may be used for printing designs and if desired may be removed from the fabric after dyeing. Cf. C. A. 23, 289.

Coloring skins, furs, etc. I. G. FARBERIND. A.-G. Fr. 646,944, Jan. 10, 1928. Multicolor effects are produced on skins, furs, etc., by damping certain parts of the article with an alk. soln. or suspension, removing excess alkali by washing the article in water and dyeing with vat dyes.

Textile threads. JEAN BOVEUX. Fr. 646,184, May 5, 1927. Threads particularly of natural or artificial silk are immersed before or after dyeing in a bath containing rubber, mastic and (or) spermaceti dissolved in benzine or other volatile solvent, whereby the adherence of the fibers is increased.

Mercerizing yarns and fabrics. SILVER SPRINGS BLEACHING & DYEING CO., LTD. AND A. J. HALL. Brit. 295,488, July 9, 1927. Yarns and fabrics of cotton, linen or other material containing desulfurized "viscose silk" are mercerized with KOH (suitably of a strength of 60° Tw. at 30°) and may be stretched, washed with hot or cold water, passed through dil. H_2SO_4 and washed and dried; the process up to acidification may be performed in 80 sec.

Finishing fabrics with designs. H. LIVSKY, G. E. HOLDEN AND J. AND J. M. WORRALL, LTD. Brit. 295,203, March 15, 1928. A design is printed on a pile fabric with a strong oxidizing agent and the fabric is then singed to burn away the pile on the treated portions.

Fabric for use in aircraft manufacture. ISADORE M. JACOBSON and STAFF TRUSCOTT. U. S. 1,706,294, March 19. Fabrics are treated with a mixt. of regenerated cellulose and rubber dispersed in org. solvents such as benzene. U. S. 1,706,295 specifies a gas-retaining fabric such as mercerized cotton with a covering consisting of the solute from aq. soln. of a sol. salt of cellulose with glycolic acid or derivs. of such compds.

Apparatus for treating fabrics with liquids. GEORGE HANDBERLIN. U. S. 1,706,901, March 26.

Protecting textile materials against insects. I. G. FARBERIND. A.-G. Brit. 295,742, May 18, 1927. Wool, fur, textile materials, etc., are protected from moths or other insects by treatment with tri-K difluorodisulfate, mono-K monofluorophosphate, the addition product of the Na salt of *p*-toluenesulfonic acid and HF or K₂ fluoride or similar compds. to which other compds. such as org. or inorg. acids or salt also may be added. Several examples are given.

Moth-proof fabrics. I. G. FARBERIND. A.-G. Fr. 646,479, Dec. 28, 1927. Wool, fur, etc., is protected against moths by a soln. of salts having the formula MF(HF)_n in which M stands for a metal. Examples are KF(HF), KF(HF)₂, NaF(HF), NH₄F, HF.

Loading silk. R. CLAVEL. Brit. 296,017, Aug. 23, 1927. Silk in hanks is loaded by a continuous process in which the sep. stages are not interrupted by washing, acidification or neutralization. The loading, *e. g.*, by $SnCl_4$, is effected in the presence of acids or acid salts such as formic acid and phosphate, and the silk may also be treated with Na silicate. An app. is described, the pipes and treating vessels of which may be lined with acid-resisting material such as rubber. Brit. 296,018 also relates to similar process and app. Cf. C. A. 23, 719.

Acetate silk. SOC. POUR LA FABRICATION DE LA SOIE "RHODIASETA." Fr. 646,719, Jan. 5, 1928. The luster is restored to acetate silk by bringing the wetted fabric in contact with a surface heated to 125-170°, under a moderate pressure, preferably 0.3 to 0.5 kg. per sq. cm. The fabric may be wetted with water containing wetting agents such as soap, sol. oil or emulsions of fatty substances, or solns. of $CaCl_2$, $MgCl_2$ or $LiCl$.

Machines for sizing artificial silk or other textiles. BURGESS LEONARD & CO., LTD., and WILLIAM B. CROMPTON. Fr. 646,096, Dec. 23, 1927.

Hollow artificial fibers. ALMA SOC. ANON. Ger. 471,458, Feb. 19, 1928. See Brit. 214,197 (C. A. 18, 2610).

De-lustering artificial silk fibers. OSCAR F. MULLER (to Nyanza Color & Chemical Co.). U. S. 1,705,490, March 19. Artificial silk fibers are treated with an emulsion of olive-oil soap, glue and paraffin, the emulsifying liquid is removed and the material is treated with a bath containing infusorial earth in suspension.

Restoring luster of de-lustered mercerized cotton. CHEMISCHE FABRIK VORM

SANDOZ. Brit. 295,936, Aug. 20, 1927. Material which has been delustered by the "immunizing effect" of treatment with aromatic carboxylic and sulfonic chlorides as described in Brit. 195,619 (*C. A.* 17, 3613) has its luster restored by treatment with steam (preferably under pressure). The steaming increases the resistance of the material to substantive dyes and may be effected while the material is under tension if desired.

Cottonizing fibers such as flax or hemp. BRUNO POSSANNER VON EHRENTAL and KARL SCHOLZ. Ger. 471,103, Nov. 9, 1924. The fibers are held between endless perforated bands which convey them continuously over a series of rollers placed in and above a bath containing the treating liquid. The liquid is circulated by withdrawing it from the bath and introducing it again through nozzles placed closely against the conveying bands.

• **Apparatus for determining the moisture content of wool or other fibrous materials by regulated drying and weighing.** ROYLES, LTD., C. WILSON and E. H. TOWNEND. Brit. 296,157, June 25, 1927.

Scouring apparatus for washing fabrics of wool or wool mixtures. FERNANDO C. PLANELL. U. S. 1,706,349, March 19.

"Dry cleaning" apparatus with an air circulating system provided with a still and condenser. E. W. MISHAW. Brit. 295,548, Jan. 20, 1928. Structural features.

Securing looped pile material to fabric backings by use of vulcanized rubber coatings. P. S. SMITH (to Oryx Fabrics Corp.). Brit. 295,323, Aug. 9, 1927. An app. and various mech. details of operation are described.

26—PAINTS, VARNISHES AND RESINS

A. H. SABIN

Determination of wood oil in oil paints. VON REHNITZ. *Farben.-Ztg.* 34, 266-8 (1928).—Marcusson's method (*C. A.* 20, 2757) for the detn. of wood oil, depending on its polymerization with I to a solid mass, gives results about 10% low. In paints (without thinners) the extn. of linseed oil with chloroform is difficult and results are frequently high. A better approximation to the truth is obtained if the ascertained value is multiplied by the I value of the oil under test, and the product divided by the average of the I values of the boiled and unboiled oils. Small quantities of turpentine oil greatly hinder the polymerization of wood oil and should be removed by shaking with 90% alc. Marcusson's method is indirect since the wood oil is detd. as the difference between the original oil and the extd. linseed oil. The polymerized wood oil can, however, be saponified with 0.5 N alc. potash, the fatty acid pptd. with BaCl_2 and the excess alkali titrated with HCl. This method is described. Comparative tests between it and gravimetric analysis of pure wood oil and mixts. with linseed oil show good agreement. B. C. A.

(Casein-oil) emulsion vehicles. HANS WAGNER and JOSEF KESSELRING. *Farben.-Ztg.* 34, 947-54 (1929).—Casein is usually dispersed in water with KOH, soda, borax or ammonia. The consistencies of such systems range from thin sols to rigid gels. KOH produces the most viscous systems. The m. ps. and viscosities of the dispersions pass through a min. at neutrality. Gels prepd. with soda eventually exhibit syneresis. The effect of disinfectants on the consistency was slight. Ca caseinate prepd. from casein and $\text{Ca}(\text{OH})_2$ is completely insol. in water if not more than twice the stoichiometric proportions of $\text{Ca}(\text{OH})_2$ is taken, but the product resulting from the reaction of alkali caseinate and $\text{Ca}(\text{OH})_2$ tends to be peptized by the residual alkali. Usually casein-oil emulsions are of the oil-in-water type. During drying of films prepd. from such emulsions the oil seps. in drops, followed, if enough oil be present by coalescence (illustrated by photomicrographs). Neutral systems are the most rapid dryers. Linseed oil emulsions film well more in water and adhere less firmly to glass than do those containing oil. The presence of pigment tends towards smaller drops; the properties of some commercial emulsions are tabulated. G. G. SWARD

Emulsion vehicles. FRIEDRICH WAGNER. *Farbe u. Lack.* 1929, 67.—The expts. of Wagner and Kesselring (cf. preceding abstract) were not comparable to actual painting practice and therefore have no significance in paint technology. G. G. SWARD

Specific gravity and viscosity of varnishes, paints, etc. H. L. HAZELTINE. *Instruments* 2, 65-8 (1929).—Orifice type viscometers are not suitable for use with paints or varnishes, as partial closure of the orifice may occur with oxidation or drying of the material. Stormer and MacMichael viscometers are approved for paints and varnishes; a brief description is given of the use of the Stormer instrument. The viscosity of the

material depends on the nature of the solvent and of the non-volatile constituents, and on the percentage of base or useful material; therefore, viscosity measurements on different materials are not on a strictly comparable basis. C. Z. ROSECRANS

Plasticizers in the plastic and lacquer field. T. S. CARSWELL. *Plastics* 5, 80-1, 93(1929).—A satisfactory plasticizer for cellulose esters should meet as nearly as possible the following requirements: (1) have good soly. for the cellulose ester; (2) have little inflammability; (3) be colorless and odorless and not change color on exposure to light; (4) be stable against the action of cold, moderate heat, or moisture; (5) have no tendency to crystallize or sep. out of the film; (6) have a high b. p. and be practically non-volatile at ordinary temps.; and (7) have low acidity to prevent hydrolysis to cellulose ester. In general plasticizers suitable for nitrocellulose are not suitable for acetyl cellulose. There appears to be no relationship between the phys. properties of a chem. compd. and its value as a plasticizer. There are very few good plasticizers with a m. p. over 100°. In the toluenesulfonamide group, the presence of a Ph substituent in the sulfonamide-N decreases the light fastness, while an alkyl group increases it. Several common plasticizers are mentioned. W. H. BOYSTON

Ventilation of japanning ovens. WM. J. MISKELLA. *Fuels & Furnaces* 7, 415-8, 428(1929). E. H.

Report of committee D-17 on naval stores. F. P. VEITCH, et al. *Proc. Am. Soc. Testing Materials* 28, Pt. 1, 602-7(1928). The m. p. and viscosity of rosin were detd. on 4 samples by ring and ball and by capillary methods. In the capillary method the softening point is the temp. at which the rosin in the capillary tube begins to coalesce, and the m. p. is the temp. at which the rosin becomes transparent. The methods are described in 2 appendices. W. H. BOYSTON

The ultra-violet detector as an aid in distinguishing genuine amber from its imitations. I. G. KOSTKA. *Chem. Ztg* 53, 117-8(1929). Various kinds of genuine and artificial amber were examd. with the ultra-violet rays produced by a quartz lamp transmitting rays of wave length $\lambda = 440 - 280\mu$, the rays emanating from a H. lamp. Natural amber is strongly fluorescent, giving a greenish white light, but taking on a more yellow or bluish color in certain specimens. Non-transparent varieties appear to be bathed in a white light with bluish or greenish tints. Phenol formaldehyde plastic give no fluorescence, urtra-formaldehyde products show blue, casem derivatives appear bluish to bluish white; celluloid and celloid become bright blue. Differences in the appearances of native clear and of compressed specimens made from smaller pieces pressed together at a higher temp. are ascribed to variations in structure rather than to differences in compn. II. *Ibid* 138-9. The sp. gr. of amber is 1.05-1.06, while that of resite (artificial resin made from HCHO and C₂H₅OH) is 1.25-1.27 and that of other artificial resins is even higher. Hardness, n , behavior towards polarized light etc. offer no means of distinguishing genuine from artificial amber. The ultra-violet detector is undoubtedly the best test to apply. W. C. LEECH

The composition of oleoresin and colophony from Pinus silvestris as compared with that from other conifers and those from foreign products. V. SHKATULOV. *Zhurn. Belorusskoi Gosudarst. Akad. Sel'skogo Khozyaystva* (Memors. Belorussian State Acad. Agr.), 4, 113-27(1927). S. reports the analyses of oleoresin and colophony supplementing his previous work. (Cf. C. A. 2, 1714). He found that a product was obtained from fresh oleoresin which, contrary to former observations, was dextro-rotatory, $[\alpha]_D^{20} +5.26^\circ$. From this he isolated by the usual methods the 4 isomers α , β , γ , and δ . The acid no. in the untreated portion was 13.1% as compared with 17.2% from a French sample. The amt. of Ag found in the Ag salt formed was 24.46%. A comprehensive French summary is appended. J. L. LEECH

Alkyd resins as film-forming materials. R. H. KIENLE AND C. J. JOHNSON. *Ind. Eng. Chem.* 21, 349-52(1929). Alkyd resins include all complexes resulting primarily from the interreaction of a polyhydric alc. and polybasic acid. Alkyd resins are classed as: heat-non-convertible, heat-convertible, and oxygen-convertible. The prepn. and general properties of these resins are outlined. Two types of soln. can be prepd. with alkyd resins as base, i. e., baking and air-drying. W. H. BOYSTON

Ultra-violet light transmission characteristics of some synthetic resins. D. L. GAMBLE AND G. F. A. STUTZ. *Ind. Eng. Chem.* 21, 330-3(1929).—A comparative study was made in which the ultra-violet absorption characteristics of a no. of synthetic resins have been detd. and the resins classified according to these characteristics. Transmission measurements were made on unexposed resin and after exposure to ultra-violet light for 48 hrs. The degree of yellowing accompanying such exposure was detd. and the tabulated data correlated with results of exposure tests should give indications as to the ultra-violet absorption characteristics most desirable in a resin. W. H. BOYSTON

Formation of resin in conifers (PIGULEVSKII, RISKINA) 17. The effect of electrolytes on organic iso-colloidal systems (AUER) 2. Azo dyes containing Cr [for coloring nitro-cellulose varnishes] (Brit. pat. 295,944) 25. Apparatus for drying paints in currents of heated air (U. S. pat. 1,706,993) 1. Air circulating system for drying paints, varnishes, etc., in a tunnel kiln (U. S. pat. 1,706,554) 1. Esters of polycarboxylic acids [for use as plasticizer in lacquers] (U. S. pat. 1,706,639) 10. Azo dyes (Brit. pat. 294,883) 25.

Lead sulfate pigment. SYDNEY W. KENDALL. U. S. 1,706,301, March 19. Sulfide ore such as galena is heated in a reducing atm. to vaporize the sulfide without oxidation, the vapors are oxidized to sulfate and then immediately chilled by atomized liquid such as water injected in limited quantity so that it becomes completely vaporized, and sprayed with reagents such as ultramarine blue capable of modifying the character of the sulfate, finally cooled and sepd. by filtration.

Fire-resisting paint. NEVIL M. HOPKINS (to Burnot Fireproofing Products, Inc.). U. S. 1,706,733, March 26. A paint is formed with oil and pigments together with sufficient borax, in the form of an impalpable powder, to form an O-excluding glaze when exposed to heat on articles such as wood to which the paint may be applied, and contg. also a flux-promoting agent such as Pb borate or Zn borate which assists in the formation of the O-excluding glaze.

Paint, varnish, etc. GEORGES WISSNER. Fr. 646,195, May 6, 1927. Substances whose mols. are more active than the solvent of the paint, etc., and which do not become oxidized, are added to paint, etc., to form on the surface treated a thin layer to which the film of paint becomes united. Suitable substances are palmitic and stearic acids (e. g., 0.25-1%).

Colored varnishes. I. G. FARDENIND, A. G. Brit. 295,941, Aug. 19, 1927. Alc. solns. of natural or artificial resins are colored, fast to light, by use of basic dyes such as triarylmethane dyes together with a small proportion of a strong org. or inorg. acid, a salt of acid reaction or a nitrate sol. in the varnish, e. g., trichloroacetic, perchloric, or nitrous acids, HCl, H₂SO₄ or HNO₃, AlCl₃, FeCl₃, CuCl₂, bisulfates, or nitrates of Ca, Sr, Bi, Th, U and Co.

Synthetic resin varnishes, etc. BAKELITE GES. Brit. 295,335, Aug. 9, 1927. Phenolaldehyde resins in the "B state" are dissolved in solvents such as cyclic ketones (e. g. cyclohexanone) or cyclohexanol or other cyclic alcs. or their esters, furfural, hydrated phenols and naphthalenes, phenol esters and their mixts. such as with benzenoid hydrocarbons, gasoline, tetrahydrobenzene, benzene bromide, chlorinated hydrocarbons, linseed oil, poppy seed oil, wood oil, stand oil, etc. Small quantities of catalysts such as NH₃, org. bases, (CH₃)₃N₄, nitrophenols or nitrocresols, phenylaminocresol, picric acid, styphnic acid, bicamide, triutrophenatole, picramic and isopicramic acids, fillers and coloring substances, etc., also may be added to varnishes or lacquers. Similar compns. also may be used for impregnating, as cements or for molding, making grinding disks, etc.

Synthetic resins. BAKELITE CORP. Brit. 295,442, May 13, 1927. Dihydroxydiphenylethane (or a phenolic mixt. which contains it) is condensed by heating (suitably at 180-200°) with polymerized CH₂O, (CH₃)₃N₄ or other CH₂-contg. hardening agent. The products are generally similar to those of the phenol-CH₂O type.

Synthetic resins. LA BAKELITE and HENRI STEINMANN. Fr. 646,529, Dec. 29, 1927. Synthetic resins, such as "bakelite," are polymerized not by heat but by submitting them to long wave length radiations which extend into the ultra-violet region, obtained, e. g., from Hg vapor lamps.

Synthetic resin. EMIL E. NOVOTNY and CHARLES J. ROMIEUX (to John S. Stokes). U. S. 1,705,494, March 19. Phenol is boiled with a polyhydric alc. such as glycerol in the presence of H₂SO₄ in small quantity, and water is removed from the zone of the reaction as fast as it is formed.

Synthetic resin. EMIL E. NOVOTNY and DONALD S. KENDALL (to John S. Stokes). U. S. 1,705,495, March 19. In forming a potentially reactive synthetic resin, phenol and furfural are heated together after admixture, in such proportions (suitably 100 and 75 parts, resp.) as to insure substantially complete combination, in the presence of a basic catalyst such as K₂CO₃, 2 parts. Water evolved during the reaction is removed. U. S. 1,075,496 specifies the use of a furane deriv. such as furfuramide as a hardening agent to accelerate the conversion of resinous products such as those of the phenol-furfural type from a fusible to an infusible state.

Synthetic resins. I. G. FARDENIND, A.-G. (ARTHUR MOSS, inventor). Oct. 210,010, Sept. 30, 1927. Hard resinous products are prepd. by treating a phenol-formaldehyde

condensation product with a halogen-fatty acid, converting the product into its NH_4 salt, and heating this at a temp. above 100° . The NH_4 salts are sol. in H_2O and the solns. can be used as *lacquers* or mixed with fillers and molded. The final products are insol. and infusible. In an example, an alk. soln. of a condensation product from technical cresol and CH_2O is treated with ClCH_2COOH . The resin acid is pptd. with HCl , washed, and treated with NH_4OH . Cf. C. A. 23, 1764.

Industrial articles from synthetic resins. COMPAGNIE FRANÇAISE POUR L'EXPLOITATION DES PROCÉDÉS THOMSON-HOUSTON. Fr. 646,424, Dec. 28, 1927. Tiles, etc., of mineral compn. including asbestos are coated with a resin consisting of a polyhydric alc. and a polybasic acid, such as glycerol and phthalic anhydride. The resin may be colored with a dye and applied as a powder or by dipping, spraying or painting and afterward baked.

Phenol-furfural synthetic resin. EMIL E. NOVOTNY and DONALD S. KENDALL (to John S. Stokes). U. S. 1,705,493, March 19. Phenol and furfural are heated together under such conditions (suitably at a temp. of about 350° or lower) that substantially all the materials enter into chem. combination and form a sol., fusible condensation product, which by further heating is converted into an infusible-insol. form.

Resins; paper. DANIEL GARDNER. Fr. 646,170, Apr. 30, 1927. See Brit 289,774 (C. A. 23, 1000).

Coumarone-indene resins. RALPH L. EMERY (to Neville Chemical Co.). U. S. 1,705,857, March 19. A coal tar distillate is prepd. in which the content of coumarone or indene, or both, constitutes as much as 80% of the whole; this distillate is polymerized with the production of incidental ppts., the polymerized material is dild. with petroleum benzene in which the ppts. are insol., the ppts. are removed, and the dissolved resin is sep'd.

Artificial resinous materials. H. W. MATHESON and F. W. SKIRROW (to Canadian Electro Products Co., Ltd.). Brit. 295,322, Aug. 9, 1927. Products varying in consistency from tough rubber-like masses to soft sticky products are obtained by reaction of vinyl esters or halides such as vinyl acetate or formate with aldehydes such as acetaldehyde or CH_2O . The reaction may be effected at room temps. to temps. of 100° or higher and with or without increased pressure. Cf. C. A. 22, 3056.

27—FATS, FATTY OILS, WAXES AND SOAPS

E. SCHERUBEL

Recent advances in our knowledge of the structure of the more common fats. T. P. HILDITCH. *Chemistry & Industry* 48, 212-6 (1929). E. H.

Component glycerides of cacao butter. COLIN H. LEA. *J. Soc. Chem. Ind.* 48, 41-6T (1929).—Oxidation of cacao butter by means of KMnO_4 in acetone shows only 2.5% of satd. glycerides; these are apparently mixed palmitic—stearic compds., the proportion of palmitic to stearic acid being 2:1. From this proportion of fully satd. glycerides, their equiv. and that of the whole fat, and the amt. of unsatd. acid in the latter, it follows that the content of mono-oleo-disatd. glycerides must lie between 75 and 85% while the dioleo-mono-satd. glycerides cannot exceed 24.5% or that of olein 12.5%. The mol. ratio of satd. acids in mixed glycerides is 1.4:1. These calculations are supported by study of the monoazela-glycerides in the oxidation products. Fractional sepn. of the Li salts of the latter has indicated that over 70% of the original fat is accounted for in the form of monoazela-glycerides by analysis of these fractions. Isolation of these glycerides as Na salts has accounted for about 53% of the original fat. Little has been forthcoming as to the compn. of the dioleo-glycerides, but, from the ascertained distribution of the satd. acids, it is to be inferred that dioleostearin is present, probably in amt. greater than that of dioleopalmitin. The content of triolein can hardly exceed 4%. A general est. of the compn. of cacao is: satd. glycerides (mainly mixed palmitostearins) 2.5%, mono-oleo-disatd. glycerides (oleodistearins 10%, oleopalmitostearins, at least 50-60%) 77%, dioleo-mono-satd. glycerides (mainly dioleostearins) 16%, triolein (?) 4%. E. SCHERUBEL

The component glycerides of a mutton tallow. G. COLLIN, T. P. HILDITCH and C. H. LEA. *J. Soc. Chem. Ind.* 48, 46-50T (1929).—A sample of mutton tallow, the fatty acids of which consisted of 4.6% myristic, 24.6% palmitic, 30.5% stearic, 36% oleic and 4.3% linoleic, was oxidized by KMnO_4 in CH_2Cl_2 and the products of complete oxidation were exam'd. There was 26% of satd. glycerides, consisting of 6.1% myristic, 39.2% palmitic and 43.7% stearic acid. Fractional crystn. of the satd. glycerides

showed that a complex mixt. was present; evidence of tristearin, palmitodistearin, and dipalmitostearin was obtained. The proportion of satd. and unsatd. acids in the mixed satd.-unsatd. part of the fat was estd. (1) from the % of satd. glycerides, the mean equivs. of the latter and of the original tallow, and the amt. of unsatd. acids present in the tallow, and (2) from the compn. of the fatty acids present in the mixed satd.-unsatd. glycerides (detd. by the difference between that of the satd. glycerides and that of the whole fat). The same value was obtained by each method, 0.9 equiv. of satd. acids per equiv. of unsatd. acid. The following are limiting values for the various classes of glycerides present: fully satd. 26%, mono-unsatd.-di-satd. 30 to 52%, di-unsatd.-mono-satd. 44%, tri-unsatd. 0 to 22%. Examn. of the acidic products of oxidation by fractional crystn. did not give as good results as with cacao butter. The evidence obtained shows that there is probably a fairly large amt. of di-unsatd. glycerides present, and, correspondingly, a relatively small % of triolein.

E. SCHERUBEL

Attempts toward a determination of the higher unsaturated fatty acids. H. H. ESCHER. Pharmacol. Inst. Univ. Zurich. *Helv. Chim. Acta* 12, 27-49(1929).—Illustr. The difficulties are discussed of sepg. satd. from unsatd. fatty acids and the individual acids from each other. Expts. are then described leading to a quant. sepn. of the higher unsatd. acids by bromination, conversion into acid chlorides, condensation by *p*-aminoazobenzene and final fractional crystn. *Method*—2.10 g. of the oil are sapond. with a 13-18% soln. of KOH in MeOH at 30-40° for 1-3 days. The free alkali is titrated back against phenolphthalein at -10°, yielding the sapon. no.; titration is continued in dil. aq. soln. against methyl orange, furnishing the fatty acid no. The unsaponifiable may then be detd. by extn. The fatty acids are shaken out, washed, concd. at 30-40° and brought to const. wt. at 1-12 mm. vacuum over P₂O₅, giving the wt. of the fatty acids. The acids are brominated with an excess of a titrated 2/N soln. of dry Br, free from HBr, in dry CCl₄ at -15° in the dark. The excess Br is titrated back with a 50% Na₂S₂O₃ soln., with addn. of much H₂O and an excess of KI; this furnishes the Br no. The substituted HBr is detd. by the Mellinkey method with KIO₃, either gravimetrically by AgNO₃ in the presence of AcOH or volumetrically with 0.1 N NaOH and tropaeolin 0.0, furnishing the HBr no. The brominated acids are shaken out, washed, concd. as before at 30-40°, 1-10 mm. vacuum and P₂O₅, furnishing the Br absorption value. The "solid" Br acids are isolated by 2 pptns. with petroleum ether; since they crystallize well, they may be sepd. by fractional crystn., when their Br content furnishes the tetra- and hexabromide no. The mother liquor, contg. the "liquid" Br acids plus some solid satd. and unsatd. acids, is converted into acid chlorides with 15 times their mol. amt. of thionyl chloride at 90°; the excess of thionyl chloride is removed by low-boiling solvents and vacuum, this furnishes the acid chloride no. The acid chlorides are mixed at -15° with double the amt. of *p*-aminoazobenzene in some dry solvent for polymerization; after removal of the solvent by vacuum distn. the product is washed with 40% alc. contg. some HCl and is dried, yielding solid aminoazo compds, which are finally sepd. by fractional crystn. from MeOH contg. increasing amts. of H₂O; this yields the Br acids. Some of the properties of the *p*-aminoazo compds. are tabulated:

<i>p</i> -Aminoazo compd.	M. P.	Yield	% N		% Br	
			found	calcd	found	calcd.
Palmitic acid	98%	121.5-122.5	9.64	9.64
Stearic acid	98%	123-124	9.05	9.04
Oleic acid	97%	About 93-94	9.44	9.10
Elaidinic acid	97%	About 111.5-112.5	9.17	9.10
Dibromooleic acid	98%	About 90-91.5	6.85	6.76	25.31	25.74
Dibromoclaudinic acid	95%	About 131-132	6.58	6.76	25.34	25.74
Tetrabromolinolic acid	87.5%	About 137-138	5.60	5.40	40.52	41.03

P. ESCHER

Remarks on the distillation of the higher unsaturated fatty acids. H. H. ESCHER. Pharmacol. Inst. Univ. Zurich. *Helv. Chim. Acta* 12, 99-102(1929).—A review of the literature leads to the conclusion that the naturally occurring unsatd. fatty acids, especially oleic acid, are more sensitive to temp. than is commonly accepted and a rearrangement within the mol. is possible during heating. Holde and Gorgas' method (C. A. 21, 732) of prepg. oleic acid without heating from crystd. dibromooleic acid by debromination appears to be the only method yielding pure oleic acid.

P. ESCHER

Application of the hydrogen value to unsaturated fatty acids. H. I. WATERMAN, S. H. BERTRAM AND H. A. VAN WAGEN. *J. Soc. Chem. Ind.* 48, 50-51T(1929).—The method for the detn. of the H value described in *J. S. C. I.* 47, 303T, 1928, has been applied to elaidic, linoleic and stearolic acids. The observations with elaidic acid are

considered as standard measurements. It has been shown that $\Delta^{9,12}$ linoleic acid contains 2 double linkings. This fact proves that the abnormal behavior of thiocyanogen toward linoleic acid cannot be explained by the hypothesis of a triple and a double linking in this acid. The linoleic acid and the stearolic acid both consumed the theoretical quantity of H, viz. 2 mols. of H per mol. of the unsatd. fatty acid. The hydrogenation product in each of the 3 detns. was pure stearic acid. E. SCHERUBEL.

Conversion of the higher fatty acids into their barium soaps. H. H. ESCHER. Pharmacol. Inst. Univ. Zurich. *Helv. Chim. Acta*, 12, 103-5(1929).—By using MeOH in place of H_2O as a solvent for $Ba(OH)_2$, it is possible to titrate sharply stearic, palmitic, oleic and even dibromooleic and tetrabromolinolic acid in alc., ether, $CHCl_3$, CCl_4 , C_2H_5Cl soln., with phenolphthalein, naphthol or thymolphthalein as indicator. Such pptn. of the fatty acids from a hot mixt. of MeOH and $CHCl_3$ gives a granular ppt. easily filtered and can be used as a purifying means to prep. pure acids. Since the Ba salt of the brominated oleic acid is readily sol. in ether, $CHCl_3$ contg. a little H_2O or alc. and also in boiling dry EtOAc, while the Ba soaps of the satd. acids are nearly insol., a sepn. method might be developed on that basis, except for α -tetrabromolinolic acid which resembles the satd. acids in soly. P. ESCHER.

Identification of extracted oils. C. B. CAROCCI. *Ind. olii grassi* 1927, VII, Squibb Abstract Bull. 2, A-112(1929). C has found that in hundreds of samples of olive oils tested in one of the Italian expt. stations, the method recommended by Fachini and Dorta, for the identification of extd. oil according to Morawski's reaction has given exact and sharp reactions, even in samples contg. very small fractions of extd. oil. C further recommends Bellier's reaction generally characteristic for the presence of peanut oil, which method is a valuable aid in the identification of inferior grades of olive oil. Where as peanut oil in alc. soln. forms a flocculent ppt. with KOH, which ppt. dissolves in the alc. at temps. above 40° , the olive oils of inferior quality show turbidity or at most a gelatinous pptn. with the same reaction, which does not disappear even upon heating the alc. soln. to 70° . This reaction has not failed in any case and becomes uncertain only in the presence of larger amts. of peanut oil. No further information regarding these reactions is given. H. G.

Determination of the adsorption power in the discoloration of oils with bleaching earths. ANDERS WIBERG. *Z. anorg. Chem.* 41, 1338-42(1928). Data from the literature cannot be compared, because they were taken without making sure that the equil. point was reached. A method and app. are described by which the equil. point is rapidly reached. The temp. is 98° and a stirrer is used, revolving at 200 r. p. m. A higher temp. is not advisable because the oils would be acted upon by air, and because at 98° it takes only 15 mins. to reach the equil. point. The method was tested with cacao butter and soy oil. ALBERT L. HENSLER.

Determination of water and oil in soy beans. L. BURSCH. Hamburg. *Maschinen-Zhironoe Delo (Oil & Fat Ind. (Russia))* 1928, No. 2, 13-5. The use of Marcussen's H_2O detn. app. is recommended. Xylene is used as H_2O carrier. The results obtained by this method for whole beans are considered to be more accurate than by the old method of drying the beans at steam temp., as no losses are incurred through evaporation of volatile compds. present in the oil. Oil content of the whole bean is calcd. from detns. of H_2O content of the whole bean and oil and H_2O contents of the bean meal. A. A. BOEHLING.

Detection of coconut and palm-kernel oils by the lauric acid test. J. GROSSERUD AND A. MIERMEISTER. Staatlichen Nahr.-Untersuchungsanstalt, Berlin. *Z. Untersuch. Lebensmittel.* 56, 423-37(1928); cf. C. A. 23, 914. From 1 to 100 mg. of the fat is saponified in a test tube with 2.5 cc. of alc. 0.5 N KOH and evapd. The residue, dissolved in 2 cc. of H_2O , is mixed with 2 cc. of glycerol (300 g. per l.), placed for 5 mins. in a boiling water bath and pptd. with 2 cc. of $MgSO_4$ (150 g. per l.). After filtering while hot through a thick filter, and refiltering the first portion of the filtrate, a clear filtrate indicates no lauric acid is present; a turbidity indicates 10% or more of lauric acid (20% coconut oil) while a heavy white ppt. is proof of the presence of a large quantity of coconut or palm-kernel oil. By increasing the quantity of the sample, and using certain refinements, as little as 0.5% of lauric acid (1% coconut oil) may be detected. Lauric acid in small quantities was found in butter, hardened peanut and cottonseed oils. Cacao, soy bean and blubber oils gave neg. tests for lauric acid. C. R. F.

The future of the manufacture of oils from the skins of pressed grapes. JULIAN GIL MORRIS. *Quim. ind.* 6, 31-2(1929).—The solvent recovery problem has been solved. More powerful hydraulic presses are required. Continuous operation is required to avoid rancidity and driers were installed for the same reason and also to facilitate extn. and solvent recovery. Fuel consumption was taken in hand. The ash

of the skins, being rich in phosphates, makes a good fertilizer. Recently, dry destructive distn. was adopted in Italy and Spain to obtain products similar to those from wood distn. Hydrogenation of the oils produced from the skins gives a product contg. up to 60% of satd. hydrocarbons. These methods have been adopted to defend the industry from extinction.

Oil from *Luffa acutangula* and *cylindrica*, *Sisymbrium loeselli* L. and *Thlaspi arvense*. S. IVANOV AND N. TROITZKII. *Masloboino Zhirovoe Delo*. (Oil & Fat Ind. (Russia)) 1928, No. 1, 30-1.—The seeds of *Luffa acutangula* (1), *L. cylindrica* (2), both grown in south Russia, *Sisymbrium loeselli* L. (3), and *S. sophia* (4), both grown in middle Russia, and *Thlaspi arvense* L. (5), grown in middle-east Russia have, the following characteristics:

Nö.	% oil	Shell	Kernel	Oil in kernel	Acid no	I no	Sapon. no.
1	..	53.4%	46.6%	40.30%	7.92	114.8	..

A. A. BOEHTLINGK

Rhodan value of fish oils. H. P. KAUFMANN AND A. PROCKE. Univ. Jena. *Arch. Pharm.* 267, 229-32 (1929). An exptl. study of the rhodan as compared with the I value of certain fish and liver oils. A 24-hr. treatment is necessary to obtain a max. rhodan value. *Oleum jecoris aselli*, album showed a value of 107 (I value 168). A dozen different brands of cod-liver oil showed a variation in the rhodan value of 96.5 to 104 (I value 149 to 167), while various fish oils varied from 74.5 to 112 (I value 75 to 178).

W. O. E.

Modern direction of soap manufacture. KARL BRAIN. *Chem. Tech. Rundschau* 44, 280 (1929). A discussion of chem. and phys. factors which must be controlled in the manuf. of grain soaps.

E. PICKERING

Inhibition of the corrosion of aluminum by soaps. H. V. CHURCHILL. Am. Inst. Mining, Met. Eng. *Tech. Publication* No. 176, 3-6. Effective inhibition to corrosion of Al tubes by shaving creams is obtained by adding 0.20% Na_2SiO_3 to the soap.

B. E. ROETHLI

Solvents and dispersing agents (for oils, etc.). Fr. pat. 646,816 13. Heaters for oil refining (Fr. 646,642 and 646,643). 1. Apparatus for effecting separation of oil, gas and water by gravity and centrifugal action. U. S. pat. 1,705,669 1. Apparatus for separating oil and water by gravity. U. S. pat. 1,705,077. 1.

Fatty acids. OEL- UND FETT-CHEMIE GES. Brit. 286,079, Aug. 26, 1927. High-grade fatty acids are obtained from waste or low-grade material by distn. in a high vacuum, e. g., split fatty acids from bones or from cotton oil soap stock are distd. at a pressure of 4 mm. or less in a fractionating column app. until the residue amounts to 20%. Cf. C. A. 22, 2076.

Refining fatty oils. HENRY ODGEN. U. S. 1,705,824, March 19. Fatty oils such as cottonseed oil contg. free fatty acids and a small quantity of water are mixed with a finely divided solid adsorbent carrier material such as fuller's earth intimately assocd. with NaOH or other dry alkali in sufficient quantity to remove the impurities and water from the oil. U. S. 1,705,825 specifies a similar process with addn. of just sufficient water to promote rapid neutralization and agglomeration of the resultant soap stock.

Purifying oils. I. G. FARBENIND. A. G. (Martin Luther and Kurt Pieroh, inventors). Ger. 471,076, July 6, 1926. The lower alkyl formates or mixts. thereof are used as extg. agents in the purification or sepn. of oils. Examples are given describing the deacidification of sesame oil, the refining of a Mexican crude oil distillate and the extn. of a resin from the residues left after distg. the destructive hydrogenation products from a crude mineral oil, HCOOMe being the reagent in each case.

Apparatus for extracting oil from fruit and oleaginous grain. ANDRÉA ACQUARONE. Fr. 646,249, May 12, 1927.

Treating blubber. KURT BUCHHOLZ. Ger. 471,096, May 8, 1925. In extg. train oil, etc., from blubber, the sliced blubber is simultaneously pressed and triturated so that the cells are disintegrated and their contents set free. Suitable app. is described.

Soap. H. WATZMANE SÖMME. Ger. 471,140, Sept. 1, 1926. A neutral superfatted soap is prepd. by using an ordinary superfatting compn. mixed with NaHCO_3 .

It is stated that the reaction of the NaHCO_3 with the excess of alkali in the soap base is not completed until the soap is in use, and that the soap is accordingly better preserved.

Soft soap. OSCAR H. CARLSON. U. S. 1,705,852, March 19. A mixt. is formed of castile soap 3 lbs., NaHCO_3 4 oz., borax 4 oz., glycerol 4 oz., coconut oil 2 oz. and soft water 10 qts. This mixt. is boiled and there is added to it a mixt. formed by boiling together stearic acid 1 lb., sal soda 8 oz. and water 6 qts., the combined mixt. is boiled and "sulfuric ether" 2 oz. is added, to form a product which may be used for removing grease, tar, etc., from the hands or fabrics.

Washing powder. MAHLON J. RENTSCHLER (one-half to William R. Jeavons). U. S. 1,707,024, March 26. A mixt. suitable for use in washing dishes, clothes, etc. is formed of equal quantities by wt., of neutral tallow soap, Na_3PO_4 , sal soda, NaHCO_3 , and Glauber's salt.

28—SUGAR, STARCH AND GUMS

F. W. ZERBAN

Problems of the sugar industry. M. JEDLINSKY. *Lišty Cukrovar.* 47, 248-50 (1929).—A discussion. FRANK MARESH

Recent important changes in the sugar industry. K. RETTER. *Magy. Mérn. Ép. Közl., Supplement, Techn. és Körgazd.* 6, 73-4 (1928).—A brief summary is given of recent developments in raw-sugar production and refining, and in modern regeneration of bone black and of vegetable carbons. The position of the sugar-refining industry depends chiefly on the economic situation, price and production, and further on the duties on raw sugar. Modern sugar factories should produce and use steam very economically. Several factories have electrified their plants, leaving the remaining old steam engines as a reserve for an emergency. S. S. DE FINÁLY

The Argentine sugar crop of 1926. WM. E. CROSS. *Rev. ind. agr. Tucumán* Nos. 3-4, 67-94 (1928).—Data relating to sugar production in Australia, Argentine, Hawaii, Porto Rico, Java, Natal, Cuba and other countries are given. An analysis of mill performance, yield and loss is included for installations in Hawaii, Java, Natal, etc. Twenty-eight tables show the collated data. S. L. B. ETHERTON

Sugar-cane experiments at Allai. F. A. STOCKDALE. Ceylon Dept. Agr. *Tropical Agr. (Ceylon)* 71, 343-7 (1928).—Analyses are given of a no. of varieties of cane raised at Allai. A. L. MEHRING

Sugar-cane experiments. R. C. WOOD. Imperial Coll. Trop. Agr. St. Augustine *Trop. Agr. (Trinidad)* 5, 106-7 (1928).—Analyses of the juices produced from several varieties of canes are compared. All varieties gave relatively low sucrose contents because of the high relative humidity during the growing season. Badilla gave the highest percentage of sucrose, 15.37%. A. L. MEHRING

Experimental sugar factory. W. SCOTT. Imperial Coll. Trop. Agr. St. Augustine *Trop. Agr. (Trinidad)* 5, 202-3 (1928); cf. C. A. 22, 2480.—Reports for the years 1927 and 1928 are given. The following statistics cover the year 1928: av. analysis of cane, sucrose 13.09, fiber 12.80%; av. analysis of megass, sucrose 4.31, fiber 47.33 and moisture 47.29%; av. analysis of juice, sucrose 15.62% and glucose ratio 10.04; molasses, av. apparent purity 42.38; cane ground, 1272.65 tons; sugar made, 127.88 tons; cane syrup made, 800 gals., and fuel oil consumed 92.80 tons. Of the sucrose in the cane 91% was recovered in the juice and 75% in the final sugars. A. L. MEHRING

Phosphates in cane juice. H. B. SPRINGER AND J. G. DAVIES. Unpublished thesis in the library of the Imperial College of Trop. Agr. St. Augustine, Trinidad. A. L. MEHRING

The crystallization process in cane-sugar mills. K. W. GRANTZDÖRFFER. *Arch. Suikerrind.* 36, II, 1172-5 (1928).—The conditions necessary to obtain a grain of uniform size are discussed. Attention is called to the necessity of perfect circulation in the vacuum pan, obtained by better construction of the coils and even distribution of the feeding. Graining by introducing dust grain is to be preferred to the usual way of graining. P. R. P.

A modification of the sulfitation process. H. H. E. SUEBACH. *Arch. Suikerrind.* 36, II, 1187-9 (1928).—To obtain more complete pptn. of the colloids it is recommended to lime the raw juice to 250 mg. CaO per l., to heat to 55° , to hold the juice for about 5 min. at this reaction and temp., and then to add the balance of the lime and the SO_2 simultaneously to 7.4-7.8 p.p.m. as is done in de Haan's carbonatation process. Expts. showed that a clearer and lighter colored juice resulted; the color of the massécuites was also better. P. R. P.

Pan boiling. Its scientific control and the Zeiss industrial refractometer. S. J. SAINT. Dept. of Sci. Barbados. *Trop. Agr.* (Trinidad) 5, 279-83(1928).—The phys. chemistry of sugar crystn. from aq. solns. is discussed. Observations made at the Sandy Lane Factory in Barbados, using the 3-strike system indicate the opt. coeff. of supersatn. for sirup strikes to be 1.15, for strikes of mixts. of sirup and molasses during the drawing-in period 1.2, and for the boiling-off process 1.35 to 1.4. A table is given by which the correct concn. for the mother liquor in the pan can be detd. when the refractometer reading, the vacuum and the level of massecuite are known. Data are tabulated indicating that brasmoscope control is more difficult and less reliable than refractometer control.

A. L. MEHRING

• **Leaf reddening in some varieties of sugar cane.** G. L. FAWCETT. *Rev. ind. agr. Tucumán.* Nos. 3-4, 104-5(1928).—Microscopic examns. of the cells of the epidermis showed a colored liquid. Parasitic cryptograms are excluded as the cause, and it is considered to be due to the low temp. of 10° that was known to have prevailed at some time during the growth.

S. L. B. ETHERTON

The desirability of raising sugar beets for yield. OTTOKAR FALLADA. *Listy Cukrovar.* 47, 242(1929).—A discussion.

FRANK MARESH

The relation between the sugar content of beets and the yield. E. JELINEK. *Listy Cukrovar.* 47, 274(1929).—If d = sugar content of beets, z = total losses, m = sugar in the molasses per 100 beets, v = yield computed for 88%, p = polarization for the above yield, then $v = \frac{[(d - z - m) \times 100]}{p}$; but if $v = d$, then $\frac{100(d - z - m)}{p} =$

d also. If the polarization of a sugar based on an 88% yield is around 93%, $(93 + x)$ may be written for p , where x may have a neg. value; then $\frac{100(d - z - m)}{93 + x} = d$, and $z + m = 0.07d - \frac{d \times x}{100}$. Since x is not greater than 0.5, the $\frac{d + x}{100}$ will be about 0.1

and may be neg. when x is neg. Then $z + m = 0.07d \pm 0.1$. With a yield of 0.88, the total losses of sugar and the sugar in molasses will be: for a 17% digestion, $z + m = 1.10 \pm 0.1$, for an 18% digestion, $z + m = 1.26 \pm 0.1$, for a 19% digestion, $z + m = 1.33 \pm 0.1$. This shows that the yield can approach the sugar content of beets when the total losses and the sugar in molasses are minimal at the same time. This rarely occurs.

FRANK MARESH

The use of the De Vecchis method of working beets. JANKO PROCHÁZKA. *Listy Cukrovar.* 47, 260-3(1929).—For the Slovakian mill, P. finds the method limited economically by the large consumption of coal.

FRANK MARESH

Extraction of sugar from grape-vine prunings. CARRIÈRE. Faculté des Sciences de Montpellier. *Rev. vit.* 70, 37-47(1929).—With 20 g. vines and 200 g. acid soln. the following results were obtained: with 7.3% HCl, max. sugar 32%, time 2 hrs.; with 3.65% HCl, max. sugar 35%, time 4 hrs.; with 1% HCl, max. sugar 35.4%, time 7 hrs.; with 1% H₂SO₄, max. sugar 32%, time 13 hrs. No difference was found between 1 to 7 and 1 to 10 ratios of solid to soln. Different varieties of vines gave the same results, and up to 3 months elapsed time between gathering and hydrolyzing no difference in amt. of extractable sugar was observed. For larger-scale operations 20 l. Pyrex flasks were used and several battery processes of hydrolyzing and washing were studied. The most successful of these permitted the extn. of 31.5% sugar from the vines and resulted in a sugar concn. of 8% in the hydrolyzate. The actual decrease in the wt. of the vines amounted to 41.4%, the difference in percentages being accounted for by extd. salts and acids. Max. yields of alc., amounting to 48.6% of the sugar present in the hydrolyzate, were obtained by neutralizing 85% of the acidity with CaO, 5% with NH₃, and 5% with K₂CO₃, followed by the addn. of 3 g. Na₃PO₄ per l. of soln. and NaOAc equiv. to 5% of the acidity, inoculating the slightly acid soln. with pure culture yeast and fermenting for 3 days. Nutrition studies of feed prepd. both with the original sugar soln. and with the residues after fermentation are reported.

K. S. MARKLEY

The constitution and physical properties of molasses. K. ŠANDERA. *Exp. Inst. Cz. Sugar Ind., Prague. Listy Cukrovar.* 47, 251-9(1929); cf. C. A. 23, 2062. Metallic containers with close fitting stoppers were filled with molasses, an excess of sugar crystals, and a 200 gm. wt. for mixing. Various brands of com. molasses were used, and the sugar was of the brand "Export Crystal extra fine" measuring 0.06 mm.³. The vessels were immersed in thermostats and removed periodically to det. the refractive index of the soln. Four hrs. at 60° dissolved a large amt. of sugar, but complete equilibrium was not attained. About 48 hrs. are necessary for complete crystn. of the dissolved sugar. Several molasses having the same chem. consta., as n , ash, etc., showed wide ranges of

yield in crystals. This is due to variations in prepg. the molasses, as stirring, mixing, etc. A soln. of molasses and sugar satd. at 60° and crystd. at 20° for 48 hrs. will attain an equil. between crystals and soln.; upon cooling the soln. to 20° and continuing the crystn. at 20°, less sugar crystallizes than was dissolved. Ash content, total solids, or K:Na ratio show no indication as to when the sugar has been completely removed from soln.

FRANK MARESH

The limit of sugar extraction from cosettes in the diffusion process. S. S. KUTZEV. *Bull. Sakharotrestia (Bull. of the Sugar Trust)* 1928, No. 9, 65-8.—Several expts. were performed on extg. juice from beets. The juice drawn off from the diffusion battery was 120-160% of the wt. of beets. The time of diffusion was 120-200 mins. The sugar content of the pulp decreased from 0.52 to 0.17%, and that of the press water from 0.26 to 0.045%, corresponding to an increase of juice withdrawal from 120 to 160%. The purity of the juice from the last cell was resp., 45.6 and 36.9. In the first case 119 parts and in the second, 188 parts of non-sugar are dissolved per 100 parts of sugar. By defecation and carbonation a large part of the non sugars is pptd.; when drawing 110, 120 and 160% of juice, 33, 66 and 75% (on sugar) of the non sugars is eliminated. If 160% of juice is drawn (on wt. of beets), more org. non sugar is dissolved, which passes with the juice through the defecation and carbonation and adds to the color of the product. Better results could probably be obtained by reducing the time of diffusion, the com. optimum is unknown. A process of boiling massecuite with introduction of seed into the vacuum pan to start crystn. is also described; it is advisable to use it when spontaneous crystn. is difficult.

V. E. BAIKOV

Experiments on clarifying diffusion juice with magnesium sulfate instead of carbon dioxide (process of V. V. Shkatelov). V. I. KUZNETSOV. *Nachukn. Z. prikl.* 7, 158-63 (1928).—MgSO₄ may be used for clarification of diffusion juice instead of CO₂. In this reaction sucrose is liberated while Mg(OH)₂ and CaSO₄ are pptd. Mg(OH)₂ like Al(OH)₃, forms compds. with org. coloring matters. The solv. of Mg(OH)₂ in H₂O is only 0.0018 % by wt. To eliminate CaSO₄ from the juice it is necessary to heat it almost to the b. p. During evapn. the juice becomes cloudy because of pptn. of CaSO₄. To the diffusion juice, heated to 90°, 0.6% CaO and 1.5% CaCO₃ on the wt. of beet was added. After 20-25 mins. the juice was filtered and pumped to the satn. tank, maintained at the same temp. MgSO₄ soln. was added and the juice filtered through filter presses. The alk. of the filtered juice was 0.02%, and of the thick juice after evapn. 0.05. After sulfitation the thick juice was filtered through mech. filters, and a perfectly clear juice was obtained. 55.2% of white sugar of good quality was extd. on the wt. of massecuite. Low products served for massecuite of the second crystn. The expts. gave very satisfactory results. Conclusion from expts. Use of MgSO₄ instead of CO₂ with 0.75-0.5% of CaO and 1.75-1.60% of CaCO₃ on the wt. of beets and sulfitation of the thick juice gives as good results as using 2% CaO with double carbonation and sulfitation of thick juice. Mg(OH)₂ is a powerful adsorbent of coloring matter of juice. The small amt. of CaO required for the process permits buying of the lime instead of manufg. it in the factory. A defect of this process is the large quantity of CaSO₄ in the juice to be evapd.

V. E. BAIKOV

The determination and character of the alkalinity of raw sugars. VL. PREININGER. *Exp. Inst. Cz. Sugar Ind., Prague. Listy Cukrovar.* 47, 263-73 (1929).—P. measured the alk. of a large no. of raw sugars and recommends the following 2 methods for industrial work. I. For control work, 8 g. of sugar is weighed into 3 test tubes and dissolved in 20 cc. neutral distd. H₂O. To one test tube is added 10 drops of an indicator (0.2 cc.), the 3 are stoppered, mixed and compared in a Walpole comparator with a standard borax soln. made by dissolving Na₂B₄O₇·10H₂O 19.108 g., H₂BO₃ 12.404 g. and NaCl 2.925 gm. in 1 l. neutral distd. H₂O. II. The next detn. is made during an analysis from one weighing. A double normal wt. of raw sugar is dissolved to a vol. of 200 cc. in neutral distd. H₂O, and the H₂O detd. by a Pulfrich immersion refractometer. During the detn. of ash by the cond. methods, a conductometric titration is made on a 25-cc. sample. For a color detn., 2 25-cc. samples are placed in the cups of an objective photometer; to one soln. is added 10 drops of an indicator, and the increase in coloration is noted in % absorption. From curves the pH of the soln. is detd. The Walpole comparator may be used instead of the objective photometer, following method I. The remainder of the soln. is clarified with (CH₃COO)₂Pb and used for detg. polarization. From this simple pH detn. the state of alk. is inferred. The alk. of raw sugars is caused by basic substances among which the carbonates range from 33-50%. This information is gained by detg. the CO₂ and N₂ directly in raw sugars and from conductometric titration curves. The quantity and character of the non-sugars have been inferred from the same curves. Bromothymol blue and phenolphthalein

were used, for they are not affected by the reacting salts. A sugar of p_H 8.0–8.6 is medium in alk.; one of p_H 7.0–8.0 is mildly alk. and cannot be stored long, though inversion may not occur; at a p_H below 7.0 the sugar is acid and is in danger of becoming inverted.

The p_H values of sugar media and the possibility of their inversion. H. COLIN AND A. CHAUDUN. *Bull. assoc. chim. suc. dist.* 45, 626–42(1928).—A review.

Standardization of the boiling of fillmass in the refinery. M. YA. DEGTYAR. *Nauchnue Zapiski* 7, 26–33(1928). The injection of refined sugar powder at the moment of satn., with continuous flow of liquor to the vacuum pan is the best of 3 different processes of boiling refinery fillmass. This process does not require a very experienced boiler and produces regular crystals without false grain. 8.1% of the time of boiling and 15.2% of the time of further crystn. is saved. Regular crystals of slightly better quality and color are obtained.

Economical steam pressures in sugar mills. O. T. KORITNIG. *Listy Cukrovar.* 47, 216–8(1928).—A discussion.

The influence of carbon monoxide and other components of a saturating gas upon the rate of saturation. R. SIGMUND. Exp. Inst. for Cz. Sugar Ind. Prague. *Listy Cukrovar.* 47, 243–8(1929). A 15% soln. of clear refined sugar soln. was satd. with CO_2 prepd. by igniting $CaCO_3$. The $CaCO_3$ was pptd. by mixing $CaCl_2$ and $(NH_4)_2CO_3$. The CO was prepd. from formic acid. The rate of satn. of the refined sugar soln. with CO was reduced by a small (0.5%) quantity of CO_2 , the time to reach equil. varied from 270 to 350 mins. With 10% CO , the rate of satn. is reduced 50%. Other constituents of com. CO_2 , as H_2S and tar vapors, have an insignificant effect. Hydropectin and aspartic acid decrease the rate of satn. about 15%.

Permutite in the purification of sugar juices. I. MUTTI AND C. REGINELLI. *Zymol. chim. col. Zuccheri* 3, No. 3, 91–5(1928). The elimination of Na and K salts from sugar juices by means of Ca permutite was studied. Ca permutite was prepd. by treating Na permutite with a Ca salt soln. for some hrs. and washing. Sugar-beet paste was mixed with H_2O at 40° for 2 mins., the ext. sepd. and the process repeated with always warmer H_2O . The dil. ext. was concd. to the strength of ordinary ext. having a purity of 77.3 and polarization of 6.8. Ten g. Ca permutite was added to 200 cc. ext., the mixt. agitated 6 hrs., allowed to settle and filtered. One hundred g. of untreated ext. had 0.8586–0.8752 g. ash, and 100 g. of treated ext. 1.1512–1.1620 g.; the purity reached 78.26 and the polarization 7.2. Two hundred cc. of sugar juice was decolorized with 10 g. more Ca permutite in the warm, to a light yellow, like C-filtered juice. Five samples gave an av. purity of 79.50, the ash contained 97.90% less Na_2CO_3 and K_2CO_3 than that of the untreated juice.

Quality and quantity of wash water from bone-black filters. M. I. NAKHMANOVICH AND J. F. ZELIKMAN. *Nauchnue Zapiski* 7, 201–22(1928). It is better to send wash water from 5° to 0° Bè. and from 0° to last washing into evapn. with low products, than into the melt. Non-sugars carried by the wash water are poorly adsorbed by chars and, therefore, easily washed out. These non-sugars remain not only in unfiltered juice but also in filtered. With the same speed of washing the filters, the amt. of wash water returned to refining is in different refineries from 8 to 18% of the wt. of melted sugar and 90–100% of the wt. of bone black. Wash H_2O from 5° Bè. to last washing, returned to refining, represents 85% of all wash H_2O . With decreasing d. of the wash water, from 5° to 0° Bè., the purity drops from 92.9 to 77.7, and the acidity of the wash water increases. Reducing the speed of washing the filters gives wash H_2O of low purity and high acidity. With wash H_2O from 5° Bè. to last washing, returned to melt, 0.04% of non-sugars on the wt. of all raw sugar melted is returned, which represents 13% of all non-sugar entering fabrication with the raw sugar.

Studies on filter cloths. K. ŠANDERA. Expt. Inst. Cz. Sugar Ind., Prague. *Listy Cukrovar.* 47, 275–80(1929).—The strength of cloth as detd. by the self-elongation is not a governing factor, for only about 30% (on an av.) of the strength is consumed when the cloths are removed. Cotton is used until 63% of the original strength is lost, jute until 46% and only exceptionally until 58%, and linen until 63%. The percent elongation before tearing is variable and decreases with usage from 3–5%. For cotton it is 20–30%, for jute 10–15%. For linen the % elongation varies as much as 50% in the two directions of weave. The elongation of cotton cloths after soaking in water shows an increase of 4%. For cloths which have been used in practice, this test shows a decrease of 1%; jute, linen and most linen-cotton cloths shows an increase of 1%. The change of the rate of flow through the cloth during use shows an increase of 30% after 30 mins. of boiling. Ordinary use increases the time of flow for molasses 15–26% until

completely clogged, but decreases it for distd. H_2O , which has been made slightly acid, for the same cloth. This is not dependent upon viscosity, for in some cases it requires more time to pass neutral distd. H_2O than molasses. The absorption of light is increased with a denser weave and with incrustations. New cloths show a relative absorption of 70-80% for cotton, and the denser woven ones are above 80%. Usage shows a wide variation in the change of absorption; the decrease in relative absorption varies from 15-80% for cotton. Jute shows the greatest amt. of incrustation. Linen cloths become more transparent, for the fibers become thinner with use. With an acid treatment, the relative transparency of cotton is increased regularly 10-20%; no such regularity is found for jute or for a linen-cotton mixt. The quantity of incrustation is measured by weighing the ash. Used cotton filters show 8-18% ash; linen and linen-cotton combinations show greater variations. Treatment with HCl reduces this ash content 10-30%, in exceptional cases 50-80%.

Pressure evaporation. KAREL VESELY. *Listy Cukrovár.* 47, 214 6(1928).—Polémique, with operating data from the sugar mill Wisington.

FRANK MARESH

Choice of the temperature gradation in multi-stage evaporators in the sugar industry. PAUL KOHN. *Chem. App.* 16, 13-4, 37-8(1929).—Means of selecting the most favorable temp. gradation, and methods of calcg. the heating surfaces and heat transmission for double and triple effects are given.

J. H. MOORE

Automatic apparatus for adding milk of lime at the second carbonation. A. SAMUS. *Nauchnie Zapiski* 5, 396-7(1928).—The automatic mixer described can be regulated so that a certain amt. of milk of lime enters into the carbonation tank at each revolution of the stirrer.

V. E. BAIKOW

Continuous automatic counter-current extractor for starchy and saccharine substances with press elevator. G. MEZZADROLI AND G. MAZZINI. *Zymologica* 3, 109-12(1928).—Four or 6 superposed, steam-jacketed, horizontal cylinders are provided with screws, which are driven from the outside and which have tubular axes for steam heating. The material, such as beet slices, is fed into the uppermost cylinder through a charger with hermetic seal and passes from end to end of each cylinder in turn. Water, previously pumped through a heater, traverses the cylinders in the opposite direction, to be discharged through a grid which is kept clear by the screw moving against it. The exhausted material is carried by a screw elevator against a pressure cone and so freed from most of the absorbed liquid. The app. is simpler than the diffusion battery, and requires less space and less labor, while the heat is more efficiently utilized and initial and maintenance costs are diminished.

B. C. A.

Determination of starch with the help of the interferometer, according to O. Wolff. B. ELEMA. *Z. angew. Chem.* 42, 199-201(1929).—The Wolff method (cf. C. A. 18, 2821, 3123) gives a starch content which is always deficient, because during trituration of the vegetal material with sand and water, a portion of the starch is dissolved. It is advisable to triturate the blank with sand also, to make the conditions as similar as possible, but this does not account completely for the deficiency. Starch grains triturated with sand for 10 mins. are easily acted upon by diastase. ALBERT L. HENNE.

Determination of starch in potato pulp. C. VON SCHERLE AND G. SVETKEY. *Z. Spiritusind.* 51, 290-1(1928).—Because of the presence of pectinous material the method of detg. starch in cereals gives too high results. Better results are obtained by quickly bringing the starch to a sol. form, pptg. the pectins with lead acetate, removing the excess of acetate with Na phosphate and detg. the starch in the filtrate by the polarimeter or refractometer.

A. SCHLEIZ

St. Vincent arrowroot. G. WRIGHT. *Trop. Agr. (Trinidad)* 5, 162 6(1928). The local process of mfg. starch from arrowroot is described.

A. I. MEHRING

The composition and nutritive value of sugar-beet pulp (WOODMAN, CALTON 12. Inexpensive filter for milk of lime (BURCHKOVSKI) 1. Certain soil properties in relation to sugar-beet growing (NEWLANDS) 15. Recent literature on activated carbons (KAGANOV) 18. The condition of the micelles in starch (SAMBC) 2. The microscopic examination of starches (GARNER) 12. Titration curves of some liquids titrated with phenolphthalein (alkaline sugar solutions) (MAJER) 7. Preparation of negatively charged sols by means of tartaric acid. II. The colloidal nature of Fehling solution (DEMANSEN, CHALISEV) 2. The fermentation method of preparing glycerol (PRNKOVSKI) 16. Drying beets by coiled heating pipes within a stack of the material (Brit. pat. 295,482) 12. Drying beets (Brit. 295,801) 12. Cooling steam (in sugar manufacture) (Ger. pat. 471,225) 13.

Treating sugar beets. B. J. OWEN and C. STRAD. *Brit.* 295,619, April 13, 1927.

Fresh whole sugar beets in mass or in piled layers are slowly dried in a continuous current of air at a temp. of about 27–32° with which CO₂ or SO₂ may be mixed. An app. and various details and modifications are described.

Apparatus for continuous saturation of sugar-beet juice. M. P. NOGACHEVSKII. Russ. 5310, May 31, 1928. Mechanical features.

Purifying sugar juices. G. E. VAN NES. Brit. 295,831, Aug. 18, 1927. After adding a base such as lime and "over-satg." with CO₂, the soln. is heated to not over 60°; more lime is added until an alky. of over 0.3 g. of lime per l. is obtained and the clear juice is sepd. by decantation. The turbid juice is further carbonated and heated to 80°, filtered, and together with final clear juice, may be added to a new batch of raw juice.

Material for decolorizing sugar. BÜTTNER-WERKE A.-G. and F. KLEINMANN. Brit. 295,623, May 14, 1927. See Fr. 635,916 (C. A. 22, 4741).

Crystallization apparatus for sugar solutions, etc. FERNAND LAFEUILLE. Ger. 471,075, June 30, 1925. Rotary horizontal crystn. chambers fitted with longitudinal tubes for the circulation of cooling water are provided with means for arranging the circulation so as to obtain uniform cooling.

Glucose from starch. CORN PRODUCTS REFINING CO. Brit. 295,830, Aug. 15, 1927. See Fr. 638,956–7 (C. A. 23, 541). The acid hydrolysis of starch to dextrose is effected in the absence of catalysts tending to polymerize the dextrose. Carbons which do not contain catalytic ingredients and which are capable of absorbing these are used; fuller's earth or silica gel also may be employed. The vessel used has a non-catalytic inner surface such as a glass enamel.

Determination of starch in potatoes by specific gravity. A. G. LOGINOV. Russ. 5260, Apr. 30, 1928. The sp. gr. is detd. by slicing potatoes, stamping out cylinders from the slices with a thin-walled tube of a known vol., and weighing. The amount of starch is then calcd. from the sp. wt.

29—LEATHER AND GLUE

ALLEN ROGERS

The hydration of animal skin by the volume-change method. EDWIN R. THEIS AND HARVEY A. NEVILLE. Lehigh Univ. *Ind. Eng. Chem.* 21, 377–9 (1929).—When gelatin jelly or animal skin swells in contact with aq. solns., there is a decrease in total vol. of the system protein plus soln. which can be measured by means of a simple dilatometer. When fresh-steer corium was soaked in water or dil. HCl, the vol. of the system decreased with time to limiting values corresponding to the swelling of the protein matter. But with cured hide in water or in solns. of HCl more dil. than 0.01 N, the vol. of the system decreased to a minimum in 3–6 hrs., then increased to a max. in 36–48 hrs., and then decreased again. With 0.1 N HCl, the increase did not occur. The decreases are attributed to the swelling of the protein and the increases to bacterial activity, resulting in degeneration of the protein. In contact with limewater or acid soln. of such concn. as to prevent bacterial action, only a contraction of the systems was observed.

J. A. WILSON

A new depilatory for the tanning industry. V. MASSERA. *Laboratorio Conceria Carini, Sondrio, Conceria* 36, No. 1103, Tech. Pt. 46 (1928).—A NaHS soln. of 25° B ϵ used as a depilatory has many advantages over Na₂S, especially because it is more economical and because in conjunction with lime it has a quicker depilating action than Na₂S.

G. SCHWOCH

Leather scrap and its chemical utilization. MARTIN MEIER. *Chem.-Tech. Rundschau* 44, 376 (1929).—By destructive distn. of leather scrap, there is obtained an inflammable gas, a liquid and a residue of animal charcoal contg. green dye known as *chrome oxide green*. The liquid consists of an aq. and an oily phase; the first contains NH₃, *pyrocatechol* and *pyrogallol*; the second is *pyrrole*. From the latter may be synthesized iodole and perfumes, especially *jasmine*. Pyrrole may be detected by the red coloration it imparts to cellulose paper, which has been soaked in concd. HCl.

E. PICKERING

Montan wax (Brit. pat. 296,145) 21.

Tanning. I. G. FARBENIND. A.-G. (Hermann Schütte, inventor). Ger. 466,440, July 11, 1925. Tanning material is prepd. from cellulose sulfite lye by condensing

it in the presence of H_2SO_4 and in the absence of water, with aromatic hydrocarbons, carbazole, or their sulfo acids, under such conditions that no free hydrocarbon or sulfonic acid remains. Thus, finely powd. dehydrated cellulose sulfite lye is mixed with H_2SO_4 , and finely powd. naphthalene is allowed to react till no free naphthalene remains. Anthracene is also given as an example.

Tanning materials. EDUARD JENA. Ger. 468,266, July 26, 1922. Resin or wax is treated with a large excess of fuming H_2SO_4 to break it down to sulfonated oxidation products, which are sol. in water and suitable for tanning. Thus, 300-400 parts of fuming H_2SO_4 contg. 20% anhydride is cooled and added to 100 parts of colophony powder. The product contains no C particles and is sol. in water.

Synthetic tanning material. JOSEF SCHÄFER (to J. R. Geigy (Akt. Ges.)). U. S. 1,706,325, March 19. Salts of H_2SiF_6 , such as Na_2SiF_6 , are mixed with salts of synthetic tanning substances resulting from the condensation of phenolsulfonic acids and CH_2O (rendered sol. in water by the presence of sulfo groups) in order to develop tanning properties, which the salts alone do not possess. Cf. C. A. 23, 730.

A compound for the analysis of tanning materials. V. S. SADIKOV. Russ. 5117, Apr. 30, 1928. A material contg. collagen is treated with caustic, dehydrated with alc., acetone, etc., and dried. Pax wax may be used as the material contg. collagen.

Leather. I. G. FARBENIND. A.-G. (Adolf Benischek, inventor). Ger. 468,094, Oct. 22, 1925. Liquid triaryl phosphates are employed as adhesives and preservatives for leather.

Drying leather. V. G. WALSH. Brit. 295,804, July 7, 1927. Vegetable-tanned leather is treated with substances such as $\text{Al}(\text{OH})_3$ having a high adsorptive capacity for the tan so as to remove excess from the surface layer of the leather and avoid deleterious oxidation during drying. Various details and modifications are described. Cf. C. A. 22, 3315.

Greasing leather. I. G. FARBENIND. A.-G. Fr. 646,395, Dec. 27, 1927. Sulfonated fatty acids of suint are used for greasing leather before or after dyeing.

"Leather substitute." R. P. ROSE and A. F. OWEN (to Mechanical Rubber Co.). Brit. 295,387, Aug. 11, 1927. A product of the "sole leather type" is formed by treating fiber such as cotton with an aq. rubber dispersion, forming the material into a wet sheet, cold-pressing at 50-500 lbs. per sq. in. (or in 2 stages up to 1200 lbs.), drying, and hot-pressing (at about 107-155°) at 1200-2000 lbs. per sq. in. or higher pressure. The fiber is partly hydrolyzed by heating in water, and fillers, protective colloids such as glue, treated starches or casein, may be added. A coagulant is added preferably in 2 stages; various mech. details of forming sheets of the material are described.

C. C. DAVIS

Latex, its preservation and concentration. A survey of the patent literature of recent years. ALADIN. *Gummi-Ztg.* 43, 1047-9, 1105-6 (1929); cf. C. A. 22, 888. Eighty-five patents are included. C. C. DAVIS

The "freezing" of raw rubber. I. A. VAN ROSSEM and J. LOTICHIUS. Staatliel Kautschuk Forschungs-Institut and Tech. Hochschule, Delft. *Kautschuk* 5, 25 (1929).—The object of the investigation was to det. the nature of the changes which take place when rubber "freezes" and "thaws," *i. e.*, when it becomes hard and opaque at low temps. and subsequently becomes soft and elastic on warming. Measurements at increasing temps. of the d., hardness and light absorption of rubber which had been frozen for a long time showed a sharp decrease in all these values at 36-8°. There were no such breaks in the curves when rubber which had not been frozen was tested in the same way. These phenomena indicate that frozen rubber is partially crystd., and that the crystals fuse at 36-8°. This was further indicated by tests of the absorptive power of frozen and of unfrozen rubber for liquids, frozen rubber absorbing around 0.25 as much water as unfrozen rubber under similar conditions. Detns. of the heats of swelling of frozen and of unfrozen rubber in *PhMe* showed a difference which represented the heat of fusion of the rubber. The exptl. values of this heat of fusion varied but little with rubber from different sources and were 5.05 ± 0.28 cal. per g. of rubber. These values are not, however, the true value of the heat of fusion of cryst. rubber, for the proportion of cryst. rubber in frozen rubber was not known. This was in itself further evidence of partial crystn. Redetns. of the m. p. and of the change in d. on fusion of rubber kept frozen for 8 years showed an increase in the m. p.

from 31–3° to 35–7° and a change in the decrease of the *d.* on fusion from 0.029 to 0.031. These changes probably resulted from the growth of crystals during the 8 years. When frozen rubber was heated to 100° and was then frozen again and maintained at 4° and at –10°, resp., the *d.* and the hardness increased slowly over a period of some days, the rubber at 4° requiring longer than that at –10° to reach the max. *d.* and hardness which it showed originally. When these frozen rubbers were warmed, the decrease in *d.* and in hardness indicated a wide fusion range which was complete at 12–14°. The expts. indicate that crystn. depends upon 2 factors: (1) the no. of cryst. nuclei, and (2) the growth of the nuclei. The no. of nuclei increases with the degree of supercooling. At 4° and at –10° there is a great no. of crystals of much smaller size than those in rubber preserved for years. The different proportion and size of the crystals explain why the "m. p." after thawing and refreezing differed so much from that of rubber frozen a long time. In general the m. p. increased with the time during which the rubber was kept frozen. Furthermore the higher the temp. at which the rubber was kept frozen, the faster the growth of the crystals. Plasticizing rubber did not influence the subsequent crystn. phenomena on freezing. II. Röntgenspectrographic part. J. R. KATZ. Univ. of Amsterdam. *Ibid* 6–9.—Röntgenographic examn. of rubber frozen under the different conditions described (cf. above) confirmed the existence of crystals, and the fact that the "freezing" of rubber is its crystn. There was no conclusive evidence that any appreciable polymerization or depolymerization accompanies the crystn. process. The tendency of crystd. rubber to become amorphous when swollen in an org. solvent renders the isolation of crystals a difficult problem.

C. C. DAVIS

Diffusion of water through rubber. EARLE E. SCHUMACHER AND LAWRENCE FERGUSON. Bell Telephone Labs., New York City. *Ind. Eng. Chem.* 21, 158–62 (1929).—The rate of diffusion of water through rubber mixts. of various types was measured in 2 ways, in each case the rubber membrane being in contact with water on 1 side and a vacuum on the other; in 1 case the diffused water was measured by the vapor pressure of the water on the evacuated side, and in the 2nd case the diffused water was weighed after absorption by P_2O_5 . From calcns. based on the data obtained the following formula was derived: $\log_0[p_0/(p_0 - p)] = KA/(V)t$, where p_0 is the vapor pressure of the water on the reservoir side of the membrane, p the vapor pressure on the evacuated side, K a const., A the area of the membrane, V the vol. of the evacuated chamber which the water enters, and t is the time. K may be regarded as the *diffusion const.* and depends upon the thickness of the membrane, its degree of satn., the temp. and the age of the rubber. The results of the measurements show that (1) the rate of diffusion of water through a rubber membrane is inversely proportional to the square of the thickness; (2) the rate of diffusion diminishes greatly as the hardness increases; (3) the effect of satg. the rubber with water is to increase the rate of diffusion, probably because there is not only an increase in the vapor pressure of the water within the rubber but also a decrease in thickness of the membrane and (4) there is no close relationship between the rate of diffusion and minor variations in the compn. of the rubber. The rubber samples which were tested included pale crepe, smoked sheet and rewashed smoked sheet all cured with S, ZnO and an org. accelerator, rewashed smoked sheet cured with S, raw smoked sheet, pure rubber hydrocarbon, crepe low in protein cured with S and PbO, crepe treated with concd. H_2SO_4 , hard rubber, a rubber-"thermoprene" mixt. cured with S, ZnO and org. accelerator, rewashed smoked sheet cured with S and PbO and heavily loaded with silica, an inner tube mixt. (smoked sheet, S, ethylidene-aniline, "mineral rubber," ZnO and paraffin) and a white dental rubber.

C. C. DAVIS

A thermodynamic theory of rubber fillers. LOTHAR HOCK. Univ. Giessen. *Z. Elektrochemie* 34, 662–4(1928).—It is shown that simple cases of reënforcement of rubber mixts. by fillers can be treated on a strictly thermodynamic basis. In developing a theory of the reënforcing action of fillers, like C black and ZnO, the free surface energy between rubber and filler must be considered responsible for the increased work of breaking the loaded rubber. Attempts were therefore made to find a means of detg. this free energy. When a rubber-ZnO mixt. is swollen in benzine, the accompanying heat tone is not the sum of the heat of swelling of the same quantity of rubber and the heat of wetting of the ZnO when these are measured separately, the difference representing the *heat of adhesion of rubber and filler*. It also represents the *total surface energy* and is therefore not a measure of the free surface energy. Furthermore only part of the total surface of the filler comes into contact with the rubber because of incomplete wetting, and the greater the proportion of filler, the less nearly complete this contact. The *heat of wetting* is a function of the concn. of filler, and

reaches its max. value at infinite diln. of the filler. It can be detd. calorimetrically in an approx. way by extrapolation to 0 concn. of the diminishing heats of wetting. Calling U_0 the heat of wetting of 1 g. of filler when every particle is completely wetted, c the concn. of filler, and U , the actual heat of wetting, U/U_0 is the relative extent of actual surface contact. Thus with a rubber-C black (60-40) mixt., the heat of swelling is 0.1 cal. per g.; the heat of wetting of C black is 2.7 cal. per g. from which is calcd. a heat of swelling of the mixt. in benzine of 1.08 cal. per g. However, on account of the surface energy between rubber and C black, the observed heat of swelling was -0.15 cal., so that -1.23 cal. was the total surface energy. Therefore U_{10} was 3.08 cal. per g. of C black. The increase in the work of rupture due to the filler is the free surface energy A and may be detd. from the work expended in breaking the material. However, with increasing proportions of filler, a work of friction must become which is independent of free surface energy. Here too the limiting value A_0 can be detd. approx. by extrapolation to infinite diln. Expts. showed that the order of magnitude of A_0/U_0 is 0.5, i. e., about 0.5 of the calorimetrically detd. total surface energy takes part in the reinforcement, though the ratio varies with different fillers. It is thus possible to est. the phys. properties of a mixt. from a calorimetric detn. of the heat of swelling. That reinforcement depends upon free surface energy (contact surface tension δ multiplied by surface area of contact f) is supported by the fact that its temp. coeff. is of the same order of magnitude as the coeffs. of the surface tension of other 2-phase systems. Inherent difficulties in detg. A , may be avoided by testing the same filler in 3 degrees of fineness, where the relative surface areas are known fairly closely. There are 3 different values of U_0 , and f , n and m are the surface areas per g. (where only n and m must be known) and k is the fraction of U_0 which is equiv. to A_0 , then: (1) $\delta f = kU_0$; (2) $\delta n f = kU_0$, and (3) $\delta m f = kU_0$; in which δ is the unknown. With U in abs. units, δ is calcd. directly in dynes. The theory therefore allows the calcn. of the surface tension between rubber and fillers in general. One equation is sufficient for calcg. δ , since microscopic measurements give the abs. value of f , and k can be detd. by expt. from A . The smaller the heat of swelling of the rubber, the more precise can U be detd. With freshly milled rubber it was 0.1 cal. per g. in benzine, but after 9 months it was over 4 cal.; the great difference is probably caused by a heat of aggregation, corresponding to the increase in the work of rupture during storage. Swelling does not break up this aggregation, and after drying and swelling again rubber gives the same high value. By detg. calorimetrically k , U_0 and U of a filler, and A , by expt., it is possible to est. what proportion of the reinforcement results from the friction of the filler and what proportion from the surface energy, i. e., what part of the reinforcement is of the ideal type.

C. C. DAVIS

Chart for the estimation of equivalent cures. C. L. BRITTAI, Gutta Percha & Rubber, Ltd., Toronto. *Ind. Eng. Chem.* 21, 362-4(1929). A graphical method is described for evaluating and comparing cures under conditions where the rise and fall of temp. play an important part in the integral cure. It is not limited, like the method of Sheppard and Wiegand (cf. C. A. 22, 4272), to cures with a constant temp. rise, and where the intensity of curing action is a const. function of temp. The method evaluates precisely the curing effect of a variable temp. schedule, no matter how irregular. It is also reversible, i. e., a schedule with a certain desired curing effect may be obtained. There are 2 modifications of the method, depending upon whether abs. precision or an approx. result is desired.

C. C. DAVIS

Effect of antioxidants in typical rubber stocks. MARION C. REED, B. F. Goodrich Co., Akron. *Ind. Eng. Chem.* 21, 316-8(1929).—Natural and artificial latex tests of several different types of rubber mixts., including tire treads, inner tubes, foot-wear cured in dry air, sponge and steam hose, contg. the antioxidant "Agerite" are given. This substance improved the aging in all cases.

The accelerator "Tuads" and its imitations. FR. I. ÖBLEIN. *Kautschuk* 5, 38-9 (1929).—Comments on an article by Esch (cf. C. A. 23, 1526). Experience shows that "Thiuram" (a German com. grade of tetramethylthiuram disulfide) is quite similar to "Tuads" in its behavior as an accelerator.

C. C. DAVIS

Comparative investigations of Thiuram (a Vulcavit product) and Tuads. A. VAN ROSSEM. Staatl. Kautschukprüfungsamt, Delft. *Kautschuk* 5, 39-43 (1929); cf. preceding abstr. Analysis showed that "Thiuram" is purer than "Tuads," the latter contg. a trace of Mn and much higher ash and moisture contents. Comparative tests of their accelerating activities in different types of rubber mixts showed that in 2 cases the 2 products were virtually identical, while in another case the quality of the vulcanizate cured with "Thiuram" was superior. The relative tendencies to cause "scorching" were measured by keeping mixts at 100° and then measuring their hardness and their swelling in C₆H₆. Scorching was greater with "Tuads." "Thiuram" is considered superior to "Tuads."

C. C. DAVIS

Concluding remarks on the accelerator "Tuads" and its imitations. WERNER ESCH. *Kautschuk* 5, 62 (1929). Comments on articles by Öblein and by van Rossem (cf. preceding abstracts). It is considered that the data presented by the above authors show the superiority of "Tuads" over "Thiuram" rather than *vice versa*.

C. C. D.

Vulcanization and the structure of rubber. EUGENIO LINDMAYER. *Kautschuk* 5, 35-8 (1929).—The sulfurization and oxidation of oils and the vulcanization of rubber are explained in a hypothetical way by the aid of 3-dimensional space diagrams. No exptl. evidence is offered.

Treating rubber latex. P. MEYERSBERG. Brit. 295,600, Aug. 16, 1927. Natural or artificial latex is partially coagulated and rendered suitable for use in coating fabrics by adding weak org. acids such as rosin, elaine, stearic acid or linseed-oil acid, which react with the alkali which is present or which is added to form soaps. Fillers and disinfectants also may be added and if rosin is used it may be dissolved in colza or other suitable oil.

Improving the electric insulating properties of rubber products obtained directly from latex. K. D. P., LTD. Brit. 296,032, Aug. 23, 1927. The serum constituents are removed from latex, e. g., by dialysis, by the method described in German pat. No. 412,060, or by treating the latex with agglutinating agents as described in German pat. No. 442,856 and centrifuging.

Working up rubber. L. SZYNKOWSKI. Ger. 471,496, June 2, 1927. Crude natural rubber is cut up, given a short drying, and caused to swell by treatment with suitable hydrocarbons. The mass is then kneaded, filtered and worked up as usual.

Rubber compositions. ERNEST R. BRIDGWATER and AARON S. SLACK (to E. I. du Pont de Nemours & Co.). U. S. 1,705,712, March 19. In order to control the tendency of rubber to "scorch" or prematurely vulcanize during the necessary operations preceding vulcanization (such as dispersion of compounding ingredients with the rubber) and to improve the tensile strength and other properties of the rubber, it is incorporated

with a small proportion (suitably about 1-3%) of the reaction product of diphenyl-diaminomethane with stearic acid (or other suitable compd. formed by condensing 2 mol. proportions of a primary aromatic amine with 1 mol. proportion of an aliphatic aldehyde and treating the resulting diamine with a high aliphatic acid).

Thermoplastic rubber derivative. WILLIAM C. GEER and HERBERT A. WINKELMANN (to B. F. Goodrich Co.). U. S. 1,705,757, March 19. Rubber is incorporated with a softener such as pine tar and with concd. H_2SO_4 or other suitable isomerizing agent, and the mixt. is heated (suitably at a temp. of about 130° or higher) until it has assumed an inelastic thermoplastic condition and is then masticated to homogenize it.

Transformation products of rubber. THE B. F. GOODRICH CO. Fr. 646,414, Dec. 27, 1927. Conversion products of rubber are obtained by heating it with a phenol and one of the following: chlorinated rubber, rubber-HCl, rubber sulfur chloride, chlorinated rubber-HCl, pinene-HCl, diphenylamine-HCl, trichloroaniline-HCl, *m*-nitraniline-HCl, $HgCl_2$, $SnCl_4$, naphthalene tetrachloride, triphenylchloromethane, $ZnBr_2$, rubber dibromide, diphenylamine-HBr, $CaSO_4$, $Al_2(SO_4)_3$, $HgSO_4$, diphenylamine sulfate, diphenylamine trichloroacetate. Phenols include cresol, $PhOH$, catechol, resorcinol naphthols and *p*-chlorophenol. Several examples are given in which the temp. is kept at $134-160^\circ$ for 20 hrs. or longer.

Apparatus with an abrading drum for grinding or comminuting rubber. C. E. GARDNER. Brit. 295,434-5, May 12, 1927. Structural features.

Dipped rubber articles. E. HAZELL (to Naugatuck Chemical Co.). Brit. 295,700, Aug. 19, 1927. Deposition of rubber from latex on porous molds is accelerated by (1) diln., (2) addn. of substances increasing the rate of filtration of the aq. portion of the material through the deposit as it forms, (3) agitation, or (4) heating. For increasing the filterability, ZnO or a Zn salt and a sulfide such as that of Na, K, Li or NH_4 may be added. Various details of procedure are given.

Rubber articles from aqueous dispersions. P. KLEIN (to Anode Rubber Co. Ltd.). Brit. 296,107, Feb. 23, 1927. Rubber from aq. dispersions such as those formed from reclaimed or waste rubber is deposited by a continuous building-up process, upon a backing from which the product may be stripped either before or after subjection to vulcanization. The process may involve electrophoresis, suction or chemical action, and various details and modifications are described.

Forming vehicle bodies and associated parts of pliable "semi-hardened" rubber. A. LEVY-PICARD. Brit. 295,541, Dec. 21, 1927.

Synthetic rubber. I. G. FARBERIND. A.-G. Fr. 646,704, Jan. 4, 1928. Products of the nature of rubber latex are obtained by emulsifying butadiene, its homologs or analogs in water with the aid of emulsifying agents and polymerizing these emulsions with the addn. of buffers such as establish a pH value of 4 to 8.5. In examples, isoprene is emulsified with the addn. of NH_4 oleate and Na phosphates or Na oleate and Na isobutyl naphthalenesulfonate, or Turkey red oil and Na_2PO_4 , and heated for 2 or 3 weeks. The latex formed is coagulated by the addn. of $AcOH$, HCl , etc. Cf. C. A. 23, 2071. *

Vulcanizing rubber. MORRIS L. WEISS (to Dovan Chemical Co.). U. S. 1,705,948, March 19. Vulcanization is accelerated by use of a suitable substituted guan having 2 substituting aryl groups (at least one of the aryl groups being unsubstituted). Cf. C. A. 22, 1061.

Vulcanizing rubber boots. L. E. DE SANKTI-MAURO-GAEVSKII. Russ. Mar. 31, 1928. The usual vulcanization is carried out in an atm. of flue gases.

Vulcanization apparatus. THE AKRON STANDARD MOLD CO. Fr. 646,003, Dec. 13, 1927.

CHEMICAL ABSTRACTS

Vol. 23.

MAY 20, 1929

No. 10

1—APPARATUS AND PLANT EQUIPMENT

W. L. BADGER

A new automatic pipet. L. N. MARKWOOD. *Ind. Eng. Chem., Anal. Ed.* 1, 82 (1929).—Hot liquids may be measured without danger of cooling, and suction with the mouth is eliminated. The accuracy is quite good. J. H. MOORE

Standard-joint apparatus. J. FRIEDRICHS. *Chem. Fabrik* 1928, 725-6; 1929, 5-6.—Descriptions, with 50 cuts, of glass lab. app. with interchangeable ground joint. J. H. MOORE

An apparatus for the filtration of solutions, for precipitation and the filtration of these precipitates in a nitrogen atmosphere. V. GRAFE AND K. FREUND. *Neue Wiener Handelsakademie. Biochem. Z.* 205, 258-63(1929). S. MORGULIS

Receiver for vacuum distillation. EDGAR J. POTH. Univ. of Texas. *Ind. Eng. Chem., Anal. Ed.* 1, 111-2(1929).—An app. without stopcocks in the distn. train is described. J. H. MOORE

A continuous still for conductivity water. C. C. DEWITT AND GEO. G. BROWN. Univ. of Mich. *Ind. Eng. Chem., Anal. Ed.* 1, 109-11(1929).—Detailed direction is given for constructing and operating a continuous, practically automatic fractionating column. J. H. MOORE

Apparatus for the distillation of strongly foaming liquids. F. FRIEDRICHS. *Glas. u. App.* 9, 70(1928); *J. Soc. Glass Tech.* 12, 306(1928).—The fractionation of strongly foaming liquids such as soap soln. is possible, provided the spray from the bubbles of rising foam is caught in an efficient trap. In the app. illustrated a capillary air jet, A, impinges on the foam, and the minute spray, together with vapor, enters the mixing chamber, C, tangentially, where the swirling action centrifuges the spray to the sides, from which it drains back to the distn. flask, B, and allows the vapor to pass on by way of the centrally inserted exit tube, D. H. L. D.

Coated spiral fractionating columns. THOMAS MIDGLEY, JR. Thomas and Hochwalt Laboratories, Dayton, O. *Ind. Eng. Chem., Anal. Ed.* 1, 86-8(1929).—M. describes metal fractionating columns with spiral packing coated with carborundum dust. The spiral is coated with shellac, and air satd. with alc. is blown through to remove the excess shellac. Carborundum dust is then blown through the column and the carborundum sticks to the shellac binder. The columns have proved considerably better for sepn. than any other packing used. A single spiral column, a multiple spiral column and an adiabatic spiral column are described. These columns are metal and suited especially for lab. sepn. M. C. ROGERS

Centrifuges for the chemical industries. CARL SCHMITZ. *Chem. Fabrik* 1929, No. 6, 63-5.—Short descriptions are given of several centrifuges with details of construction and operation. C. Z. ROSECRANS

Performance of the gas centrifuge. WALENTY DOMINIK. *Przemysl Chem.* 11, 115-21(1927).—A mathematical paper. Theoretical sepn. of gaseous mixts. by centrifugal force into fractions of different compns. is quite possible. The centrifuge used by Mazza (*Power* 1926, 23) applied to gaseous mixts. made up of components of widely different densities should give technically pure gases. Size and % compn. of fractions can be changed by changing the radius of rotation at which the mixt. is introduced. A. C. Z.

A simple speed controller especially adapted to the moisture-equivalent centrifuge. F. J. VANMETER AND C. V. GRAY. *California Agr. Expt. Sta. Soil Sci.* 25, 455-60(1928).—The principal feature of this device is a steel reed. The operating circuit

of the speed controller is diagrammatically shown and also two figs. The app. is especially designed for soils.

A new extraction apparatus. ST. J. GAŠPERÍK. *Chem. Listy* 23, 58-9(1929).—

E. F. SNYDER

The app. consists of 4 parts: (A) a wide-mouthed flask with 3 indentations for supporting an extn. vial, (B) the extn. vial consisting of a wide tube with an inserted vertical tube which is protected by another larger tube, (C) a pressed celluloid filtering case which may be replaced by glass wool for some work and (D) a condenser. The material for extn. is placed in C and this is placed in B.

FRANK MARESH

Extraction apparatus for liquids. II. J. FRIEDRICH. *Chem. Fabrik* 1929, 90-1; cf. C. A. 22, 3553. —Comparative tests are given upon distns. and extns. with 4 types of app., including that with the porous glass plate previously reported they indicate the superiority of the new form of extn. app.

W. C. EHAUGH

Viscometer for small quantities of liquids. TADEUSZ RABEK. *Chem. Research Inst., Warsaw. Przemysl Chem.* 11, 614-9(1927). —This is an improvement of the Bonté-Bill viscometer (*Z. physik. Chem.* 53, 303(1905)). This app. requires only 5-6 cc. of the liquid, is simple and rugged in construction, and so sensitive to temp. that changes in viscosity, due to a difference of 0.05° can be detected. It is so easy to manipulate that as many as 50 measurements daily can be made with it.

A. C. ZACHLEY

A device for measuring surface tension automatically. LECOMTE DU NOUY. *Science* 69, 251-2(1929). In static measurements of surface tension on colloidal solutions it is essential to apply the pull very smoothly and slowly, increasing at the rate of about 20 dynes per min. The mols. disturbed by the deformation of the liquid surface thus have time to reorganize themselves in the surface layer. Consequently the "personal coefficient" of the experimenter plays a large part. An elec. motor drives the tensiometer knob at a rate to apply from 20 to 40 dynes per min. as desired. The motor current is cut off automatically when the ring tears loose, and a quick-acting brake is applied, thus reducing over-travel to practically zero.

C. Z. ROSECRANS

Ebullioscopic apparatus for investigations at high pressure. W. SWIENTOSLAWSKI. *Compt. rend.* 188, 392-5(1929). —An app. is described for ebullioscopic detns. modified to be run at pressures ranging from 8 to 25 atms. The original paper includes full details and 2 self-explanatory cuts.

ALBERT I. HUNGE

New modification of the ebullioscope adopted for high pressures. A. ZMACZENY. *Compt. rend.* 188, 395-6(1929). —An improvement of the app. described in the preceding abstr. The original paper includes a full description and a good cut.

A. I. H.

A self-regulating gas flowmeter. LYMAN CHALKLEY, JR. *Penn. State Coll. Ind. Eng. Chem., Anal. Ed.* 1, 74-5(1929). —The essential parts are an electrically operated gas valve, a flowmeter consisting of a capillary tube with a manometer connected across it, and means for operating the valve by changes in the manometer level. The app. gives good operation and control of gas flow.

M. C. ROEHS

Indication of measured values by light indices. H. SPRUNNA. *Chem. Technik* 1929, No. 5, 53. —A light-beam pointer device has been developed for switchboard or wall type instruments to be used in cases when it is desired to read the scales from some distance. The usual devices responsive to measured magnitudes are used, the light-beam device being applied to the responsive element, such as a vapor pressure thermometer for temp. measurements. One example given is a thermometer reading from 300° to 400°, with a scale 1.0 m. long, easily readable at a distance of 100m.

C. Z. R.

Apparatus for the determination of silicic acid in steel and iron by the chlorine process. P. DICKMAN. *Chem. Fabrik* 1929, 51-2. —The metal to be analyzed, iron or silicon for example, is heated to 900-1000° in a stream of dried Cl₂; it volatilizes and the silicic acid remains in the porcelain boat. Cl₂ is dried by concd. H₂SO₄; it is then passed through a porcelain tube at 900-1000° to burn out O₂. Final drying before passing into the combustion tube is by concd. H₂SO₄, CaCl₂, and P₂O₅. The whole app. is self-contained.

C. Z. ROSECRANS

Shaker for Clark hydrogen-ion electrode vessels. D. H. CAMERON AND ROSS SUGARMAN. *J. Am. Leather Chem. Assoc.* 24, 130-3(1929).

H. B. MERRILL

Automatic apparatus for determining the concentration of hydrogen ions. A. LAMMUN. *Ann. chim. anal. chim. appl.* 11, 66-71(1929); cf. C. A. 23, 734. —For

factory control of p_H values, the ballistic method for measuring e. m. f. can be used to advantage. In this paper an ingenious arrangement is described using the Carpentier model of the ballistic galvanometer such that one only has to start the app. and read the position of a luminous spot on a graduated scale. Thus, the p_H value of a liquid can be detd. without any manipulative skill. The values thus detd. are within about 7% of the truth.

W. T. H.

Tests of a new type of glass electrode. DUNCAN A. MACINNES AND MALCOLM DOLE. Rockefeller Inst. for Medical Research, New York. *Ind. Eng. Chem., Anal. Ed.* 1, 57-9(1929).—Great accuracy was obtained with electrodes with active glass surfaces only 0.001 mm. thick; also with active surface covering the ends of tubes only 0.75 mm. diam. They responded only to p_H concns. and were not influenced by oxidation-reduction potentials in the solns.

J. H. MOORE

New super-conductors. EDM. VAN AUBEL, W. J. DE HAAS AND J. VOOGD. *Proc. Acad. Sci. Amsterdam* 32, 218-25(1929).—See C. A. 23, 1544

E. C. M.

Apparatus for the determination of breakdown point of adsorbing systems. ANTON MACKERT. *Chem.-Ztg.* 53, 228(1929).—See C. A. 23, 1781.

E. C. M.

The fulgurator as an atomizer of salt solutions for flame spectra and the photography of its spark spectrum. WILHELM HIRSCHL. *Chem.-Ztg.* 53, 218-9(1929).—See C. A. 22, 1875.

E. C. M.

Evolution in conception of continuous furnaces and methods of heating them. A. HIRT. *Chaleur ind.* 9, 369-78(1928).—The first furnaces were for baking bricks; the fuel was added directly from above, as in the Hoffmann continuous furnace, with but fair results. Automatic feeding was then added and this improved combustion. For fine ceramic ware special furnaces were employed with a transverse grate working at 1300°. The primary air was regulated and good combustion was obtained. But the flame followed the air and there was a tendency to clinkering. This furnace was not tight and fuel consumption and labor were high. Intermittent ceramic furnaces often utilize external semi-gas firing. Primary air enters on the furnace grate and secondary air is heated by the cooling of products and by brickwork. Such furnaces require good coal, high in volatile matter. In the Faugeron furnace secondary air is heated by arches and has a zig-zag path; a low draft is required. Modern gas-fired furnaces have many advantages over coal furnaces. To bake a ton of refractory requires 500 m. of air for the combustion of the necessary coal, and 820 cu. m. are required for cooling off the same products. There is then an excess of air, which increases fuel costs and renders difficult the circulation of the product of combustion and produces uneven heating. H. considers better methods of heating in detail and gives temp. curves of the Hirt furnace. For furnaces requiring high temps. recuperators may be at the walls; waste heat app. may be installed. There are 18 diagrams with a discussion.

S. L. B. E.

Testing and rating of fuel-fired industrial furnaces. I. W. C. BUELL, JR. *Fuels and Furnaces* 6, 1505-14(1928).—Furnace tests may be either efficiency or balance tests. Percent efficiency of operation = B. t. u. absorbed by the product $\times 100$ / B. t. u. in the fuel. The balance test requires the heat data for input and distribution including stack losses, absorption by charge and radiation losses (this latter by difference). Proper allowance must be made for regenerators and for losses in ducts not an integral part of the furnace.

J. W. SHIPLEY

Steam drying oven with detachable base. HENRY J. S. SAND. Sir John Cass Tech. Inst., London. *J. Chem. Soc.* 1929, 214.—The base, or boiler section, of this oven is constructed as a sep. unit distinct from the rest, the junction between the 2 parts being made by a H_2O seal. Cleaning is thereby facilitated.

R. L. DODGE

Containers for caustic solutions. BYRON A. SOULE. Univ. of Mich. *Ind. Eng. Chem., Anal. Ed.* 1, 109(1929).—Bottles coated with Thermoprene, acid seal paint No. 1023 (B. F. Goodrich Co.), are satisfactory, at least up to 5 N solns.

J. H. MOORE

Elements of operation of the pneumatic table. ARTHUR F. TAGGART AND R. L. LECHMERE-ORRY. *Am. Inst. Mining Met. Eng., Tech. Publication* No. 196, 60 pp. (1929).—Results of an exhaustive series of expts. are shown. Several operating adjustments of an automatic table produce effects in the action of a given coal that may be grouped into two classes: stroke length, speed and rocker arm angle, which affect longitudinal travel; air supply and table slope (transverse and longitudinal), which det. transverse travel. The pneumatic table exerts, through the air supplied, a force on the articles upward away from the deck, but it lacks the positive control over cross travel which is supplied by the wash and feed waters. The paper is profuse with tables, charts and curves and explanations of results. "Pneumatic table practice has suffered from the effects of the assumption that the action on the table is the same as or closely similar to that on the deck of wet shaking tables."

W. H. BOYNTON

Heavy-duty thermostat. D. F. ORINGER. Univ. Mich. *Ind. Eng. Chem., Anal. Ed.* 1, 97(1929).—The app. is simple and rugged; it is designed to control at least 4000 w. of elec. energy and to hold the temp. of a small boiler const. to 0.02°. J. H. MOORE

A note on the Haughton-Hanson thermostat. A method of fine adjustment. P. J. DURRANT. Selwyn Coll., Cambridge. *J. Inst. Metals* (advance copy), No. 496, 4 pp.; *Engineering* 127, No. 3296, 327; *Metal Ind.* (London) 34, 315-6(1929).—The "cold bulb" of the H.-H. app. is held at a const. temp. by inserting a small toluene thermostat by means of which the temp. of the app. can be adjusted over a range of about 5° with an accuracy of 0.1°. Directions are given for varying the temp. or adjusting it to any desired point. J. H. MOORE

Use of crystalline quartz for spectrographic work (ELLIS) 3. Ostwald color theory (SACHS) 2. Leading-in wires of electric lamps, etc. (Brit. pat. 296,453) 4.

and Industrial Instruments. A catalogue of Negretti and Zambra. London, 38 Holborn Viaduct: Negretti and Zambra. 460 pp. Reviewed in *Chem. Trade J.* 84, 290(1929).

Wien-Harms Handbuch der Experimentalphysik. Band XIII. Teil 2. Glühelctroden und technische Elektronenröhren. Leipzig. Akad. Verlagsgesellschaft m. b. H. 492 pp. Bound, M. 46. Reviewed in *Science Progress* 23, 708(1929).

Adjustable clamp suitable for laboratory uses. CHARLES H. BONE. U. S. 1,754, April 2.

Thermocouple pyrometer. G. E. LLOYD and ELECTROFLO METERS CO., LTD. Brit. 297,261, Dec. 23, 1927. Structural features.

Filter. C. S. GARLAND. Brit. 296,359, May 30, 1927. A filter surface is formed of helically woven wire or strip-like mesh supported so that it can be stretched longitudinally and the area of the meshes extended or contracted to give a greater or less degree of permeability. Various structural features are described.

Filters. ÉTABLISSEMENTS SIMONETON (S & R. L.). Fr. 647,095, May 21, 1927. The filters are formed as hollow disks rotating on a hollow axle into which the liquid flows.

Filter for use with zeolites. WERNER NEUMANN. U. S. 1,708,704, April 9. Structural features.

Air filter. JULES L. E. ROUBAUD. Fr. 647,174, June 3, 1927. An arrangement of vertical metallic sheet filter elements is described.

Filter for air or other gases. ANDERS JORDAHL and KARL G. RUNBACK (to Mid-west Steel & Supply Co.). U. S. 1,708,065, April 9. Structural features.

Oil filter. WILLIAM W. NUGENT. U. S. 1,708,517, April 9. Structural features.

Sand filters. LOUIS E. RAINBERRY. Fr. 33,624, May 31, 1927. Addn. to 628,112. Constructional features. The celluloid cylinders are replaced by Pb or ceramic cylinders for filtering concd. acids.

Overflow-alarm device for filtering apparatus. WILLIAM W. NUGENT. U. S. 1,708,235, April 9. An elec. bell alarm is provided on filtering app. such as that used for filtering oil.

Filter drum. EUGEN GEIGER. Ger. 472,181, Aug. 5, 1926.

Apparatus for the continuous separation of suspended matter from liquids or gases. FRIEDRICH BARTLING and FRANZ LAWACZECK. Fr. 647,754, Dec. 30, 1927.

Device with truncated conical baffles for separating dust from air or other gases. HENRY R. DAVIES (to Industrial Research Corp.). U. S. 1,708,122, April 9.

Tank and baffle-plate construction for separating oil from water by gravity. S. LAUZ and GEORGE E. JUPP (to American Marine Device Corp.). U. S. 1,708,122, April 9.

Centrifuges. AKTIEBOLAGET SEPARATOR. Fr. 647,923, Jan. 28, 1927. The method of removing the liquid is described.

Centrifugal apparatus for purifying oils, etc. AKTIEBOLAGET SEPARATOR. Brit. 296,670, Sept. 3, 1927. Brine may be used periodically for removing solid impurities deposited in the app.

Plant for centrifuging liquids. KARL J. SVENSSON and KARL A. P. NIELING. Ger. 472,083, Nov. 30, 1926. The plant comprises a centrifuge, a feeder, 1 or more elec. preheaters and containers for washing liquid and for the products.

Means for lifting and tilting centrifuge drums. KARL J. SVENSSON and KARL A. P. NIELING. Ger. 472,034, Oct. 8, 1926.

Röntgen-ray apparatus. A. DEMBLON. Brit. 296,733, Sept. 6, 1927.

X-ray tube. GUSTAV BUCKY. U. S. 1,708,494, April 9. Structural features.

Thermionic valves. ALLOEMEINE ELEKTRICITÄTS-GES. Brit. 297,332, Sept. 17, 1927. An auxiliary electrode is arranged near a highly emitting or low-consumption cathode so as to collect pos. ions and to prevent deterioration of the emitting properties of the cathode. Various structural and elec. features are described.

Thermionic valves. COMPAGNIE FRANÇAISE POUR L'EXPLOITATION DES PROCÉDÉS THOMSON-HOUSTON. Fr. 647,096, May 24, 1927.

Photoelectric cell. ALBERT B. PAGE (to General Electric Co.). U. S. 1,708,773, Structural features.

Cathodes for photoelectric cells. SIEMENS-SCHUCKERTWERKE A.-G. Ger. 472,485, Jan. 29, 1927. The cathodes are formed from a mixt. or alloy of an alkali metal with another substance selected so that the mixt. or alloy has a higher m. p. than the alkali metal. A suitable compn. comprises K 90-95% and Ba 10-5% and may be prepd. by bringing the metals together in an evacuated vessel at a very low temp. and heating the mixt. to above its m. p.

Ionization chamber for radiation measurement. SIEMENS & HALSKE A.-G. Ger. 472,110, Mar. 29, 1925. An ionization chamber of the "thimble" type is constructed with an inner C electrode of a diam. at least equal to the width of the gas layer between the electrodes.

Low-pressure metallic vapor-containing electric discharge devices. J. W. MARDEN and E. A. LEDERER (to Westinghouse Lamp Co.). Brit. 296,781, Sept. 9, 1927. Metals, such as the alkali metals, are introduced into evacuated or gas-filled containers, such as electron discharge devices, by mixing a compd. such as $\text{Cs}_2\text{Cr}_2\text{O}_7$ or CsMnO_4 with a finely divided metalloid such as Si or B and effecting reduction inside the container. The $\text{Cs}_2\text{Cr}_2\text{O}_7$ and CsMnO_4 can be freed from moisture and the metalloids rendered gas-free by boiling in dil. HCl until evolution of gas ceases. The use of CsMnO_4 is preferred as O is evolved before the alkali metal is liberated; this O serves for oxidation of the filament. The temp. at which the Cs salt is decomposed is stated to be about 900° but may be reduced to about 700° by the addn. of about 1% of pure, grease-free, finely powdered Al or Al filings.

Furnace of the type in which substances to be heated are passed continuously. ARTHUR DE BOUW. Fr. 647,471, Jan. 19, 1928.

Cupola furnace with slag separator between forehearth and shaft. OTTO KIPPE. Ger. 472,139, July 12, 1925. Addn. to 431,628.

Annealing furnace. SIEMENS ELEKTROWÄRME-GESELLSCHAFT M. B. H. Fr. 33,605, May 25, 1927. Addn. to 612,730.

Annealing or tempering furnaces. AKTIEN GESELLSCHAFT, BROWN, BOVERI & CIE. Fr. 647,727, Nov. 7, 1927.

Muffle furnace for vitreous enameling, annealing, etc. GIBBONS BROS., LTD., and T. E. BRIDGFORD. Brit. 296,936, Jan. 4, 1928. Structural features.

Reduction furnace. JEAN SAUVAGEOT. Fr. 647,354, Jan. 10, 1928. A thin barrage of combustion gas is created across the hearth behind the furnace door to prevent entry of air when the door is opened.

Bakery furnaces using mazout. HENRI HERSANT. Fr. 33,397, April 21, 1927. Addn. to 615,217.

Furnace-roof construction. HENRY W. SPENCER. Fr. 647,900, Jan. 24, 1928.

Apparatus for charging tilting smelting furnaces. JOSEF E. GERLACH. U. S. 1,707,937, April 2.

Regulator for _____ ary air supply to furnaces. NICHOLAS HENNESSY. Fr. 647,297, Dec. 16, 1927.

Burners for gas furnaces. HILARION ROUSSET. Fr. 33,518, Feb. 2, 1927. Addn. to 579,369.

Gas burner. JOHN V. THOMAS and BEN D. BALTHIS. U. S. 1,707,451, April 2. Structural features.

Air regulator for gas burners. ÉTIENNE GHIO and ÉMILE P. L. LE BARBIER. Fr. 647,480, Jan. 19, 1928.

Burner for gaseous and powdered fuel. DEUTSCHE BABCOCK & WILCOX DAMPF-KESSEL-WERKE A.-G. Ger. 472,411, Mar. 31, 1925. The fuel mixt. is introduced into a side slit burner tube in 2 regulable, oppositely directed streams. The intensity and incidence of the heating are controlled by adjusting the pressure of 1 or both of the streams.

Burner for powdered fuel. CARL HOLD. Ger. 472,412, April 2, 1924. The combustion chamber is pear-shaped, the fuel-air mixt. entering under slight pressure or

suction at the top and the combustion products passing out through conduits at the side.

Feeding powdered coal to burners. BERG & CO. GES. FÜR INDUSTRIE-OFFENBAU U. FEUERUNGSBEDARF M. B. H. Fr. 648,008, Jan. 31, 1928.

Coal-dust burner. DEUTSCHE BABCOCK & WILCOX DAMPFKESSEL-WERKE A.-G. Ger. 472,185, April 28, 1926. Improvements are described in a burner of the kind in which radial plates impart a whirling motion to the air-fuel mixt.

Atomizing burner for liquid fuels. EDWARD J. Y. RUTHERFORD. Ger. 472,480, July 25, 1925. Steam for atomizing the fuel is generated in a special flash boiler. See Brit. 237,203.

Burner for liquid fuel such as coal-tar oil or mazout. ALBERT B. FOURNIEN. Fr. 647,517, Jan. 20, 1928.

Burner for liquid fuel such as mazout. AUGUSTE CHANARD. Fr. 647,190, June 4, 1927.

Oil burner with a number of differently directed atomizers. ATELIERS H. CUÉNOD S. A. Ger. 472,213, April 14, 1927.

Burner for oil and air under pressure. WILLIAMS OIL-O-MATIC HEATING CORP. Ger. 472,490, Oct. 8, 1926. A valve in the conduit to a gas igniter is held open by a membrane susceptible to the pressure of the fuel mixt. so long as the pressure remains in a given range.

Heat exchanger, especially for preheating air for combustion. NILS R. FORSSBLAD. Ger. 472,071, Feb. 1, 1925.

Heat-exchange apparatus suitable for use as a condenser-type heater. JOHN P. RATHBUN (to Westinghouse Elec. & Mfg. Co.). U. S. 1,708,031, April 9.

Heat-exchange apparatus suitable for heating air or gas supplied to blast furnaces. FREDERICK H. WILLCOX and JOHN C. HAYES, JR. U. S. 1,707,777, April 2. Structural features of a flue system, etc., are described.

Apparatus for control of heating apparatus, etc. RICHARD P. BROWN (to Brown Instrument Co.). U. S. 1,707,652, April 2.

Portable electrically heated steam superheating device. ALEXANDER VINOGRADOV. U. S. 1,707,453, April 2. Structural features.

Kilns. NICOLA LENGERSDORFF. Ger. 471,772, May 5, 1925. A gas heated kiln has 2 parallel heating chambers.

Continuous, multiple-chamber downdraught kiln construction. E. G. SPENCER-CHURCHILL. Brit. 296,844, June 29, 1927.

Gas-analysis apparatus. SVENSKA AKTIEBOLAGET MONO. Ger. 466,553, Aug. 29, 1925. Gas-analysis app. is described, particularly for flue gases, of the kind in which an oscillating Hg column draws a sample of gas into the app. and then forces it through an absorption liquid into a measuring bell. The absorption liquid is used to effect the movement of the Hg and to seal the bell.

Container for gases under pressure. PAUL BENKOWITZ. Ger. 472,059, Aug. 2, 1927. See Brit. 294,943 (C. A. 23, 1785).

Receptacles for holding carbon dioxide under high pressure. H. R. MINOR. Brit. 297,270, Jan. 16, 1928. The receptacles are provided with a safety disk of thin Cu or phosphor bronze and a pliable protective shield to conform with the shape of the disk and to resist any corrosive effects of the gas. The protective shield may be of thin celluloid or the disk may be plated with Au.

Containers for storing and transporting liquid gases of low boiling point. STUDIEN GESELLSCHAFT FÜR GASINDUSTRIE M. B. H. Fr. 647,272, Nov. 12, 1927.

Apparatus for treating liquids with other gases to remove air preliminary to irradiation of the liquid. H. SCHOLL. Brit. 297,086, Sept. 14, 1927. An app. is described suitable for use in processes such as described in Brit. 283,472 (C. A. 22, 4015). Brit. 297,088 also relates to deaerating and irradiating app. for treating liquids.

Gas-comparison apparatus for thermal conductivity comparisons. RICHARD P. BROWN (to Brown Instrument Co.). U. S. 1,707,624, April 2.

Combined gas washer and ventilator. FIRMA EDUARD THEISEN. Ger. 472,182, May 4, 1926. Addn. to 387,526.

Gas-washing apparatus (with intermeshing stationary and rotating baffle devices). HERMAN A. BRASSERT, CHARLES E. DOUGAN and EDMUND VON MALTITZ (to H. A. Brassert & Co.). U. S. 1,707,548, April 2.

Apparatus for producing gas from "petrol" or similar volatile liquids. LUCIEN BROCAUT. U. S. 1,707,249, April 2.

Glass spirals. MILOŠ KLAVIK. Ger. 472,315, Oct. 28, 1926.

Catalytic app. THE SILDEN CO. Fr. 647,770, Jan. 19, 1928. A catalytic

app. comprises at least one converter provided with cooling means, which enables it to work above normal output rate, and a converter of much less cooling capacity. Coolers or heat exchangers may be used between the two. A series of converters of progressively decreasing cooling capacity may be used and the strongly cooled converters may be designed so that the cooling is proportional to the rate of gas flow, this being obtained by passing the incoming gas through heat-exchangers embedded in the catalyst. Cf. *C. A.* 23, 1024.

Apparatus for carrying out reactions under pressure. JACQUES L. H. HUGUES and JEAN M. P. BLANDIN. *Fr.* 647,338, Jan. 5, 1928.

Still with a rotating heated pipe system dipping into the liquid. W. RUNGE (to Coal Oil Extraction, Ltd.). *Brit.* 296,430, Sept. 2, 1927.

Concentrating and dehydrating apparatus. CECIL F. HAMMOND and WM. SHACKLETON. *Fr.* 647,472, Jan. 19, 1928.

Apparatus for spray desiccation of liquids. B. F. UHL (to Industrial Spray-Drying Corp.). *Brit.* 296,421, Sept. 1, 1927.

Use of an atomizer for effecting chlorinations or other reactions. H. T. BUCHERER. *Brit.* 296,376, Aug. 30, 1927. Gas and liquid conduits of an atomizer device are calibrated and pressures are adjusted to secure the desired proportions of liquid and gaseous reagents in chlorination of org. liquids, in treating liquid S with air, in treating liquid bases with gaseous acids or other reactions.

Drying apparatus for casein and other powdered substances. GEORGES LIGRAUD. *Fr.* 647,911, Jan. 27, 1928.

Drying apparatus for casein and the like. HERMANN ALBERT AUDEMARS. *Fr.* 635,507, Jan. 26, 1927. Addn. to 626,978.

Extraction plant for sugar and other substances. ANCIENS ÉTABLISSEMENTS EGROT ET GRANGÉ. *Fr.* 647,239, June 8, 1927.

Air cooler. MASCHINENFABRIK CARL WIESSNER KOMM-GES. *Ger.* 471,543, Aug. 5, 1926. A wet air cooler with superposed stages has a no. of irrigating nozzles in the air current in each stage, corresponding to the position of the stage.

Device for indicating the carbide supply in an acetylene-generating system. EMIL MENZ. *Ger.* 471,781, Nov. 19, 1927.

Impact device for testing hardness of materials. DONALD C. DAVIS. *U. S.* 1,708,262, April 9. Structural features.

Wedge photometer apparatus for observing the color or turbidity of fluids. WILLIAM G. EYTON. *U. S.* 1,707,717, April 2.

Stand for calorimetric bombs. JAMES DARROCH. *U. S.* 1,708,754, April 9. Structural features.

Apparatus for holding and controlling the supply of liquid carbon dioxide, etc., for fire-extinguishing. D. MARAS (to W. Kilde & Co.). *Brit.* 296,404, Aug. 31, 1927.

Bubble-cap absorption tower suitable for absorption of nitrogen oxides. GUY B. TAYLOR (to E. I. du Pont de Nemours & Co.). *U. S.* 1,708,685, April 9. Structural features.

Porous metallic plates or objects, particularly for storage batteries and the like. A. GRÉGOIRE. *Belg.* 351,859, July 31, 1928. A granular metallic mass is heated in a mold so as to sinter it, thus causing partial coalescence at the points of contact.

Thermostats. WESTINGHOUSE ELECTRIC AND MANUFACTURING CO. *Fr.* 647,304, Dec. 21, 1927. The metal of low coeff. of expansion (A) is an alloy contg. Fe and Ni, while the metal of high coeff. of expansion (B) is an alloy contg. Fe and Mn. If (B) contains 10% Mn and 10% Ni, (A) contains 38-45% Ni, and if (B) contains 38% Ni and 4.6% Mn, (A) contains 42% Ni.

Thermostatic valve-control device. J. P. MORLEY and S. J. LONERGAN (to Bastian-Morley Co.). *Brit.* 296,973, Sept. 10, 1927. A device is described suitable for controlling gas burners used for heating water.

Thermostatic device for controlling electric heating devices. EARL K. CLARK (to Westinghouse Elec. & Mfg. Co.). *U. S.* 1,707,253, April 2.

Thermostatic or pressure control of fuel supplied to steam generators, etc. C. W. PATTISON. *Brit.* 297,148, June 16, 1927.

Thermostatic cut-off for gas burners. EDWARD A. KLEGA (one-half to George H. Stucke). *U. S.* 1,708,446, April 9.

Thermostatic and pressure-controlled valve mechanism suitable for control of gas burners of water heaters. JOHN H. KOLTA (to Pittsburgh Water Heater Co.). *U. S.* 1,708,508, April 9. Structural features.

2—GENERAL AND PHYSICAL CHEMISTRY

FREDERICK L. BROWNE

Jan Novák (1881-1929). V. ČECH. *Chem. Obsor* 4, 65-7(1929).—A biographical sketch with portrait.

The seventieth birthday of Hermann Thoma. K. W. ROSENMUND. *Z. angew. Chem.* 42, 273-4(1929).—Biographical note with portrait.

The twenty-fifth anniversary of the foundation of the chemical society of Holland and the ninth meeting of the International Union of Pure and Applied Chemistry. J. GIRAL AND O. FERNÁNDEZ. *Anales soc. españ. fís. quim.* 27, 32-42(1929).

Nobel prize in chemistry for 1927 and 1928: H. Wieland and A. Windaus. K. JOSEPHSON. *Svensk. Kem. Tids.* 40, 300-4(1928).—A brief sketch with portraits.

The recent Nobel prize winners in chemistry. ANON. *Tekniska Föreningens i Finland Förhandlingar* 49, 30-2(1929).—Biographical sketches of Adolf Windaus and Heinrich Wieland.

We demand system even in the realm of literature. KUTZNER. *Chem. Technik* 1929, 1-2.—A plea for better technical articles. Black type, paragraphing and headings save the searcher's time. In describing new apparatus points to be covered are, in order, purpose, applications already made and results obtained, manner of operation, labor and supervision needed, quality of product, size and weight of app., output, space requirement, motive power, heat and power consumption, probable repairs, construction in detail (with exact drawings), material used, patent information and other possible uses. New materials should be compared with similar known ones; phys. and chem. properties, uses, handling, working and forming should be described and full patent information given.

The nomenclature of high-school chemistry. J. O. FRANK. State Teacher's College, Oshkosh, Wis. *J. Chem. Education* 6, 72-5(1929).—A long study of high school texts shows that many almost useless new terms are used, that teachers are careless in the use of terms, that different authors use different terms for the same thing, that the special chem. meaning of terms like "normal," "condenser" are not explained and that definitions are often either avoided or incorrectly given.

Significance of symmetry in chemical combination. S. H. C. BRIGGS. *Chemistry and Industry* 48, 108-9(1929).—A plea for the retention of the words "molecule" and "coordination" in their original meaning and not merely in the restricted sense in which they are now being used by the protagonists of the electron theory of valency.

The rigidity and viscosity of nickel at the Curie point. T. GNESOTTO AND L. A. ALBERTI. *Atti ist. Veneto* 87, Part II, 735-56(1927-8).—From an examn. of the rigidity and viscosity of Ni at different temps. it is concluded that a fundamental change takes place at the Curie point which affects both the microstructure of the metal and the crystal structure itself.

Does pure iron have allotropic transformations? T. D. YENSEN. Research Lab. Westinghouse Elec. and Mfg. Co., East Pittsburgh, Pa. *Science* 68, 376-7(1928).—If α -Fe contains in soln. such impurities as C and O in excess of their soly. for the given temp., either the impurities will be pptd. or the Fe will change into the γ form. Si prevents this transformation, the amt. required being proportional to the C content. Assuming the absence of O, and extrapolating to zero C, the Si content necessary to eliminate the transformation should also be zero. That is, pure Fe can exist in the α form only. Equil. diagrams based on this hypothesis are in accord with exptl. evidence.

Allotropic modifications and solid solutions of phosphorus. V. I. NIKOLAEV. *J. Russ. Phys.-Chem. Soc.* 60, 1045-51(1928).—Four allotropes of P exist, viz., white phosphorus, d_{4}^{25} 1.82, ignition point (i. p.) 55°; purple, d_{4}^{25} 1.90, i. p. 200°; ruby red, d_{4}^{25} 2.11, i. p. 345°; and black, d_{4}^{25} 2.70, i. p. about 490°. At d. intermediate to the above a continuous series of solid solns. exists, in which the colors are also intermediate. Red phosphorus is a solid soln. of the ruby-red and the purple forms, while violet phosphorus consists of ruby-red and black phosphorus.

Magnetic susceptibility of ozone. V. I. VAIDYANATHAN. *Indian J. Physics* 3, 151-65(1935); cf. *C. A.* 22, 4349.—Expts. were made on mixts. of O₃ and O₂ by the rotational method, in which the gas surrounds the test-rod system. Errors due to current fluctuations, temp. changes, etc., were eliminated as far as possible. In every case the

magnetic force on the mixt. was less than that for pure O_2 . The possibility that O_2 is paramagnetic, as reported by some previous investigators, is discussed in some detail. On the basis of statistical probability as applied to the present series of expts. it is concluded that O_2 is definitely diamagnetic.

W. W. STIFLER

Diamagnetism and structure of ethylene. V. I. VAIDYANATHAN. *Indian J. Physics* 3, 165-74(1928).—Tests on C_2H_4 by the torsion method indicate that it is diamagnetic with a mol. susceptibility of -15.3×10^{-6} , not paramagnetic as reported by Lewis and by Quincke. It is shown that this is in fair agreement with Pascal's additive law. Various possible structures for the C_2H_4 mol. are discussed. W. W. S.

Electric moments of methyl chloride, ethyl chloride and chloroform. S. C. SIRCAR. *Indian J. Physics* 3, 197-208(1928).—By using the heterodyne beat method the dielec. consts. of the vapors of CH_3Cl , C_2H_5Cl and $CHCl_3$ were measured at several temps. between 20° and 100° and at pressures between 68 and 196 mm of Hg. The results agree with Debye's dipole theory. The permanent dipole moment for CH_3Cl is 1.69×10^{-18} e.s.u., which is in excellent agreement with the value 1.66×10^{-18} deduced from optical data. For C_2H_5Cl the present work gives 1.98×10^{-18} , while optical data give 1.76×10^{-18} . This disagreement is ascribed to the assumption made in the optical calcn. that the angle between the A axis of the optical anisotropy and the permanent moment is zero. For CH_3Cl the moment calcd. is 1.05×10^{-18} ; Sanger gives 0.95×10^{-18} .

W. W. STIFLER

Electric moment and its relation to chemical constitution. P. C. MAHANTI AND D. N. SEN GUPTA. *Indian J. Physics* 3, 181-96(1928).—The dielec. consts. of several org. halides were measured by a heterodyne beat method. From these results the following values are calcd. for the permanent dipole moments according to Debye's theory: CH_3I , 1.31×10^{-18} e.s.u.; C_2H_5Br , 1.78×10^{-18} ; and C_2H_5I , 1.62×10^{-18} . The corresponding values for the polarizability are 0.005761, 0.002200 and 0.007839, resp. Hence, in these compds., increasing at wt. of the halogen seems to be accompanied by weakening dipole moment. The permanent dipole moment seems to be due to a deformation of the electron orbits of the C and the halogen. The weakening of the bond of the shared electron as the at. wt. of the halogen increases is suggested to explain the increase in polarizability which accompanies it.

W. W. STIFLER

Studies of dipole-moment. KRISTIAN HØJENDAHL. Separate 1928, 160 pp.—The fundamental laws of Debye's dipole theory are discussed in detail. The pos. charges in the mol. and the electrons are considered as coned at 2 points, corresponding to their resp. "centers of gravity." The product of the distance between these points by the charge at either one is the dipole-moment of the mol. When placed in an elec. field, dipole mols. acquire an induced moment, because of orientation by the field, but this orientation is counteracted in part by the thermal agitation. Hence the induced moment and dielec. const. are dependent on the temp. as well as upon any deformation produced in the mol. A derivation is given for the Clausius-Mosotti equation and the induced moment is expressed in terms of the dielec. const. By the Lorenz-Lorentz equation the effect of the electron shift on the induced moment is expressed in terms of the n . The mol. polarization is considered to be made up of 3 parts, viz., mol.-electron, mol.-atom and mol.-orientation polarizations. The mol.-electron polarization is identified with the mol. refraction in the infra-red. For dil. solns. in non-polar solvents, or in the gaseous state, there is little assocn. of the solute mols. The mol.-atom polarization is negligibly small for this case. Hence the mol.-orientation polarization can be calcd. as the difference between mol. polarization and the mol.-electron polarization as given by optical data, and from this result the dipole-moment can be computed. The value obtained in this way is shown to be independent of the nature of the non-polar solvent. The relation between dipole-moment and structural formula is discussed, the data of various investigators being used. Since the dipole moment is approx. const. for a no. of univalent Alcs. it is suggested that the dipole-moment is a property of the polar group, and the group-moment is assumed equal to the dipole-moment of the mono-substituted hydrocarbon compd. Since dipole-moment is, by definition, a vector quantity, the dipole-moment of a mol. contg. 2 polar groups is the geometric sum of their individual moments. Since a single bond permits free turning, the angle between 2 polar groups joined by a single bond may be altered. Hence such a "pliable" mol. has no fixed dipole-moment. If a mol. possesses central symmetry, the vector sum of the moments is zero, and hence, if the mol. is rigid, the dipole-moment vanishes. Conversely, the vanishing of the dipole-moment for mols. contg. several polar groups indicates central symmetry. For such mols. the mol. polarization is independent of the temp., and the dielec. const. approx. so. Also, Maxwell's law holds approx., viz., that the dielec. const. equals the square of the n . The third section gives the details of H.'s exptl. in-

vestigations. Density, dielec. const. by a resonance method and n were measured for several solns. in benzene of each of a no. of org. compds. It was found that the vector-addition rule does not hold for the nitroanisoles and the nitroanilines. It is suggested that, at least for the nitroanisoles, this may indicate that the mol. is pliable, but this explanation cannot hold for the nitroanilines. In addn. to H.'s own results, dipole-moments are computed from Pohrt's data. The dipole-moments published up to 1928 are collected into a table filling 6½ pp., including 1 p. of inorg. compds. A bibliography of 210 items on dielec. consts. and dipole-moments is given and a table of the functions of Clausius-Mosotti and Lorenz-Lorentz is included. A no. of the most recent papers (1928) are discussed in the appended notes. W. W. STIFLER

Dielectric constant of superfused sulfur and of several sulfur solutions. STEFAN ROSENTHAL. Cracovie Univ. *Bull. intern. acad. Polonaise* 1928, 377-95.—The d. and the dielec. const. of superfused S were detd. between 150° and 95°. Liquid S, even superfused S, obeys the Clausius-Mosotti law; there are no elec. doublets. When S solidifies the dielec. const. increases very suddenly. The ds. and dielec. const. of several solns. of S in C₆H₆ and CS₂, and those of pure CS₂ were measured. All obey the Clausius-Mosotti relation. The polarization of the solns. investigated can be calcd. from those of S and its solvents by the Lorenz-Lorentz formula for mixts. A. I. H.

Magnetic properties in relation to chemical constitution. T. M. LOWRY AND F. L. GILBERT. *Nature* 123, 85(1929).—A no. of compds. to which formulas with single electron bonds have been assigned were examd. magnetically. With the exception of those contg. a metal of the transition series, all were found to be diamagnetic. Hence it is concluded that all the electrons are magnetically paired. HgCl, CuI and HgCl₂ are diamagnetic but CuCl₂ is strongly paramagnetic. The diamagnetism of HgCl is explained by the formation in soln. of the Hg⁺ ion. This is confirmed by x-ray analysis of crystals of calomel which indicates the presence of mols. of the formula Cl-Hg-Hg-Cl. Hence in mercurous salts the metallic atoms contain completed shells of 18 unshared O-electrons. The behavior of CuI indicates that cuprous salts contain only univalent metallic ions. But since CuS is diamagnetic like Cu₂S, it is suggested that the formula

may be in reality CuS— $\dot{S}\dot{C}u$.

W. W. STIFLER

The chemical union (valence) as an electrostatic phenomenon. A. E. VAN ARKEL AND J. H. DE BOER. *Chem. Weekblad* 26, 66-9, 114-8(1929).—An exposition of the modern conceptions of chem. valence, including the Bohr model of the atom, the periodic table derived therefrom and the configuration of ions. G. CALINGAERT

The constitution of high-molecular substances. H. STAUDINGER. *Naturwissenschaften* 17, 141-4(1929); cf. *C. A.* 23, 822.—A review of the work of S., in which it has been shown principally from work on synthetic "models" of high-mol. substances, that these are to be considered as actual chem. mols., not as micellae. Numerous references are given. B. J. C. VAN DER HOEVEN

Magnetic permeability of nickel in feeble oscillatory fields. R. G. LOVARTY. *Univ. Nac. La Plata, Estudio Ciencias* 1928, 209-16; *Science Abstracts* 31A, 501. Several authors have suspected a very pronounced max. in the magnetic permeability of Fe for feeble oscillations of a wave length of 100 m. but the work of Wait has shown the effect to be spurious. L. therefore exams. the result announced by Israel according to which the permeability of N shows a complicated structure between the wave lengths of 28 and 60 cm. He shows that it is also false and is due to the dependence of the damping upon the period. H. G.

The Kerr constant of nitrobenzene. R. MÖLLER. Hamburg Inst. angew. Physik *Physik. Z.* 30, 20-4(1929).—Nitrobenzene has the largest Kerr const. among liquids. Hence it is used in phototelegraphy, etc. Values given by Schmidt (1902), Leiser (*Abh. Bunsen-Ges.* No. 4 (1910)), Lippmann (Dissert. Leipzig, 1912), McComb (*Phys. Rev.* 29, 525(1909)), Lyon (Dissert. Freiburg, 1914), Szivessy (*Z. Physik* 2, 30(1920)) and Ilberg (*C. A.* 23, 339) do not agree; hence the present work. The chief difficulty is to obtain nitrobenzene of low enough cond. The nitrobenzene was distd. and kept *in vacuo*. M. concludes that the impurity in the nitrobenzene behaves as an electrolyte which deposits and has a different transformation velocity. If the field strength is too small, low values are obtained for the Kerr const. Lyon's value is too large, $B = 4.43 \times 10^{-4}$. The values of McComb and Szivessy and Ilberg are too small. What is now required is to obtain nitrobenzene of still lower cond., to improve the photographic appliances and to use these at higher field strengths. S. L. B. ETHERTON.

Ostwald color theory. ALBERT P. SACHS. *Instruments* 2, 53-5, 85-9(1929).—Description of Ostwald's color theory and of photometric app. WALLACE R. BRODE

A technic for the examination of crystal structures with many parameters. W. L.

BRAGG AND J. WEST. *Z. Krist.* 69, 118-48(1928). (English.)—This paper summarizes the recent developments in the technic of making direct detn. of complex structures such as found in the silicates. Although use is made of certain assumptions, such as the type of symmetry, the existence of at. groups, the probable dimensions of atoms, etc., for help in the preliminary detn., the final proof of structure can be based on abs. measurements.

L. S. RAMSDELL

The influence of crystal habit on Debye-Scherrer diagrams. J. BÖHM AND F. GANTER. *Z. Krist.* 69, 17-25(1928).—Variations in habit, such as are found in fibrous or foliated substances, may affect the breadth of the lines in the x-ray diagram, and may also change the relative intensities. This latter may be because reflections from certain planes have to pass through a greater thickness of material, or because of preferred orientations. With chalcotrichite (a variety of cuprite with elongated cubic fibers) the reflection from 001 is practically lacking, and the intensity of the line is contributed to only by 100 and 010.

L. S. RAMSDELL

The theory of liquid crystals. ERNEST ALEXANDER AND KARL HERRMANN. *Z. Krist.* 69, 285-99(1928).—Liquid crystals may be of 2 types, smectic and nematic. (Friedel, *C. A.* 17, 3267.) The known facts concerning liquid crystals are in accord with the assumption that the nematic type represents one-dimensional space groups and the smectic type two-dimensional space groups, while regular crystals, of course, are three-dimensional. There is given a list of the 80 space groups in which it is possible to have 2-dimensional development.

L. S. RAMSDELL

The crystal structure of rhenium. V. M. GOLDSCHMIDT. Mineral. Inst. Univ., Oslo. *Naturwissenschaften* 17, 134-5(1929).—Black rhenium powder (10.9 mg. with 0.3% Mo) has hexagonal structure with close packing, $a = 2.752 \pm 0.001$ A. U., $c = 4.448 \pm 0.002$ A. U.; it is similar in this respect to Os. The atom radius of Re is between those of W and Os, 1.371 A. U. By using Noddacks at. wt. of 188.71 ± 0.25 , a value of 21.33 for the d. of the exptl. material is calcd.; for pure Re is calcd. 21.40 ± 0.06 in agreement with measured values.

B. J. C. VAN DER HOEVEN

Hall effect in single metal crystals. P. I. WOLD. *Science* 69, 72(1929); cf. *C. A.* 22, 4339.—The Hall effect in a single crystal of Zn (close-packed hexagonal crystal structure) is 50% larger than in polycryst. Zn.

R. J. HAVIGHURST

Lattice constant of quenched carbon steel. SHINKICHI SEKITO. Tohoku Imp. Univ. *J. Study Metals* 5, 380-4(1928).—The crystal structure of martensite has formerly been supposed to consist solely of the body-centered cubic lattice, but recently Honda and S. proved that this lattice appears only in the interior of quenched steel, while in the portion near surface there appears a body-centered tetragonal lattice of the axial ratio of about 1.07. The present paper reports the exptl. results in which it is shown that the tetragonal structure appearing on the surface diminishes its axial ratio gradually as it goes deeper into the interior to become finally 1 (body-centered cubic lattice). It is further shown that when quenched C steels are annealed, the tetragonal structure gradually changes into the body-centered cubic, without passing through a stage of an intermediate axial ratio. The axial ratio of the tetragonal lattice varies according to the difference of the cooling rate, but generally speaking, the elevation of the quenching temp. and the increase of the C content make the ratio greater.

K. SOMEYA

The growth of solution bodies and spheres of rock salt. WALTER SCHNORR. *Z. Krist.* 68, 1-14(1928).—The final form resulting from crystal growth is independent of the original form. Spheres of NaCl, whether regular or irregular, whether cut or obtained by soln., all went through the same stages of growth and (100) was the final form. The occurrence in nature of the forms (100) + (111) + (210) is due to temporary or partial soln. and later renewed growth, which does not reach the final stage. In solns. contg. high concns. of MgCl₂, the development of (110) is strongly favored as opposed to (210) because of the change of the relative growth velocities.

L. S. RAMSDELL

The pressure transitions of the rubidium halides. LINUS PAULING. *Z. Krist.* 69, 35-40(1928). (In English.)—The vol. contractions accompanying the pressure transitions of RbCl, RbBr and RbI approx. those corresponding to the transition of CsCl, CsBr and CsI from the NaCl to the CsCl structure, so the latter structure is probably correct for the high-pressure forms of the Rb salts. Calcd. values for the increase in interionic distances accompanying the NaCl-CsCl transition agree with observed values. The CsCl structure is stable for alkali halides with high anion deformability and large radius ratio, found only in CsCl, CsBr and CsI, and approximated in case of RbCl, RbBr and RbI.

L. S. RAMSDELL

The crystal structure of tartaric acid, isohydrobenzoïn and rubidium tartrate. A. REIS AND W. SCHNEDDER. *Z. Krist.* 69, 62-76(1928).—Tartaric acid and isohydro-

benzoin ($C_{11}H_{10}O_2$) both crystallize like cane sugar in space group C_2^2 , with 2 formula wts. in the unit cell. A single formula wt. forms an unsymmetrical group. For tartaric acid, $a = 7.68$, $b = 6.03$, $c = 6.18$ A. U. and $\beta = 100^\circ 17'$; for isohydrobenzoin $a = 12.40$, $b = 7.92$, $c = 5.81$ A. U. and $\beta = 92^\circ 53'$. Rb tartrate crystallizes in space group D_2^4 . Each formula wt. forms a group with the symmetry C_4 , and there are 6 formula wts. in the orthohexagonal cell in which $b = 7.17$ and $c = 13.10$ A. U. L. S. R.

The form and potential energy of the isomorphous crystals, ruby and hematite. J. TOPPING. *Proc. Roy. Soc. (London)* A122, 251-73(1929); cf. *C. A.* 20, 2436.—By postulating crystals in which the ions are point charges between which the ordinary electrostatic and certain intrinsic repulsive forces are assumed to be operative, a good account can be given of the 3 parameters and the rhombohedral angle involved in the structure of the crystals Al_2O_3 and Fe_2O_3 . The problem is to det. positions of the point charges in which the potential energy due to the electrostatic and intrinsic repulsive forces is a min. The method is to assume the value of one of the parameters given by the crystal structure detn. to be correct, and to calc. the potential energy for a series of values of the other 2 parameters, the pair of values giving the lowest potential energy being taken as correct. The law of repulsive force between ions is of the form $\mu/r^{\mu+1}$, where r is the distance between ion centers and μ is a force const. which depends on the particular ions under consideration. Values of the force const. given for these ions by Lennard-Jones and Dent (*C. A.* 20, 319, 3252, 21, 679) must be changed, in order that the theoretical configuration of min. potential energy shall agree with the observed configuration. The hexagonal close-packing of O ions at a distance of 2.7 A. U. apart, which has been considered by Bragg and Brown (*C. A.* 20, 1154) as the principle which det. the structure of these and other crystals, is not theoretically possible, but there is a slight distortion from the close-packed arrangement, the calcd. amt. of distortion being very nearly that given by the exptl. data. R. J. HAYDHURST.

The crystal structure of anhydrous silicotungstic acid and related compounds and their probable molecular formulas. ARTHUR G. SCROGGIE AND GEORGE L. CLARK. Univ. of Illinois. *Proc. Nat. Acad. Sci.* 15, 1-8(1929).—By stepwise addn. of alkali to silicotungstic acid, the following modified acids were obtained: $2H_2O \cdot SiO_3 \cdot 10WO_3 \cdot 5H_2O$; $2H_2O \cdot SiO_3 \cdot 8WO_3 \cdot 4H_2O$; $3H_2O \cdot (SiO_3 \cdot 7WO_3) \cdot 4H_2O$. X ray examn. by the powder crystal method of the acid dried at 100° ($4H_2O \cdot SiO_3 \cdot 12WO_3 \cdot 4H_2O$) shows that it crystallizes as a body-centered cube with 2 mols. in a unit cell of side 12.16 A. U. The unit cell is found to be of the same size for the acids mentioned above contg. 8 and 10 W atoms, as well as for the following: $2H_2O \cdot SiO_3 \cdot 12WO_3$; $2H_2O \cdot SiO_3 \cdot 12WO_3 \cdot 6H_2O$. The anhydrous $SiO_3 \cdot 12WO_3$ has a much less symmetrical structure. From the chem. and x ray evidence, it is concluded that the acid has 2 mols. of water which are acidic in nature, and 6 mols. which are non-acidic or alc. in nature. Consequently the modified formula $2H_2O(6H_2O \cdot SiO_3 \cdot 12WO_3)$ or $H_4[(SiO_3)(W_{12}O_{36})(OH)_6]$ is suggested, along with a new spatial structure. Phosphodecimolybdic acid forms a body-centered cube with 16 of the unit cell 14.31 A. U. R. J. HAYDHURST.

Investigations of the structure of artificial ultramarines. IV. Ultramarines of thallium and similar compounds of the bivalent metals calcium, strontium, barium, zinc, manganese and lead. F. M. JASOON. Univ. Groningen. *Verslag van de Wetenschappen Amsterdam* 37, 937-47; *Proc. Acad. Sci. Amsterdam* 32, 156-66(1929); cf. *C. A.* 22, 1067, 1719.—Tl (univalent) ultramarine (I) was prepd. by heating a Guimet salt (I) $Na_4Al_3Si_3O_{14}S_4$ with 44 g. of $TlNO_3$ and 10 cc. H_2O in a sealed tube for 50 hrs. at 160° . The product, a pinkish purple powder, was washed and the x ray powder spectrogram detd. The same product was obtained when Tl_2SO_4 was used. The lattice constants remain practically identical with those of the Na compd. The ultramarines of Ca, Sr, Ba and Mn were prepd. in a similar manner from the 1 and 5 times the theoretical amt. of Ca, etc., iodides. They were washed free from AlI_3 by KCN. Ca, Sr and Ba gave nearly pure olive-green compds. of the type $M^{++}_2Al_3Si_3O_{14}S_4$. By fusing with $M^{++}I_2$, they were converted into colorless (I), from which nearly free (Ba) from Ag. The similar Zn compd. is nearly colorless, shows a light purple tinge. MnI_2 gave a product poorer in Al, corresponding to $Na_2Mn_2Al_3Si_3O_{14}S_4$ compd. contaminated by a small amt. of Al (I). The x-ray spectrograms show that all the belong to the true type, although their spectrograms differ in the distribution of intensity. The Pb (I) (yellow) prepd. as above, $Pb(NO_3)_2$ being used. Pb-Ag (I) (dark greenish gray) was prepd. by melting the Ag compd. with Hg . Attempts to prep. Hg^{++} and Hg^{+} compds. gave products contaminated with Hg salts, but no HgO was formed. Their structure is not cubic and is distinctly different from that of the other (I). V. The absorption reactions of ultramarines and the structure of

nosean (hauyne) and the ultramarines. F. M. JAEGER AND F. A. VAN MELLE, *Verslag Akad. Wetenschappen Amsterdam* 37, 957-70; *Proc. Acad. Sci. Amsterdam* 32, 167-81 (1929).—The rate of substitution of Ag by Na in ultramarine was studied by heating Ag (I) with NaI. The rate of substitution is greater at the beginning and is greater with greater NaI concns. The rate curves indicate that adsorption of NaI first takes place on the surface of the powd. (I). The rate decreases as more Ag atoms have been substituted. The x-ray spectrograms show a striking similarity between nosean ($\text{Na}_{10}\text{Al}_6\text{Si}_6\text{O}_{28}\text{S}_2$), hauyne and the S and Se (I). G. CALINGAERT

The x-ray investigation of pentaerythritol. H. MARK AND G. V. SUSICH. *Z. Krist.* 69, 105-17 (1928).—The symmetry of pentaerythritol as detd. by Nitta (*C. A.* 20, 2435) and Hendricks and Nehmiz (*C. A.* 22, 2089) is confirmed. The crystals are always intergrowths of several individuals, and there is a possibility that they are not tetragonal. Arguments for both tetragonal and orthorhombic symmetry are given. The final decision must be made on single crystals. L. S. RAMSDALL

Resistance hysteresis phenomena of tin, lead, indium and thallium at the temperature of liquid helium. W. J. DE HAAS AND J. VOOGD. *Proc. Acad. Sci. Amsterdam* 32, 206-13 (1929).—See *C. A.* 22, 4287. E. C. M.

Super-conductivity of gallium. W. J. DE HAAS AND J. VOOGD. *Proc. Acad. Sci. Amsterdam* 32, 214-7 (1929).—See *C. A.* 23, 1322. E. C. M.

Entropy diagram for hydrogen. W. H. KEESOM AND D. J. HOUTHOFF. *Rapports et comm. 5th Cong. intern. du froid*, Apr., 1928; *Comm. Phys. Lab. Univ. Leiden. Suppl. No. 65*, 25-8.—Equations and diagrams are given for the range -173° to 27° , based on exptl. results of Kamerlingh Onnes and others. The derivation of the equations is discussed. C. Z. ROSECRANS

Entropy and Mollier diagrams for helium. W. H. KEESOM AND D. J. HOUTHOFF. *Rapports et comm. 5th Cong. intern. du froid*, Apr., 1928; *Comm. Phys. Lab., Univ. Leiden. Suppl. No. 65*, 31-5.—Equations and diagrams are given for the range -173° to 27° , based on exptl. results of Kamerlingh Onnes and others. The derivation of the equations is discussed. C. Z. ROSECRANS

Entropy and Mollier diagrams for nitrogen. W. H. KEESOM AND D. J. HOUTHOFF. *Bull. mens. inst. intern. froid* [2], No. 2, Jan., 1927; *Comm. Phys. Lab., Univ. Leiden. Suppl. No. 65*, 17-22.—Equations and diagrams are given for the range -210° to 0° , based on exptl. results of Kamerlingh Onnes and others. The derivation of the equations is discussed. C. Z. ROSECRANS

Entropy and Mollier diagrams for methane. W. H. KEESOM AND D. J. HOUTHOFF. *Bull. mens. inst. intern. froid* [2], No. 1, July, 1926; *Comm. Phys. Lab., Univ. Leiden. Suppl. No. 65*, 3-8.—The equations and diagrams are based on the exptl. values of Keyes, Taylor and Smith (*C. A.* 17, 668), and cover the range -173° to 0° . The derivation of the equations is discussed. C. Z. ROSECRANS

Entropy and Mollier diagrams for ethylene. W. H. KEESOM AND D. J. HOUTHOFF. *Bull. mens. inst. intern. froid* [2], No. 1, July, 1926; *Comm. Phys. Lab., Univ. Leiden. Suppl. No. 65*, 11-4.—Equations and diagrams are given for the range -173° to 100° . These are based on exptl. results of Cailletet and Mathias, Cardoso and Arni and Villard. The derivation of the equations is discussed. C. Z. ROSECRANS

Kinetic theory of a gas in the neighborhood of a wall. M. BRILLOUIN. *Compt. rend.* 186, 553-8 (1928); *Science Abstracts* 31A, 479.—The radius of curvature of the wall is supposed great compared with the mean distance and mean free path of the gas mols. A double role is attributed to the wall as proposed by Maxwell in 1868: (1) The wall can reflect each incident mol. according to a rigorously defined law; the probability of speed after reflection is then defined by the incident velocity and the mol. circumstances of the impact. (2) The incident gaseous mol. may be absorbed (as in soln.) in the wall itself, perhaps later to be re-emitted without any relation to the speed or direction of the incident mol. In the immediate neighborhood of the wall the distribution of speeds depends too much on the wall for one to be able to define it by one continuous function. The discontinuity persists, but gets less and less away from the wall, but eventually ends in the law of distribution of Maxwell. Two sorts of mols. are considered: (1) Mols. which come from the gaseous mass without having touched the walls; (2) mols. which emanate directly from the wall. Six equations are evolved from which the author deduces the distributions and ds. in the layer of gas near the wall. H. L. D.

Deviations from Dalton's partial-pressure law and their chemical explanation. MAX TRAUTE AND MARTIN GÖRSCHMIDT. *Univ. Heidelberg. Z. anorg. allgem. Chem.* 179, 1-26 (1929).—Ewert (*Dis. Heidelberg* 1925) detd. pressure changes occurring on mixing pairs of inorg. gases, finding that these effects could be calcd. with a precision of about 0.1 mm. Hg from equations of van der Waals, van Laar and Berthelot. T. and

G. measured other pairs of gases, using Emert's app. and method (cf. T. and Emert, *C. A.* 20, 1737). Equal vols. of the components were mixed in const. total vol., and the pressure change was measured by a differential method with a precision of 0.0025 to 0.01 mm. Hg at room temp. Results are tabulated for mixts. of C_2H_4 and H_2 and of Me_2O with CO_2 , SO_2 or $MeCl$ at initial pressure between 700 and 760 mm. and temp. between 0° and 40° . The results are verified by calcs. according to Emert's methods from van Laar's consts. It is found that they agree well for C_2H_4 and H_2 mixts., Δp being of the order $+1.1$ mm.; for mixts. contg. Me_2O the calcd. values are of the order $+0.02$ (SO_2), measured from -17.5 to -10.3 and of the order $+1.0$ (CO_2), measured from -0.22 to $+0.05$. From the 16 pairs of gases so far detd. only those with Me_2O show deviations from the theory of more than 0.1 mm. Hg; the explanation for the behavior of Me_2O is sought in the formation of addn. compds. of the type $Me_2O.R$. It is therefore, assumed that a relation of the type $a_{12} = F \sqrt{a_1 a_2}$ (modified Berthelot) between the van der Waals consts. of compd. and components may hold with $F = \frac{1}{2} \sqrt{K'}$ and $K' = e^{W/T + \beta T}$ approx., in which K' is the equil. const. of the addn. reaction, W and β consts. From 2 Δp values at different temps. W and β can be calcd.; this was done for the 4 mixts. used. The values for Δp interpolated are in good agreement with the measured ones. Approx. values derived for the heat effects during the addn. are 2628 cal. for $Me_2O + SO_2$, 1783 cal. for $Me_2O + CO_2$, 500 cal. for $C_2H_4 + H_2$. It is evident that for the last reaction no real hydrogenation (21,000 cal. heat effect) takes place. By means of addnl. assumptions, the av. durations of the collisions leading to the dimerization are calcd.; they are of the order 10^{-11} to 10^{-12} sec.

B. J. C. VAN DER HOEVEN.

Studies on the permeability of metals to gases. VICTOR LOMBARD. *J. chim. phys.* 25, 587-604(1928). Expts. were made on Ni, Fe and Pt. N_2 , A, H_2 and He were used with Ni; and H_2 with Fe and Pt. Two films of Ni of 0.16 and 0.25 mm. were used with the N_2 and of 0.16 and 0.31 mm. for the other gases. It was found that N_2 penetrates Ni about 100 times as readily as H_2 under similar conditions. N_2 and A penetrate about equally readily while He penetrates Ni much more readily than either N_2 or A. The rate of flow of H_2 through Fe is a log. function of temp., confirming the expts. of Ryder; at a given temp. it is a linear function of the square root of the pressure but for H_2 on Ni; and O_2 on Ag the curve does not pass through the origin. The log. function with temp. holds for the system Pt - H_2 . There is evidence that the inverse law of thickness of film holds for this system.

RAYMOND H. LAMBERT.

The determination of the humidity of a gas with a high dew point. ROGER MARTIN. *Chaleur et ind.* 9, 200-4(1928). Analytical and mostly theoretical. There is given a table of temp., pressure and weight per cu. m. of water, of air measured dry and satd. at 0° and 760 mm. Hg, and the weight of water in g. in air satd. at t° . II. *Ibid.* 253-8. A theoretical discussion with some graphical solutions of aspects of this problem embracing (a) satn. curves, (b) relation between the calories contained in air, its entropy, its temp. and pressure in a mixt. of air and water vapor, (c) weight of water contained, as a function of the temp. of the air and the partial pressure of water, (d) method of using the consts. given in the paper for the detn. of moisture in a gas by means of the wet and dry-bulb thermometers.

S. L. B. ETHERTON.

Entropy and heat of vaporization. W. HERZ. *Z. anorg. allgem. Chem.* 179, 24-8 (1929).—The entropies at 25° and the heats of vaporization per g. at the normal b. ps. of metallic elements and of some halides are tabulated. For any group in the periodic table, the entropy rises and the heat falls with increasing period. The product $S^3 \Delta H$ is found to be approx. const. for each group.

JOSEPH FLEISCHER.

Terpenes and terpene alcohols. I. Vapor pressure-temperature relationship. C. A. PICKETT AND J. M. PETERSON. *Ind. Eng. Chem.* 21, 325-6(1929).—Vapor pressures of α -pinene, β -pinene, dipentene, terpinolene, fenchyl alc. and α -terpineol have been detd. by a modified Ramsey and Young method. B. ps. of the compds. are given.

O. A. NELSON.

The relations between the physical constants of a liquid. V. PRINSKE. *J. Russ. Phys.-Chem. Soc.* 60, 1019-35(1928); *Z. Elektrochem.* 35, 13-7(1929).—Every phys. const. of a liquid changes with temp. according to the equation $\log X = a + b \log T$, where T = crit. temp., X is the phys. const., and a and b are special consts. for the liquid. P. has applied this equation to d., surface tension, viscosity and heat of evapn. In the case of the sp. heat, κ and velocity of sound. From his equation, various elastic relationships between 2 or more phys. consts. of a liquid may be deduced.

S. L. B. E.

The relation between specific rotation and refractive index of a solution. V. *Z. Elektrochem.* 35, 17-8(1929); cf. preceding abstr.—P. applies his general

equation and now writes it $\log \alpha = a + b \log n$, where a and b are coeffs., independent of the concn., α is the sp. rotation and n the refractive index of a soln. S. L. B. E.

A viscosity formula for binary mixtures, the association degree of constituents being taken into consideration. I. TETSUYA ISHIKAWA. Inst. Phys. and Chem. Research, Tokyo. *Bull. Chem. Soc. Japan* 4, 5-15(1929).—The 2 following assumptions are made. "An assoc. mol. is a fast combined mol., a single mol. in which is quite different in any property from a singly existing mol. and is regarded to be a constituent as if it were of a chem. compd. mol." "An assoc. mol. is a group of single mols. which have the self-same dimension with singly existing mols., and the difference between them is no other than the abrupt greatness of the cohesion force of the former in comparison with that of the latter." Using this as his base, T. gives a formula by which the viscosity of a binary mixt. can be calcd. from the consts. of its constituents:

$$\eta = \eta_1 + (\eta_2 - \eta_1) \frac{k_2 a_2 z_m}{k_1 a_1 (1 - z_m) + k_2 a_2 z_m},$$

where a = the association degree, z_m = molar fraction, and k = field const. Using data from the literature, he shows that the calcd. and exptl. values check satisfactorily.

ALBERT L. HENNE

Super-cooled water. LEONARD HAWKES. *Nature* 123, 244(1929).—There appears to be a great change in the properties of supercooled H_2O between -9° and -12° . At -9° , H_2O is quite fluid, while at -12° water "froze," showing no signs of cryst. structure.

FRANK V. JOHNSON, JR.

Electric resistance of powdered bismuth in a magnetic field under various pressures. ALBR. ALTMANN. *Sitzb. Naturforsch.-Ges. Univ. Tartu*. 35, 8-20(1928).—The resistance increases in proportion of the 1.7 power of the field intensity; with increasing pressure the resistance diminishes following a hyperbolic law. Heavy-walled tubes cause a low increase of resistance; the action of the field on coarse powder is smaller than on line.

R. D. BUMBACHER

The influence of cold working on the chemical properties particularly of metals. G. TAMMANN. Univ. of Gottingen. *Z. Elektrochem.* 35, 21-8(1929); cf. *C. A.* 22, 2131.—A metal is less noble in the hard than in the soft condition as can be shown by e. m. f. measurements. Cold working diminishes the extent of the influence of nobler components. Since a hard metal is less noble than a soft metal, the former will ppt. nobler metals faster and this is shown in the use of Fe, Ni, Co, Ag, Au, Pt, Pd. Hg wets hard Ag and mixed crystals of Ag with Au, Sn and Cd easier than soft Ag. Fe, low in C, after much cold working, which thus makes it hard, has a greater soln. velocity in acid than soft iron. Hardened Pd foil absorbs gases much faster than soft Pd, this being also true for other metals. Reduction in size, which also hardens the substance, increases the soln. velocity. Cold working AgBr renders it more susceptible to reduction and an analogous phenomenon is the action of α - and γ -rays on NaCl. The NaCl becomes yellow and the color does not change in sunlight. Cold-working also produces color changes in Au, Ag and Cu alloys.

S. L. B. ETHERTON

Densities of single crystals of iron, nickel and aluminum. SEIJI KAYA. Tohoku Imp. Univ. *J. Study Metals* 5, 385-6(1928).—The d. of single crystals of Fe, Ni and Al were measured and compared with those of polycrystals. It was found that the d. of the single crystal is greater than that of polycrystal by 0.037% in Fe, 0.110% in Ni and by 0.034% in Al.

K. SOMEYA

The cause of thermo-tribo-electric abnormality of glass. M. C. MONTU. *Nuovo cimento* [N. S.] 5, 347-51(1928); cf. *C. A.* 22, 4043.—Expts. made in which strain in glass could be induced by mech. pressure show that mech. tension of the surface is not the preponderant cause of the phenomenon of thermo-tribo-elec. abnormality of glass.

L. T. FAIRHALL

Influence of heating the mercury in the phenomenon of tribo-electricity with glass. VIRGILIO POLARA. *Nuovo cimento* [N. S.] 5, 352-60(1928).—P.'s observations indicate that Hg aged from 8 to 24 hrs. and heated to $40-50^\circ$ is positively excited with respect to glass and, while slow cooling conserves the pos. charge for a period of time varying from 15 to 50 mins., rapid cooling causes the charge to become neg. at once. This is important in the interpretation of the phenomenon of tribo-electricity in that sudden variation in surface tension is not accompanied by aging.

L. T. FAIRHALL

Some adsorption isotherms on a plane platinum surface. WM. G. PALMER. St. John's Coll., Cambridge, Eng. *Proc. Roy. Soc. (London)* A122, 487-96(1929); cf. *C. A.* 19, 595; 20, 2437; 21, 2828.—The advantages of the elec. coherer in adsorption measurements are (1) adsorption takes place on a non-porous and chem. homogeneous surface; (2) a direct test for the bareness of a surface can be applied; (3) only surface films

play a part in the measurement. The disadvantage is that the amt. adsorbed is measured by the crit. cohering voltage rather than by direct measurement. With the coherer, the adsorption isotherms on Pt at 20° of C_6H_6 , EtOH and AcOH in gasoline (b. p. 40-44° and d. 0.640), were detd. The data obtained fit Langmuir's adsorption equation, $a = a_{\infty} \rho c / (1 + \rho c)$ in which ρ represents the "average life." The results are as follows at 20°: C_6H_6 0.18, C_6H_5OH 0.09 and CH_3COOH 0.15. These values compare favorably with Langmuir's for CH_4 , N_2 and O_2 at -183°. C_6H_6 will not sat. a Pt surface. Pt adsorbs only polar mols. to a great extent. ARTHUR FLEISCHER

Adsorption at a water interface. I. B. W. CURRIE AND T. ALTY. U. of Saskatchewan, Canada. *Proc. Roy. Soc. (London)* A122, 622-33(1929); cf. *C. A.* 19, 198; 20, 2005.—A bubble of air immersed in water acquires a neg. charge because of the adsorption of neg. ions at the interface. The measurements of the charge were carried out as in the previous work. It was found, as previously reported, that the charge decreased with the size of the bubble, the rate of decrease increasing with increasing rate of absorption of the bubble by the liquid. In an air-satd. liquid the equil. potential is not reached for 2000 secs. This accounts for the low values at high rates of absorption. A charge on a large bubble is independent of the diam. if measurements are made at equil. The long period for equil. to be reached in dil. NaCl solns. indicates very feeble binding forces between adsorbed ions and the surface. As the size of a bubble is decreased a point is reached where the charge decreases with the decrease in radius. In Type I the drop in charge takes place at first in steps and later continuously. In Type II there is a gradual decrease in charge; dil. NaCl solns. are of this type. In pure water having a cond. of 0.7×10^{-8} mhos there is a const. charge on a bubble down to a radius of 0.033 cm. of 5.4×10^{-4} e.s.u. Red, blue and ultra-violet light have no effect on the charge. Equil. is reached in less than 200 secs. in pure water. ARTHUR FLEISCHER

The equilibrium of heterogeneous systems including electrolytes. III. The effect of an electric field on the adsorption of organic molecules, and the interpretation of electrocapillary curves. J. A. V. BUTLER. Univ. of Edinburgh. *Proc. Roy. Soc. (London)* A122, 399-416(1929); cf. *C. A.* 21, 1048.—By using the electrostatic theory developed in the previous paper equations are derived for the effect of an elec. field on the adsorption of mols. at a Hg-water soln. interface. The max. in electrocapillary curves is shifted by many substances; the shift is ascribed to the orientation of dipoles. The equation deduced satisfactorily reproduces Gouy's data (cf. *Ann. chim. phys.* 20, 145(1903); 8, 291(1906); 9, 75(1906); *C. A.* 10, 3017, 11, 2291). The left-hand side of the curves deviate from the theoretical more than the right. Aliphatic acids, aldehydes, ketones, amides, nitriles and carbohydrates shift the max. to the right. Phenol and other aromatic hydroxy compds. shift it slightly to the left. Substituted NH_4 salts such as tetraethyl NH_4 sulfate shift the max. to the extreme right or to the neg. end of the curve. Pyridine gives a normal curve. On the basis of the dipole moments of disubstituted benzenes the dihydroxy derivs. are assumed to be oriented at the surface with the hydroxy groups in the same direction. No substance more polarizable than water has yet been studied. HCN proved to be inactive. A. L.

The adsorption of carbon dioxide and ammonia on silica gel. A. MAGNUS AND R. KISTNER. *Z. anorg. allgem. Chem.* 179, 215-32(1929).—Adsorption isotherms of CO_2 on silica gel were detd. at -21.2°, -11°, 0°, 25°, 50° and 100° over a pressure range extending from 0.1 to 760 mm. Hg. The heat of adsorption was calcd. from the linear portion of the isotherms by the use of the Clausius-Clapeyron equation, and was found to vary linearly with the temp. Data at higher pressures were used to calculate the repulsion const. in Magnus' equation, which was found to be const. for each isotherm. The H_2O content of the gel was found to have no significant effect on the course of the isotherms. The study of $TiCl_3$, $ZrCl_3$, CaF_2 , BaF_2 , $BaSO_4$ and $NiBr_2$ as adsorbents for CO_2 was attempted, but difficulties were encountered in drying and outgassing. Adsorption isotherms were detd. for NH_3 on silica gels of different H_2O content. The heat of adsorption on practically water-free gel was calcd. from the isotherms and checked calorimetrically. JOSEPH FLEISCHER

Studies of gas-solid equilibria. II. Pressure-concentration equilibria between benzene and (a) ferric oxide gel and (b) silica gel, directly determined under isothermal conditions. BERTRAM LAMBERT AND ARTHUR M. CLARK. Oxford Univ. *Proc. Roy. Soc. (London)* A122, 497-512(1929); cf. *C. A.* 22, 709.—The same samples as previously used were employed in this work. A sealed app. was used having (1) known wt. of gel at const. temp. and with accurate Hg manometer, (2) known wt. of C_6H_6 in an evacuated and calibrated reservoir, (3) means of transferring C_6H_6 from (2) to (1) and vice versa. For Fe_2O_3 isotherms were detd. at 40°, 50° and 60°. The points on the curves were obtained at increasing and decreasing pressures. Where the ascending and descending

isotherms coincided, equil. was reached in $\frac{1}{2}$ hr. In the hysteresis region 2 hrs. was required. The isothermals from pressure-temp. measurements in Part I correspond to the ascending isothermals. For SiO_2 gel, the isotherms were detd. at 15, 25, 40, 50, and 70° . The curves were reversible over the entire temp. range. There is a fundamental difference in the adsorption by Fe_2O_3 and by SiO_2 gel.

The lowering of the vapor pressure of liquid argon by active materials. ARTHUR FLEISCHER, F. HÜTTIG AND ROBERT JUZA. *Z. anorg. allgem. Chem.* 177, 313-22(1928).—The object of the investigation was to det. the capacity of A for entering into chem. combination, and to study the activity of different materials. The active materials were: active C, $\text{Sb}(\text{OH})_3$, active SiO_2 , stannic acid, colloidal NiS , active Ca and Sb_2O_3 . The expts. were made at approx. 84° abs. as follows: liquid A was allowed to condense on the surface or in the pores of the active materials and the change in vapor pressure noted. The wts. of both the active materials and the A were detd. Tables are given showing lowering of vapor pressure with increasing wts. of A condensed. Values of Q and p are calcd. from the equation:

$$\log p = (Q/4.571) + 1.75 \log T - (0.030795 T/4.571) + 1.07.$$

Active C and the oxides had the greatest influence. SiO_2 appears to form a stable compd. in stoichiometric proportions with A. The diameters of the capillaries in the active substances are computed.

O. A. NELSON

Adsorption. MARIE-THERESE ISSELSTEIN. *Phys. Inst. Munster, Westphalia. Physik. Z.* 29, 873-8(1928).—The adsorption of CS_2 , C_3H_8 , and CH_2Cl_2 by powdered glass was measured at 20° and at pressures between 54 and 276 mm. The extent of glass surface was estd. by Schelte's method (cf. *C. A.* 19, 1800). The adsorbed vapors correspond to layers as great as 35 mol. deep. The depth decreases with decreasing pressure.

R. L. DODGE

Absorption phenomena. J. RATELADE AND M. CHETVERGOV. *Rev. gén. mat. col.* 32, 302-5(1928).—The absorption of dyes from mixed solvents by filter-paper and by artificial silk has been investigated with reference to the percentage compn. of the solvent. With "direct diamine" dyes on filter-paper, minima were found with water-MeOH, water-EtOH, and water-pyridine mixts., but not with EtOH-MeOH or EtOH-pyridine mixts. In diphenylmethane and triphenylmethane dyes no minima were found. Similar results were obtained with viscose. The extn. of direct colors from filter-paper by water-alc. and water-pyridine mixts. also showed a min. (cf. Shilov and Pevsner, *C. A.* 20, 1009).

B. C. A.

Preparation of negatively charged sols by means of tartaric acid. V. Physico-chemical properties of tungstate-tartaric acid colloids. A. V. DUMANSKII AND S. I. D'YACHKOVSKII. *J. Russ. Phys. Chem. Soc.* 60, 1053-68(1928).—The addn. of Na tungstate to *d*-tartaric acid solns. gives rise to the formation of a series of colloidal double salts, which undergo hydrolysis on diln.; the degree of dispersion increases with the W content. These colloidal solns. exhibit mutarotation; on concn. they yield vitreous gels, which become blue on exposure to light.

• B. C. A.

Preparation of negatively charged sols by means of tartaric acid. IV. Formation of lead hydroxide sols and gels from alkali tartrates. A. V. DUMANSKII AND A. P. BUNTIN. *J. Russ. Phys.-Chem. Soc.* 60, 933-49(1928); cf. *C. A.* 23, 1333.—Solns. prepd. by dissolving PbSO_4 and $\text{Pb}(\text{OH})_2$ in alkali tartrate solns. in presence of excess of alkali or Pb tartrate in alkalies contain the complex $\text{C}_4\text{H}_4\text{O}_6\text{R}_2\text{Pb}$, where R is K, Na, or NH_4 . When the alky. of the soln. is small, colloidal solns. of $\text{Pb}(\text{OH})_2$ may form, passing into vitreous, transparent gels if the soln. contains more than 3% Pb. Lead alkali tartrates may be isolated by adding alk. alkali to solns. of Pb tartrate. Solns. of this salt are alk. and levorotatory, and on diln. their cond. changes considerably, indicating a high degree of hydrolysis. On dialysis, colloidal solns. of $\text{Pb}(\text{OH})_2$ are obtained. These sols are made up of negatively charged particles, readily coagulable by electrolytes and of the compn. expressed by $\text{Na}_2[\text{C}_4\text{H}_4\text{O}_6\text{Pb}.n\text{Pb}(\text{OH})_2]$.

B. C. A.

Chemical factors which determine the stability of colloids. LUIGI SABBATINI. *Atti. Ist. Veneto* 87, Part II, 321-4(1927-8).—The action of CHCl_3 on more than 30 org. and inorg. colloids was investigated. Invariably electronegative colloids were stabilized, but electropositive colloids were not.

S. L. B. ETHERTON

The kinetics of the coagulation of gold sols. ANN E. DAVIES. Univ. of Liverpool. *J. Phys. Chem.* 33, 274-84(1929).—D. finds that the rate of coagulation by electrolytes of Au sols maintained at 80° changes with time. The term "thermo-senescence" or "thermo-aging" has been coined to define the phenomenon. Thermo-senescence is very pronounced at 80° and consists of (a) a primary effect, which is a fall in the Smolouchowski coeff. β with increase of the aging period of the sol, until β reaches a min. after

various nitrates dissolved as follows: KNO_3 30.34 g., $\text{Sr}(\text{NO}_3)_2$ 8.4 g., $\text{Al}(\text{NO}_3)_3$ 10.6 g.; KNO_3 dissolved just as much as in pure water and in the satd. soln. of these 2 salts 16.8 g. of $\text{Sr}(\text{NO}_3)_2$ dissolved. In the satd. soln. of NaNO_3 with the 8.4 g. of $\text{Sr}(\text{NO}_3)_2$ dissolved, one may dissolve 30.34 g. of KNO_3 and in this soln. 8.4 g. more of $\text{Sr}(\text{NO}_3)_2$ could be dissolved. $\text{Ba}(\text{NO}_3)_2$ did not dissolve in the NaNO_3 soln. and did not ppt. it. In a satd. soln. of KNO_3 the various nitrates dissolved as follows: NaNO_3 9.6 g., $\text{Sr}(\text{NO}_3)_2$ 66.26 g., $\text{Ba}(\text{NO}_3)_2$ 1.6 g., and $\text{Al}(\text{NO}_3)_3$ 1.6 g. The soly. of $\text{Sr}(\text{NO}_3)_2$ is as great as in pure water. In this satd. soln. 44.8 g. of NaNO_3 dissolved. In a satd.

soln. of K_2SO_4 9 g. of anhyd. Na_2SO_4 dissolved, none of anhyd. ZnSO_4 . In a satd. soln. of Na_2CO_3 83 g. of K_2CO_3 dissolved, while in pure water 108 g. of K_2CO_3 dissolved. Five expts. were conducted in satd. solns. with a common cation, but a different anion. (1) In a satd. soln. of NaCl 2.2 g. of NaNO_3 dissolved. Only 1.6 g. NaCl dissolved in a satd. soln. of NaNO_3 . (2) In a satd. soln. of KCl 12.2 g. of KNO_3 dissolved, but no KCl dissolved in a satd. soln. of KNO_3 . The smallest quantity of KCl pptd. KNO_3 and the more KCl added the more KNO_3 came out of soln. and KCl went into soln. (3) In a satd. soln. of BaCl_2 8.74 g. of $\text{Ba}(\text{NO}_3)_2$ dissolved but in a satd. soln. of $\text{Ba}(\text{NO}_3)_2$ 37.24 g. of BaCl_2 dissolved. (4) In a satd. soln. of SrCl_2 37.6 g. of $\text{Sr}(\text{NO}_3)_2$ dissolved and in a satd. soln. of $\text{Sr}(\text{NO}_3)_2$ only 9 g. of SrCl_2 dissolved. (5) In a satd. soln. of NH_4Cl neither $(\text{NH}_4)_2\text{SO}_4$ nor $(\text{NH}_4)_2\text{C}_2\text{O}_4$ dissolved. The addn. of 0.1 g. of either of these pptd. NH_4Cl . In the second series of expts. tests were made with satd. solns., without common ions. In 100 cc. of a satd. soln. of NH_4Cl the following dissolved: NaNO_3 48.4 g., KNO_3 30.34 g., $\text{Ba}(\text{NO}_3)_2$ 1.20 g., $\text{Al}(\text{NO}_3)_3$ 44.6 g., Na_2SO_4 3.4 g. In the satd. soln. of NH_4Cl and NaNO_3 20.8 g. of KNO_3 could be dissolved. The temp. of the soln. drops when the NaNO_3 is added to the NH_4Cl ; it drops still further when the KNO_3 is added to the soln. of the 2 salts. The KNO_3 in NH_4Cl soln. dissolves as much as in pure water. An excess of the other salts mentioned causes a pptn. of the NH_4Cl . In a satd. soln. of $(\text{NH}_4)_2\text{SO}_4$ only 6.4 g. NaNO_3 and 0.4 g. NaCl could be dissolved. $\text{Ba}(\text{NO}_3)_2$, $\text{Al}(\text{NO}_3)_3$, KCl and BaCl_2 did not dissolve at all. In a satd. soln. of KCl 14.8 g. of NaNO_3 , 44.2 g. of $\text{Sr}(\text{NO}_3)_2$ and 8.74 g. of $\text{Ba}(\text{NO}_3)_2$ dissolved. In a satd. soln. of NaCl 30.34 g. of KNO_3 and 3.20 g. of $\text{Ba}(\text{NO}_3)_2$ dissolved. In a satd. soln. of BaCl_2 3.6 g. of NaNO_3 , 6.4 g. of KNO_3 and 2.4 g. of $\text{Sr}(\text{NO}_3)_2$ dissolved. In a satd. soln. of SrCl_2 19.2 g. of NaNO_3 and 30.4 g. of KNO_3 dissolved. In a satd. soln. of KNO_3 the various salts dissolved as follows: NaCl 30.4 g., SrCl_2 51.09 g., BaCl_2 5.6 g., HgCl_2 5.0 g. In a satd. soln. of $\text{Ba}(\text{NO}_3)_2$ the various salts dissolved as follows: NaCl 30.4 g., KCl 32.5 g., SrCl_2 4.4 g., NH_4Cl 36.4 g. In a satd. soln. of $\text{Sr}(\text{NO}_3)_2$ the salts dissolved as follows: NaCl 15.6 g., KCl 16.8 g., NH_4Cl 29.8 g. In a satd. soln. of NaNO_3 the salts dissolved as follows: KCl 5 g., NH_4Cl 12.3 g., $\text{Sr}(\text{NO}_3)_2$ 6.8 g.; BaCl_2 and HgCl_2 did not dissolve. In a satd. soln. of HgCl_2 the salts dissolved as follows: NaNO_3 83.97 g., KNO_3 30.34 g., $\text{Ba}(\text{NO}_3)_2$ 8.74 g., and NH_4Cl 36.4 g. In a table a list is given of 19 salts which dissolve in a satd. soln. of other salts in the same quantities as in pure water. A German summary of a theoretical discussion of the results is appended.

J. S. JOFFE

The system *o*-cresol-methanol-water. GAZA VON SZELÉNYI. Hochschule Budapest. *Z. Elektrochem.* 35, 33-7(1929).—The simultaneous soly. of the system is worked out for 10 different contents of MeOH from 0 to 44% and the crit. soln. temp. detd. The concn. of MeOH was detd. by the pycnometer. Only upper, max., and critical soln. temps. exist. The critical soln. temp. of the *o*-cresol-water mixt. was proved to be 169.7° with 39.5 weight % of *o*-cresol and 60.5 weight % of water. S. L. B. ETHERTON

A new method for measuring osmotic pressure. R. V. TOWNEND. *J. Am. Chem. Soc.* 50, 2958-6(1928).—Correction: The first sentence in the abstract *C. A.* 23, 752 should read: "The method is applicable to dil. solns. of any non-volatile solute in a volatile solvent."

DON BROUSSÉ

Ebullioscopic determination of complexes formed by mercuric chloride and alkali chlorides. Association of mercuric chloride. F. BOURION AND E. ROUYER. *Ann. chim.* 10, 263-355(1928); cf. *C. A.* 23, 557.—The assocn. of HgCl_2 in aq. soln. has been studied by the ebullioscopic method. The concns. ranged from 0.175 to 1.75 mol./l. At 25° and 40° (concn. 0.37) there is an equil. between simple and double mols., while at 100° (concn. 0.5 to 1.75) the equil. involves only simple and triple mols. Nevertheless, there is a possibility that double mols. exist at 100° when the concn. is smaller than 0.2. At 15° , the d. of a satd. aq. HgCl_2 soln. is 5. In the application of the ebullioscopic method to the detn. of complexes formed with alkali chlorides, it is necessary to consider the concns. of both the single and assocd. mols. of HgCl_2 . The max. devia-

tion of the rise in b. p. for corresponding solns. contg. HgCl_2 and KCl , NH_4Cl or NaCl from the additive value for the sep. salt solns. corresponds with 0.4 HgCl_2 and 0.6 alkali chloride. This suggests a mixt. of the complexes M_2HgCl_4 and MHgCl_3 , a view which is confirmed by other evidence. The values of $k = C_{\text{HCO}_2\text{Na}} \times C_{\text{HgCl}_2} / C_{\text{M}_2\text{HgCl}_4}$ are 0.0545 for KCl and 0.131 for NaCl , when the concns. are calcd. at 15° . A study of the reduction of HgCl_2 with Na formate shows that in the presence of a large excess of formate, the velocity coeff. corresponds to a bimol. reaction and is const. A similar result is obtained with NaOAc . Since these are stoichiometrically trimol. reactions, an explanation is suggested in terms of the complexes formed by HgCl_2 and NaOAc at 100° . The reduction is formulated: $[4\text{HgCl}_2 \cdot 5\text{AcONa}] + \text{HCO}_2\text{Na} = 2\text{HgCl}_2 + \text{HCl} + \text{NaCl} + \text{CO}_2 + 5\text{AcONa} + 2\text{HgCl}_2$. A const. bimol. reaction coeff. is obtained with a sufficient excess of formate or acetate, but otherwise the NaCl formed produces a stable, difficultly reducible complex with HgCl_2 , thus causing the coeff. to decrease as the reaction proceeds. $\text{Hg}(\text{CN})_2$ raises the b. p. normally at all concns. up to 1.75 mols/l. The absence of hydrolysis is due to the low value of the ionization coeff. (10^{-13}). The formation of complexes between $\text{Hg}(\text{CN})_2$ and alkali or earth-alk. halides has been investigated by methods analogous to those reported for HgCl_2 . The complexes with KCl , NaCl , NH_4Cl and KI are of the type $\text{M}'[\text{Hg}(\text{CN})_2]$; with MgCl_2 , CaCl_2 and SrCl_2 , they are of the type $\text{M}''[\text{Hg}(\text{CN})_2 \cdot \text{X}_2]$. All the complexes, except the 2 last ones, have been actually isolated. There was no evidence of complexes contg. a double mol. $\text{Hg}_2(\text{CN})_4$. With BaCl_2 , the complex $\text{Ba}[\text{Hg}_2(\text{CN})_4 \cdot \text{Cl}_2]$ was formed. The value of $k = C_{\text{Hg}(\text{CN})_2} \times C_{\text{MX}} / C_{\text{M}[\text{Hg}(\text{CN})_2]}$ is 1.3 for KCl and 0.87 for KBr , calcd. at 15° . The d. of a satd. aq. soln. of $\text{Hg}(\text{CN})_2$ is 4 at 15° .

Estimation of p_H in salt solutions. ALFRED NEUMANN. *Pharm. Ztg* 74, 2, 8-10 (1929).
W. O. E.

Electrolytic solution force and electrolytic ion state. IV. Solution and solvation energies, their calculation and comparison. Are the electrolytic ions solvated ions? KARL FRIEDENHAGEN. *Chem. Inst Greifswald. Z. physik. Chem., Abt. A*, 140, 15-17 (1929); cf. *C. A.* 22, 2700. For a series of elements, F. defines and calculates: (a) the electrolytic soln. energy, which represents the transformation of a gas atom into a soln. ion, (b) the solvation energy, which represents the transformation of a gas ion into a soln. ion. In general, (b) is larger than (a). The soln. energy covers all the interactions between the solvent and the solute. There is actually no good reason to believe that soln. ions are solvated gas ions; this assumption would involve many difficulties. The partition coeff. of the ions between the gaseous and the liquid phases is of a different order of magnitude than the ratio of the dielec. consts. of the media. As was already pointed out in the previous papers, there is little possibility of representing the electrolytic dissocn. as a partition of charged ions between 2 media of different dielec. const.
A. L. HENSE

Properties of pure hydrogen peroxide. VI. G. L. MATHEWSON AND G. MAASS. McGill Univ. *J. Am. Chem. Soc.* 51, 674-67 (1929); cf. *C. A.* 19, 759. M_p curves were detd. in pure (98%) H_2O_2 and compared with the analogous curves in H_2O for KCl , K_2SO_4 , NaF and MeOH . Curves were also obtained for Et_2O and H_2SO_4 . H_2O_2 The oils which sep. on mixing anhyd. Et_2O solns. of amines and H_2O_2 were shown to be mol. compds. of the bases and H_2O_2 . The mol. heat of decompn. of pure H_2O_2 into H_2O and O_2 at atm. pressure and 20° was found to be 23,450 cal. A detn. of the vapor d. of H_2O_2 at 90° gave a mol. wt. of 34. At its b. p. (151°) pure H_2O_2 decomposes with a violent explosion, which is deadened by the addn. of a little H_2O or KCl .
J. K.

of hydrolysis of 1,2-oxide compounds in acid solutions. G. SMITH AND W. O. E. Lund Univ. *Swensk Kem. Tids.* 40, 221-6 (1928); cf. Smith and Wade *ibid.* 22, 328. The course of hydrolysis in glycerol glycidate soln. was followed by the change in vol. (cf. Bergsted and Gugenheim, *C. A.* 21, 2803). HClO_4 was used as catalyst, and since it affects the vol. measurements less than other acids. The reaction is bimol. with a deviation in k less than 1%. Rate const./acid concn. is 0.108 for 1:1 HClO_4 and HNO_3 at 25° . This ratio lies between ethylene oxide (0.22) and epichlorohydrin (0.021). Fumarylglucide acids are stronger than the tartaric acids formed on hydrolysis and these reactions were followed by potentiometric measurements. These expts. were made in closed vessels at 97° . Nearly identical titration values before and after the reaction ruled out errors due to formation of CO_2 . In the cat. contg. HClO_4 the rate const. came to 0.0047 for the 1st 15 mins. and increased to 0.0054 after 30 mins. All series showed the same increase. Hydrolysis takes place in the fumaric compds. without mineral acids. The rate increases with diln. and the degree of dissocn. but does not parallel the H^+ -ion concn. as is usual with neutral oxide compds. The mono-basic

ion of the acid hydrolyzes. The *trans*-configuration hydrolyzes slower than the *cis*-.

Monochloramine and hydrazine. II. Formation of hydrazine and decomposition of monochloramine in ammoniacal solution. MAX BODENSTEIN. Univ. Berlin. *Z. phys. Chem.*, Abt. A, 139, 397-415(1928); cf. *C. A.* 23, 754.—Raschig found that glue and similar substances favor the formation of N_2H_4 from NH_2Cl and NH_3 , and attributed the phenomenon to the presence of catalysts in the water of soln. B. finds that a complete purification of H_2O (distn. with a Pt or Sn condenser) does not change the yield. Cu, bivalent Fe and Co ions paralyze the reaction by adsorption of the metallic ions on the glue or mannitol. The N_2H_4 yield increases with the temp. N_2H_4 formation and decompn. are related. N_2H_4 formation is the primary step; if NH_2Cl is rapidly eliminated (high temp. and excess NH_3) it does not react with the N_2H_4 formed; but if the reaction is conducted slowly, N_2H_4 is reacted upon as soon as it is formed by NH_2Cl still present, and decomposes into N_2 and NH_4Cl . To prove the correctness of these views, kinetic measurements of the NH_2Cl decompn. were made. The conditions were so adjusted that no trace of N_2H_4 could be detected: this required a strong excess of NH_3 and a temp. $< 40^\circ$. The reaction was followed by measuring the N evolved and by titration; the results were not absolutely concordant, and the discrepancy is attributed to side-reactions. Nevertheless, it is safe to assume that the reaction is proportional to the NH_2Cl and NH_3 concns., that the temp. coeff. is large, and that Cu ions have only a small catalytic effect. The 2 steps of the reaction are: (I) $NH_2Cl + NH_3 = N_2H_4 + HCl$ and (II) $N_2H_4 + 2NH_2Cl = N_2 + 2NH_4Cl$. I is a relatively slow reaction and can be measured; it has a large temp. coeff. II is very rapid and its temp. coeff. is negligible; it is the only one to be catalyzed by Cu. Cu acts only when the N_2H_4 concn. is high, which was not the case in the present expts. The Raschig equation is the summation of I and II. Joyner made the statement that NH_4 salts decreased the N_2H_4 yield, and assumed that these salts were not acting as such, but brought some unknown catalysts into play; this explanation is not satisfactory.

ALBERT L. HENNE

The oxidation potentials of some hypochlorite solutions. V. H. REMINGTON AND H. M. TRIMBLE. Okla. Agr. and Mech. Coll. *J. Phys. Chem.* 33, 424-34(1929).—A study was made of the potential in hypochlorite solns. between a Pt electrode and a 0.1 N calomel half-cell. Reproducible results were obtained only with new, clean Pt wire which had been glowd electrically to remove gases. Com. hypochlorite preps. were markedly affected by CO_2 . It was found possible, though tedious, to titrate hypochlorite solns. in absence of CO_2 electrometrically, end-points being obtained corresponding to neutralization of $HOCl$ and of HCl . Potentials in solns. made by adding pure hypochlorous acid to Sörenson's phosphate buffer mixts., and to Auerbach and Pick's carbonate-bicarbonate mixts., increased with increasing H-ion concn., but there was an unexplained discontinuity between the 2 series.

T. H. CHILTON

Velocity coefficients of hydrolysis of nitroacetanilide and of the secondary reaction of hydrolysis of *p*-nitroaniline with elimination of ammonia. A. A. KUROCHKIN. *J. Russ. Phys.-Chem. Soc.* 60, 1147-50(1928).—The velocity coeff. for the hydrolysis with 4% NaOH soln. of *p*-nitroacetanilide at 100° is 0.0025, and that of formation of *p*-nitrophenol from *p*-nitroaniline is 0.005.

B. C. A.

Partition of nitric acid between sodium and potassium hydroxide. V. I. NIKOLAEV. *J. Russ. Phys.-Chem. Soc.* 60, 893-904(1928).—A phase diagram for the quaternary system $K_2O-Na_2O-N_2O_5-H_2O$ is described.

B. C. A.

Water-gas equilibrium and flame temperature. YRJÖ KAUKO. *Nord. Kemi-smölet.* (Finland) 1928, 167-8.—Methods of detg. the flame temp. at which the water-gas equil. takes place are discussed. For an alc. flame the temp. is 1300° . O. A. N.

Reciprocal displacement of benzoic and salicylic acids from their combinations with *m*-phenylenediamine. G. K. GLININ. Vsesoyuz Acad. Nauk. *J. Russ. Phys.-Chem. Soc.* 60, 1641-53(1928).—Since Baskov (*C. A.* 9, 2173) has shown that an instantaneous equil. is established in systems of acids and bases, the study of the distribution of an org. base between 2 org. acids was undertaken by using the method of thermic analysis and taking as an object of study *m*-phenylenediamine, which, according to the investigations of Kremann and collaborators (*C. A.* 20, 1224), forms well-defined compds. with acids. The base, together with benzoic and salicylic acids, forms a reciprocal system of chem. interaction: $C_6H_4COOH.m-C_6H_4(NH_2)_2 + C_6H_4(OH)COOH \rightleftharpoons C_6H_4(OH)COOH.m-C_6H_4(NH_2)_2 + C_6H_4COOH$, which gives a diagram perfectly analogous to that of reciprocal systems of double decompn. (Bergman, *C. A.* 21, 523). Since benzoic acid is unable to displace salicylic acid from its combination with the base, the equil. tends toward the irreversible formation of $C_6H_4(OH)COOH.m-$

$C_6H_4(NH_2)_2$. The base is bivalent, but neutral salt is not formed with either of the 2 acids. The fusion curves of the following systems were studied: (1) *Benzoic acid and salicylic acid*: expts. show that this is a simple binary system with 1 eutectic at 108.5° , compn. 60.4 mol. % benzoic acid. (2) *Benzoic acid and m-phenylenediamine*: simple system with a eutectic at 81.5° corresponding to the compn. 64 mol. % benzoic acid. (3) *Salicylic acid and m-phenylenediamine*: simple system with an eutectic at 113° corresponding to the compn. 67.9 mol. % salicylic acid. (4) *Benzoic acid-m-phenylenediamine (1:1) and salicylic acid-m-phenylenediamine (1:1)* (difficulty was experienced with resinification): the lowest fusing temp. is 72° (the compn. being 22.2 mol. % salicylic acid-m-phenylenediamine). (5) *Benzoic acid-m-phenylenediamine and salicylic acid*: there was less resinification than in the preceding case, but obstinate over-cooling; there is a triple eutectic at about 85° for the compn. 65 mol. % benzoic acid, 30 mol. % salicylic acid-m-phenylenediamine and 15 mol. % salicylic acid; another eutectic at 66.5° corresponding to the compn. 22.5 mol. % benzoic acid, 15 mol. % salicylic acid-m-phenylenediamine and 62.5 mol. % benzoic acid-m-phenylenediamine. The curve shows 3 branches intersecting at 2 min. points corresponding to temps. 75.5° and 103.5° , the intersections representing 2 stable ternary systems. (6) *Benzoic acid and salicylic acid-m-phenylenediamine*: This is a simple system with an eutectic at 90° corresponding to 66 mol. % benzoic acid; there is practically no interaction between the 2 components. On the basis of above results, a *squire of interaction of the 4 components* C_6H_5COOH , C_6H_4COOH , $m-C_6H_4(NH_2)_2$, $C_6H_4(OH)COOH$ $m-C_6H_4(NH_2)_2$, and $C_6H_4(OH)COOH$ was constructed in which the fields of the components are shown delimited by lines of reciprocal crystn.; the directions of the lines are toward common centers, namely, triple eutectic points. The drawing discloses 4 fields; the one occupied by salicylic acid-m-phenylenediamine is the largest, which shows the stability of this compd. in the given system. The field corresponding to benzoic acid-m-phenylenediamine is very small.

BERNARD NELSON

The mechanism of the homogenous combination of hydrogen and oxygen. H. W. THOMPSON AND C. N. HINMELWOOD. *Proc. Roy. Soc. (London)* A122, 610-21 (1929). cf. *C. A.* 22, 3816, 4324. For a chain reaction, the equation $v = F(c) / (1 + a + b)$ (1 - a) holds in which v is velocity, $F(c)$ is the concn. of reacting substances to which the no. of chains formed per unit time is proportional, $f(c, r)$ is the concn. or surface of the vessel, governing the rate of breaking of the chains, A is a const. for one kind of mol.; a is the av. no. of mols. activated in each act of transformation. If $a \leq 1$, the expression for v is finite though it may be large. If $a > 1$, $v \rightarrow \infty$. This means that a small change in a may change a finite reaction velocity to ∞ , or that a small change in concn. may result in an abrupt transition from a slow reaction to an explosion. The reaction between H_2 and O_2 in the gas phase at 500-600° is a chain reaction. 1. chains are interrupted principally by deactivation at the walls. N_2O , between upper and lower limit of concn. can initiate instantaneous ignition in mixts. of H_2 and O_2 where the rate is normally negligibly small. If O_2 is allowed to enter a 2-l. cc. quartz bulb at 550° contg. an atm. of H_2 , immediate inflammation occurs at H_2 pressures between 30-40 mm. and 84 mm.; there is no inflammation above 84 mm. and very slow combination below 30-40 mm. If H_2 is added to O_2 the upper limit is 145 mm. To prevent ignition $3 \times$ the deficiency in pressure is added by introducing iron. If H_2 and O_2 are mixed before entering the reaction vessel, ignition occurs as soon as the lower limit is passed. This lower limit is difficult to find because of the weak explosion. The upper crit. pressure decreases with rise in the ratio of H_2 to O_2 . The upper limit is also lowered by A , though not considerably. The crit. pressure was found to be practically independent of the nature and extent of the surface of the reaction vessel. That the upper limit is independent of the surface is striking, since the velocity is greatly diminished above the upper limit by increasing the surface. Above the upper limit, the reaction chains are started by active steam mols. The chains are propagated with stationary velocities. At high pressures, the mechanism may be represented by the equation $2H_2 + O_2 = 2H_2O$. At low pressures the mechanism is: $H_2 + O_2 = H_2O_2$ and $H_2O_2 + H_2 = 2H_2O$. The upper and lower crit. pressures correspond to the N_2O crit. pressures. At the low pres., the stationary character of the reaction is maintained by wall deactivation, while at high pressures and hence high concn. of peroxide the mols. exert a mutually destructive effect and interrupt chains much as antiknock compds. do. The peroxide theory explains (1) crit. limits in pure H_2 and O_2 , (2) influence of N_2O , (3) bimol. process at low pressure and termol. at high pressure. It is more difficult to initiate flame in intensively dried mixts.; the water mols. act as centers of reaction. N_2O is less effective than N_2O_4 in initiating flame, HCl causes an acceleration, while SO_2 has no observable effect.

ARTHUR FLEISCHER

Note on the history of catalysis. EDMUND O. VON LIPPMANN. *Chem.-Zig.* 53, 22 (1929).—The term *catalysis* was used by Libavius in 1597, revived by Berzelius in 1835, and given its modern definition by Ostwald 50 years or more later. Albertus Magnus (1193–1280) and Bartholomaeus Anglicus (1230) refer to the action of demons in hastening changes, as when "sticks are turned into serpents" by magicians. St. Augustine (4th century) and Apulejus (2nd century), basing their statements upon oriental learning, said that the devil himself was responsible for such manifestations. W. C. E.

An extension of the intermediate-compound theory of catalysis in gas reactions. H. H. STORCH. *J. Phys. Chem.* 33, 456–8 (1929).—The theory proposed to account for the rates of unimol. gas reactions may be applied to cases of catalysis, by making the same assumption with regard to an intermediate compd. of the catalyst and reactant as is made with regard to the complex mols. that undergo unimol. decompn., namely, that some of the internal energy of such mols. with several degrees of freedom is available for activation by collision. T. H. CHILTON

Homogeneous catalysis. I. General relations. CH. MOUREU. *Trans. Faraday Soc.* 24, 704 (1928).—A crit. review is presented of a paper previously reported by Dhar (cf. C. A. 23, 1339). P. H. EMMETT

Homogeneous catalysis. I. General relations. A. EGERTON. *Trans. Faraday Soc.* 24, 697–701 (1928).—A discussion of 2 points of interest in combustion and the theory of *antiknock compds.*: (1) the nature of the primary centers which initiate combustion reactions and (2) the circumstances which affect the life of an active mol. P. H. EMMETT

Homogeneous catalysis. I. General relations. W. E. GARNER. *Trans. Faraday Soc.* 24, 701–2 (1928).—G. points out the exemplification of several types of catalytic action in the speeding up by H_2 or H_2O vapor of the gaseous combustion of CO in O_2 . P. H. EMMETT

The catalytic effect of ruthenium salts on the reduction of perchloric acid by hydrobromic acid. WM. R. CROWELL, DON M. YOST AND JAMES M. CARTER. *J. Am. Chem. Soc.* 51, 786–94 (1929).—The influence of Ru salts on the rate of reduction of $HClO_4$ by HBr was investigated. Tervalent Ru had a much greater catalytic effect than quadrivalent Ru. The authors postulate the oxidation of the tervalent Ru to the hexavalent or septivalent form as the step in the reaction detg. its rate. The high-valence form is then reduced almost immediately to the tervalent state. Br inhibits the reaction by slowly oxidizing tervalent Ru to the less active quadrivalent form. P. H. EMMETT

Chemical dynamics of autocatalytic processes. VII. Decomposition velocity of aqueous solution of bromosuccinic acid with liberation of hydrobromic acid. JAN ZAWIDZKI AND WANDA WYCZALKOWSKA. Polytechnikum Warsaw. *Bull. Intern. acad. Polonaise* 1928, 293–60; cf. C. A. 18, 2832.—The velocity with which HBr is liberated by bromosuccinic acid was measured. This process is autocatalytically retarded by the H and Br ions liberated. The decompn. velocity of bromosuccinic acid is represented by $dx/dt = k(a - x) 2x$. At 75° , $k = 0.000154$. The decompn. was also investigated in the presence of an excess of HBr , HCl , HNO_3 , Na_2SO_4 , $NaBr$, KBr and $NaCl$. The value of k was always 0.000154. ALBERT L. HENNE

Homogeneous catalysis. III. Neutral salt and activity effects. M. POLANYI. *Trans. Faraday Soc.* 24, 733–4 (1928).—The coincidence of the reaction velocity of the decompn. of N_2O_5 , as well as the racemization of pinene in the gas phase and in solns., can be explained by a suitable conception of the mechanism of chem. reactions going on in the interior of a mol. R. L. DODGE

Homogeneous catalysis. III. Neutral salt and activity effects. A. LAPWORTH. *Trans. Faraday Soc.* 24, 721–2 (1928).—Polemical. R. L. DODGE

Homogeneous catalysis. III. Neutral salt and activity effects. H. M. DAWSON. *Trans. Faraday Soc.* 24, 723–5 (1928).—Polemical. R. L. DODGE

The thermal decomposition of ammonia on iron catalysts. II. C. H. KUNSMAN. *J. Am. Chem. Soc.* 51, 688–95 (1929).—The rate of decompn. of NH_3 on finely powdered Fe catalysts coated on Pt filaments was detd. by a static method over a temp. range of 475 – 750° and at initial NH_3 pressures of from 2 to 30 cm. The decompn. is strongly inhibited by H_2 . The apparent energy of activation varies from 20,000 to 50,000 cal. per mol. of NH_3 . P. H. EMMETT

The gauze catalyst in ammonia oxidation. G. A. PERLEY AND M. W. VARRELL. Univ. of New Hampshire. *Ind. Eng. Chem.* 21, 222–3 (1929).—Expts. on the oxidation of NH_3 to NO by air at atm. pressure showed that a multi-layer Pt gauze catalyst had a greater capacity and a higher efficiency than a single gauze, irrespective of whether the layers were in direct contact or not. The use of sepd. Pt gauze layers with a pre-

heated gas mixt. gave nearly as high oxidation efficiencies, and no greater capacities than with catalyst layers in close contact. An inlet gas flow (9-10% NH_3 in air) of approx. 1.61 per sq. cm. per min., preheated to 470° gave the highest efficiency. The catalyst contact time was approx. 0.00019 sec.

R. L. DODGE

The phase rule and the boundary law of Euler. OTTO RÜDEL. Rio Grande do Sur. *Z. Elektrochem.* 35, 54(1929).—The phase-rule equation $P + F = C + 2$ is considered mathematically identical with the boundary law of Euler in crystallography, $F + E = C + 2$. The component number C of the phase rule is identical with the boundary number of Euler's rule. Algebraically, P is identical with the surfaces and also the corners of a crystal. Similarly, for the degrees of freedom. From the crystallographers standpoint, the surface corresponds to phases, corners to freedom and boundaries to components.

S. L. B. ETHERTON

Equilibrium diagram of the cobalt-molybdenum system. TAKESHI TAKAKI. Tohoku Imp. Univ. *J. Study of Metals* 5, 364-76(1928).—The equil. diagram was detd. by the dilatometric method, magnetic analysis and microscopic observation. This system has ϵ and η phases besides a γ phase, which is the solid soln. of Mo in Co, and a δ phase, which is the solid soln. of Co in Mo. The η phase, is considered to be a solid soln. between the δ phase and the compd. Co_3Mo , which is formed at 1550° and at 1340° decomposes into $\epsilon + \delta$. The ϵ phase is the solid soln. between the η phase and the compd. CoMo , which is formed at 1500°. This phase forms a eutectic with the γ phase. The γ phase changes into the H phase; the transition point (hexagonal \rightleftharpoons face-centered cubic), which is at 472° in pure Co, rises on heating with the addn. of Mo and lowers on cooling. With the alloy contg. 13-16% Co the transformation point is below room temp. Above 17% Mo, the transformation occurs at high temp. even on cooling, while with the alloy contg. more than 22% Mo the transformation points on cooling and on heating are identical. When the Mo content is 27 to 55%, the alloy undergoes the reaction $\gamma + \epsilon \rightleftharpoons \text{H}$ at 1040°. The alloys between 58 and 71% and those between 62 and 96% Mo contain two solid solns. ϵ and η as the result of the reaction $\text{L} + \eta \rightleftharpoons \epsilon$ at about 1500°, and $\text{L} + \delta \rightleftharpoons \eta$ at 1550°, resp.; the two solid solns. are mainly composed of CoMo and Co_3Mo . The ϵ phase produces a eutectic with the γ solid soln. while the η phase decomposes into the θ and δ solid solns at 1340°. The δ solid soln. dissolves about 2% of Co in Mo at room temp. The hardness of the cobalt-rich alloys was measured.

K. SOMEYA

Eutectic areas. W. WAHL. III. *Nord. Kemistmötet* (Finland) 1928, 180 3. A eutectic point appears in a quaternary system only in case all 4 components in crystallized forms are insol. in each other. If 2 compds. build mixed crystals in all proportions and these are insol. in each other a eutectic line is obtained. If 3 of the components form mixed crystals but the 4th is insol. in these, a eutectic area is obtained, which is defined by the 3 eutectic points and the 3 tertiary eutectic lines for the system. Likewise a eutectic area is obtained if the 4 components, pair for pair, form mixed crystals in all proportions, but these mixed-crystal series are not soluble in each other in crystallized form. The eutectic area in such a system takes in the 4 binary eutectic points and the four eutectic lines. The four-component system, naphthalene- β -naphthol-azobenzene-stilbene has been studied. In it the two binary systems, naphthalene- β -naphthol and azobenzene-stilbene form mixed crystals which are insol. in each other. A diagram of the results obtained together with a discussion is given. A number of natural products (rocks) are considered from the point of view of being four-component systems of the type investigated.

O. A. NELSON

Influence of cooling velocity upon eutectic structure. G. TAMMANN AND A. A. BORISCHWAR. Univ. Göttingen. *Z. anorg. allgem. Chem.* 178, 325-8(1929). With very slow cooling it is possible to effect a considerable sepn. of the two constituents of a eutectic through crystn., especially if one is much heavier than the other. Slow cooling leads to large crystals in the eutectic. Centrifuging a very slowly crystallizing eutectic results in a very considerable sepn. Eutectic compns. of the binary systems Bi-Sn, Bi-Pb, Bi-Cd, Pb-Sb and Sn-Pb were treated in this way. The liquid eutectic was placed in a furnace the temp. of which was 2-3° below the eutectic temp. Upon attainment of the eutectic temp. the alloy was cooled 2° during 2-6 hours. The quantity of metal used was 40-50 g. The sepn. of eutectic graphite in Fe-C alloys (C 3.00, Si 2.72, Mn 0.45, P 0.28, S 0.07%) is similar, but it is necessary first to break up the graphite dendrites which form a skeleton throughout the melt supporting itself in the melt. The structure of these eutectic alloys is illustrated by six photomicrographs. Similar sepn. in eutectic mixts. is found among igneous rocks, where the rate of cooling was very slow. Here the grains are almost always very large.

ROBERT F. MERRILL

Abnormal properties of eutectics of high dispersion. N. Y. AGEEV, S. A. POGODIN AND N. S. KURNAKOV. *Ann. inst. anal. phys.-chim.* (Leningrad) 4, 23-38(1928).—This article is a study of the effect of dispersion upon *elec. cond.*, *hardness* and *coeff. of linear expansion* in a eutectic mixt. Alloys of Sn with Pb, and of Ag with Cu were selected for study. The Brinell hardness tester was used. The increase in hardness of quickly chilled, as compared with slowly cooled samples is much greater for a eutectic alloy than for one of any other compn. The abnormal behavior of a eutectic mixt. is noticeable also on the diagrams of *sp. conductance* and *thermal coeff. of elec. cond.* When the alloys are annealed the difference between the slowly, and the quickly chilled alloys disappears.

REA MAIZEL

The equilibrium of some binary systems of 2,4,6-trinitro-*m*-xylene. N. N. EFREMOV AND A. M. TIKHOMIROVA. *Ann. inst. anal. phys.-chim.* (Leningrad) 4, 65-91 (1928).—The pure trinitro-*m*-xylene (I) was prepd. by recrystg. the com. product 5 times. The final product m. 180.2°. The temp. and percentage compn. by wt. of the second component in the eutectic for different systems were: I-naphthalene 76.0°, 82.4; I-acenaphthene 84.0°, 77.3; I-phenanthrene 86.0°, 73.0; I-anthracene 151.2°, 35.6; I-fluorene 100.6°, 64.5; I-*m*-dinitrobenzene 76.4°, 82.2; I-picric acid 105.8°, 78.3; I-trinitrocresol 84.6°, 82.8; I-styphic acid 141.3°, 62.5; I-teteryl 110.8°, 76.5; I-picryl chloride 73.2°, 87.0; I-1,3,5-trinitrobenzene 104.6°, 83.6; I-trinitrotoluene 75.2°, 92.0. The phase diagram indicates that I does not form compds. with any of the aromatic hydrocarbons studied.

REA MAIZEL

The system iron oxide-water. GUSTAV F. HÜTTIG AND HARRY GARSIDE. *Deut. Tech. Hochschule, Prag. Z. anorg. allgem. Chem.* 179, 49-76(1929).—The system $\text{Fe}_2\text{O}_3\text{-H}_2\text{O}$ was examd., special attention being paid to the aging of the various hydrates. The preps. examd. were: (I) ppt. of FeCl_3 soln. with NH_3 . After 6 hrs. air drying, rubbing, and 6 hrs. drying at 30° it analyzed $\text{Fe}_2\text{O}_3 \cdot 3.721 \text{ H}_2\text{O}$; repeated drying at 30° gave 1.233 H_2O ; drying over P_2O_5 at 40° gave 0.237 H_2O ; (II) mineral oxides, goethite (completely sol. in 20% HCl), $\text{Fe}_2\text{O}_3 \cdot 0.992 \text{ H}_2\text{O}$, and ruby mica; (III) product obtained by dehydrating (I) over P_2O_5 , extg. with dry acetone (0.610 H_2O) and drying over P_2O_5 *in vacuo* at 200° to 250°. The compn. became $\text{Fe}_2\text{O}_3 \cdot 0.145 \text{ H}_2\text{O}$; it was still active catalytically. It is concluded that complete dehydration of Fe_2O_3 with conservation of its activity is as yet impossible. Exptl. methods used for pressure and *sp. heat* detns. have been described previously; as a measure of the catalytic activity was taken the time (α , min.) required to liberate 100 cc. O_2 from a H_2O_2 soln. (0.200 g. Fe_2O_3 in 50 g. water, 5 cc. 30% H_2O_2 soln. added after 0.5 hr., 20°). For measurement of the chem. reactivity the no. cc. H_2S (β) was detd. with which the prepn. reacted in a specified time (0.200 g. Fe_2O_3 in tensi-eudiometer filled with H_2S). The rate of soln. of the preps. in HCl was detd. from the no. of min. (γ) required (0.200 g. Fe_2O_3 in 1000 cc. 0.5 *N* HCl at 20°, stirred). The isobaric dehydration curves of t (temp. at which $p_{\text{H}_2\text{O}} = 10 \text{ mm.}$) versus N (mols. water per mol. Fe_2O_3) are smooth hyperbolas for all freshly prepd. hydroxides independent of their initial H_2O content and typical for colloidal systems. After 3 months' aging a slight strengthening of the water-oxide bond is noticeable in lower p values. Entirely different are the t - N curves for the minerals; they may perhaps be regarded as the final stage of aging; one mol. of water is tenaciously held up to about 240°, goethite being apparently more stable than ruby mica. For the fresh preps. $\ln(p_0/p) = k/N$ (p_0 pressure for pure water, p that for N mols. water per mol. oxide) with k approx. 3.5. Better values are obtained on the assumption that all water is chemically bound, which gives a relation $k'N + N \ln(p_0/p) = k''$ with $k' = 1$ and $k'' = 5.55$. It is concluded for the fresh hydroxide gels that at least part of their water is chemically held; they show no traces of x-ray spectrum and are non-crystalline. For the heat effect of $\text{Fe}_2\text{O}_3 \cdot 1 \text{ H}_2\text{O} = \text{Fe}_2\text{O}_3 + \text{H}_2\text{O}_{\text{vapour}}$ 28,240 cal. is calcd. by Nernst's equation in the case of goethite and 26,373 cal. in the case of ruby mica. From the course of the *sp. heat* curves the rule is confirmed that the apparent *sp. heat* of water in hydrates is greater the more loosely it is held. Up to $N = 1$ ($c = 0.2249$) it runs proportional to N ; from there on it rises more steeply; below $N = 0.2$ it leaves the straight line to approach the *sp. heat* of *cryst. Fe(OH)* (0.1608). The extrapolated value from the straight line for $N = 0$ ($c = 0.175$) would be the *sp. heat* of anhyd., amorphous Fe_2O_3 . During the aging process the c values drop slightly. Qual. the activity, reactivity and soly. of the preps. are as follows. The three qualities run parallel, the preps. with low water content are the slowest to act, the activity has a max. for $N = 1$, min. between $N = 2$ and 3. A peculiar tendency of the activity to go up and down during a 55-day observation period was observed for $N = 0.783$. Less variation with time was found for $N = 3.731$. The rate of change of *sp. heat* seems to run parallel with that of activity. X-ray diagrams of goethite (dehydrated at 300°) and ruby mica

(dehydrated at 280°) showed cryst. Fe_2O_3 accompanied by amorphous material; the pptd. hydrate has no diagram after 60 days at room temp. B. J. C. VAN DER HOEVEN

Reflections on statistical thermodynamics. J. H. COBLYN. *Chaleur et ind.* 9, 527-34(1928).—C. discusses (a) moist vapors, lack of similarity of fluids and the function of the change of state, (b) vapor-tension curves, (c) mol. entropy of vaporization. He shows that even if the influence of pressure on the vol. of a liquid is negligible, it is not negligible on its calorimetric properties. S. L. B. ETHERTON

Statistical thermodynamics. J. H. COBLYN. *Chaleur et ind.* 9, 245-52(1928).—C. discusses Massieu's function, additivity of mol. heats, corresponding states, the kinetic theory, equipartition of energy and van der Waals' theory with some chem. applications. S. L. B. ETHERTON

Thermodynamics of irreversible reactions. Evolution of physical and chemical systems in time. N. A. KOLOSOVSKII. *J. Russ. Phys.-Chem. Soc.* 60, 1079-1115(1928).—The time factor is introduced as an independent variable into De Donder's thermodynamic theory of chem. reactions (*Mém. Acad. Roy. Belg.*, 9(1927)) and a series of expressions for velocity of reaction is derived from an exclusively thermodynamical point of view. Further equations are given expressing uncompensated heat of reaction in gaseous systems, which represent a generalization of the ordinary conditions of equilibrium in such systems. B. C. A.

A thermodynamic consideration of the synthetic methanol process. KENNETH K. KELLEY. Stanford Univ. *Ind. Eng. Chem.* 21, 353-4(1929). From new data, the following free-energy values for the reaction: $\text{CO(g)} + 2\text{H}_2\text{(g)} = \text{CH}_3\text{OH(g)}$ are obtained $\Delta F^\circ_{298} = -9040$ cal., and $\Delta H^\circ_{298} = -25,150$ cal. $\Delta F^\circ = -20,740 + 4500/T \log_{10} J - 0.015867T^2 + 1T$ where $T = 604$. J. H. PERKINS

The absolute zero of temperature: the specific heats of gases and deductions respecting quanta. F. H. LORING. *Chem. News* 138, 18-22(1929), cf. *Ibid* 137, 3-6(1928).—The ratio $\gamma = C_p/C_v$ is taken as Avogadro's const. multiplied by the abs. value of the abs. zero in the centigrade scale, divided by 10^{24} . This gives 6.061×10^{24} (273.194)/ $10^{24} = 1.65309 = \gamma$, agreeing fairly well with exptl. and theoretical values. A similar discussion is presented of the quantum theory. G. CALINGARI

Further studies on the thermochemical behavior of sodium hydroxide solutions. THEODORE W. RICHARDS AND LAWRENCE P. HALL. Harvard Univ. *J. Am. Chem. Soc.* 51, 731-6(1929).—The heat of diln. of NaOH-100 H_2O was measured at 16° and 20°. All this laboratory's heat capacity and heat of diln. data on NaOH were recalcd. The heat of neutralization of HCl and NaOH at infinite diln., and 20° was calcd. to be 13,650 cal. F. D. ROSSINI

The heats of dilution of sodium hydroxide, acetic acid and sodium acetate, and their bearing on heat capacities and heat of neutralization. THEODORE W. RICHARDS AND FRANK T. GUCKER, JR. Harvard Univ. *J. Am. Chem. Soc.* 51, 712-27(1929). Cf. *C. A.* 19, 2563; 15, 1844.—An improved calorimeter, which is described, was used to measure heats of diln. at 16° and 20°. Sp. heat and heat of diln. data on AcONa , NaOH and AcOH are given, and the heat of neutralization of NaOH and AcOH is calcd. as nearly 13,600 cal. at infinite diln. F. D. ROSSINI

The heat of neutralization of acetic acid. THEODORE W. RICHARDS AND BEVERIDGE J. MAIR. Harvard Univ. *J. Am. Chem. Soc.* 51, 737-40(1929).—The heat of neutralization of AcOH-100 H_2O and NaOH-100 H_2O was found to be 54,321 joules at 20°. The heat of the reaction, $\text{H}^+ + \text{OH}^- = \text{H}_2\text{O}$, at infinite diln., was calcd. to be 55,050 joules at 20°. F. D. ROSSINI

A study of the thermochemical behavior of weak electrolytes. THEODORE W. RICHARDS AND BEVERIDGE J. MAIR. Harvard Univ. *J. Am. Chem. Soc.* 51, 748-58(1929).—The heats of diln. of citric acid, sodium citrate and the sodium acid citrates in aq. soln. were measured. Data on the heat capacities and heats of diln. of the substances are given at 16° and 20°. The heat of neutralization of citric acid and the acid citrates with NaOH was measured and the temp. coeff. was calcd. F. D. ROSSINI

The calculation of the integral and differential heat of solution and dilution of potassium chloride and the molecular heat of potassium chloride solutions at great dilution. E. LANG AND J. MONHEIM. *Z. Elektrochem.* 35, 20-33(1929). L. and M. have calcd. the data from detns. at 12.5° and 25° for about 18 concns. The values are discussed and then compared with those of others. S. L. B. ETHERTON

Heats of combustion of organic compounds. M. S. KHARASCH. *Bur. Standards J. Research* 2, 359-430(1929).—The literature on the heats of combustion of org. compds. is critically reviewed. A table of "best" values for this const. is compiled covering all available information on record in the literature. A method for calcg. the heat of combustion from the structural formula of the compd. is described, and the value calcd.

according to this method are tabulated for comparison with the observed values. The comparison demonstrates that the calcd. values are sufficiently accurate for most practical purposes. The difference between calcd. and observed values seldom exceeds 1 to 2% except in cases where there is reason to doubt the accuracy of the observed value. In most cases the two values agree within the accuracy of the observed value.

3--SUBATOMIC PHENOMENA AND RADIO CHEMISTRY

S. C. LIND

The new theory of Einstein on the relation of gravitation and electricity. HANS REICHENBACH. *Z. angew. Chem.* 42, 121 3(1929).—The new theory is based on the Weyl-Eddington generalization of Riemann space, an outline of which is given. Although the phys. result of the connection between gravitation and electricity is not predicted by the theory, the importance of the relation cannot be overlooked.

H. F. JOHNSTONE

The limiting density of white dwarf stars. E. C. STONER. Univ. of Leeds. *Phil. Mag.* [7], 7, 63-70(1929).—Using Fermi statistics S. shows that under the influence of gravitational and electron "packing effects," the limiting density C of a uniform sphere of mass M , consisting of a mixt. of fully ionized atoms, is approx. given by $C = 3.85 \times 10^6 (M/M_\odot)^2$, where M_\odot is the mass of the sun. For spheres with the masses of Sirius B and O, Eridani B the limiting densities are 2.8×10^6 and 7.5×10^6 , resp. S. suggests that white dwarfs contain a core of material approaching the limiting density, the ratio of the radius of the core to the radius of the star being about 0.25.

and 0.61 for the 2 white dwarfs considered. S. believes the core to be in an almost incompressible or "quasi-liquid state," because of the congestion of the electrons. Jean's theory of the distribution of stars in the Russell temp.-luminosity diagram is discussed. It is shown that the quasi-liquid state required for stability may be attained in white dwarfs as a result of electron packing, without the necessity of assuming "jamming" of the few remaining K-ring atoms.

L. H. REYERSON

What happens during an electron jump? D. S. VILLARS. *Nature* 123, 240 (1929).—The Schrödinger theory answers the question as to what happens during an electron "jump." The electron does not jump, but at most, it undergoes a change in momentum and obeys a new force law.

Nonpolar valency binding and atomic refraction. II. FRANK V. JOHNSON, JR. *Z. Physik* 53, 380-403(1929).—See *C. A.* 23, 1874.

Quantization of the asymmetric top. H. A. KRAMERS AND G. P. ITTMANN. *Z. Physik* 53, 553-65(1929).—The method of phase integrals used for the quantization of the asymmetric top can be carried over to the quantum mechanics and gives a Lamé differential equation. The theory of the Lamé functions and their eigen-values can at once be applied to the problem of the asymmetric top. The energy levels, the transition to the symmetrical top and the case of large quantum nos. are discussed.

GEORGE GLOCKLER

Quantum mechanical dispersion formula for atomic hydrogen in the normal state. F. REICHE. *Z. Physik* 53, 168-91(1929).—A dispersion formula derived by Podolsky (*C. A.* 22, 2312) for the dispersion of at. H in the normal state is shown to be identical to the Ladenburg-Kramers formula (*C. A.* 22, 4364).

GEORGE GLOCKLER

The nonpolar bond in quantum mechanics. Confirmation from spectroscopy. W. HEITLER AND G. HERZBERG. *Z. Physik* 53, 52-6(1929).—Certain results of band spectroscopy are summarized and discussed and it is shown that certain atoms (for instance the C atom) can enter into stronger combination if they are first excited. For instance the C atom has in its normal state 1 electron pair in the L_1 shell and 2 non-paired electrons in the L_2 shell. Consequently C is bivalent in its normal state. In order for C to be quadrivalent it is necessary that one of the L_2 electrons be lifted into the L_1 shell. Then the 4 electrons are free (non-paired) valency electrons with parallel spin. This idea is tested on CN bands and it appears that quadrivalent C is in an excited (4S) state (about 1.6 v.) while the normal state is a 3P state.

GEORGE GLOCKLER

Radioactivity and quantum mechanics. J. KUDAR. *Z. Physik* 53, 61-6(1929).—Gamow's treatment (*C. A.* 23, 1047) of radioactivity by the methods of wave mechanics is somewhat faulty from a mathematical viewpoint, giving an approx. calcul. only for the decay const. Mathematical.

GEORGE GLOCKLER

Quantum mechanics and radioactivity. J. KUDAR. *Z. Physik* 53, 95-9(1929).—It is shown that the non-relativistic Schroedinger equation yields a quantum mech. description of α -ray disintegration. From the theory it follows that the α -particle can assume within the nucleus a finite set of states only. Mathematical. G. G.

Quantum mechanics and radioactivity. J. KUDAR. *Z. Physik* 53, 134-7(1929). cf. preceding abstr.—The three-dimensional case is discussed. The results are analogous to the one-dimensional case. A remarkable result is that an α -particle with pos. energy (i. e., in an unstable state) can exist within a nucleus only when the radius (where the Coulomb forces hold) is not too small. Mathematical. G. G.

Nernst's hypothesis of the creation of radioactive elements on the basis of wave mechanics. J. KUDAR. *Z. Physik* 53, 166-7(1929).—Gamow's wave-mech. theory of radioactive α -particle decay states that a given α -particle has a certain probability for leaving the nucleus. K. now states that it is a necessary consequence of wave mech. considerations that there also should exist a certain probability for the reverse process of an α -particle entering the nucleus. The α -particle must have an appropriate energy while approaching the nucleus. The probability of addn. of an α -particle to a given nucleus depends upon the decay constant of the resulting nucleus (*C. A.* 23, 1047).

GEORGE GLOCKLER

Quantum theory and radioactive disintegration. G. GAMOW. *Z. Physik* 53, 601-4(1929); cf. *C. A.* 23, 1565, 1807.—Polemical. Reply to remarks made by Laue (*C. A.* 23, 1565), regarding G.'s mathematical treatment of the appropriate wave equation (*C. A.* 23, 1047).

GEORGE GLOCKLER

New investigations of the penetrating radiation of H₂. E. STRINKE. *Z. Physik* 48, 647-89(1928); *Science Abstracts* 31A, 700.—A new app. was employed, with an ionization chamber filled with CO₂ under pressure, and with an Fe armor built up in sections, by means of which thicknesses of 4, 8 and 12 cm. of Fe can be obtained, with

different angles of complete or partial opening. The drift of the electrometer, due to radioactivity in the interior of the instrument, was much smaller than in previous ones, only 0.2 J. Intensity, absorption and direction measurements were made near sea-level, and at 1600 and 2500 m. Conclusion: The penetrating radiation is not homogeneous; the smallest absorption coeff. in Pb which has been measured is $\mu = 0.0042 \text{ cm.}^{-1}$, this radiation being about 100 times as penetrating as normal radium radiation, wave length estd. as 0.07 X. U., corresponding to an energy level of 177 million v., which approaches that which would be theoretically set free if matter were transformed into energy. Scattered energy is also important, and affects the ionization; scattering takes place in air and in Fe, but apparently the amt. of it in Pb is small. The daily variations in the intensity were studied for 4 days at 2500 m. elevation, and were found to be considerable though smaller than those measured by other investigators at the same height. Difficulties were found in explaining the effect of barometric height on the intensity.

H. L. D.

Yield in atomic disintegration experiments. W. BOTHE AND H. FRÄNZ. *Z. Physik* 53, 313-6(1929); cf. *C. A.* 22, 1902.—Discussion of differences in results obtained by B. and F. and Kirsch and Pettersson at Vienna (cf. *C. A.* 22, 1271).

GEORGE GLOCKLER

Two simple methods of purifying radium emanation. WM. G. MORAN. *Phil. Mag.* [7], 7, 399-404(1929).—A simple app. for the purification of Rn is described, it is low in cost and easy to operate. Liquid air is not needed and the removal of water vapor is unnecessary. One method ignites the O and H with a hot CuO filament, which also oxidizes the excess H. The other method uses a spark to unite the O and H while the excess H passes through a heated Pd tube. The Rn is pumped from soln. into a small purifying tube and from there forced directly into the thin-walled capillary. The Rn may be withdrawn and collected over Hg at any stage in purification. The concn. attained compares favorably with that obtained with complicated installations.

L. H. REYERSON

The separation of ionium from Fergan ore. A. N. PILKOV. Bureau of Weights and Measures. *J. Russ. Phys.-Chem. Soc.* 60, 835-41(1928).—The ore contained 0.17% Ce_2O_3 and traces of Th besides Ca, V, U, Cu, Mg, Mn, Fe and Al. U and V were removed according to the method of Meyer and Hauser ("Die Anal. der Selt. Erden," 1912, p. 237). $\text{H}_2\text{C}_2\text{O}_4$ was then added; the resulting ppt. of Ce oxalate contained adsorbed Io. The α -ray activity of this prepn. remained const. for 6 months while the intensity of penetrating rays, originally very small, further declined with time. The radioactivity was increased by igniting the oxalate to CeO_2 . The β and γ radiation is due to traces of other elements not related to Io. A scheme for the analysis of the ore is given.

B. SOYENKOFF

The counting of scintillations produced by α -particles I. J. CHARITON AND C. A. LEA. Cambridge Univ. *Proc. Roy. Soc. (London)* A122, 304-19(1929).—An app. is described which produced regular point flashes of light of known spectral constitution, the energy of the flash and the duration being controlled. The min. radiation visually perceptible was found to be 17 quanta of green line ($\lambda = 0.5\mu$) for trained observers and 30 for untrained. The effect of the duration of a flash on its perceptibility showed that for flashes of duration less than $1/100$ of a sec. the energy in the flash only was important and not the duration. The sensitivity of the observer was considerably increased under the influence of a tonic drug. II. The determination of the efficiency of transformation of the kinetic energy of α -particles into radiant energy. *Ibid* 320-34.—A detn. was made of the radiant and luminous efficiencies of various Zn sulfides when bombarded by α -particles. Surprisingly high values were obtained, namely, about 25 and 12%, respectively, the value previously reported for the radiant efficiency being about 1.5%. These high values are, however, in agreement with those calcd. from data concerning radioactive luminous paints and they were checked by two rough methods. III. Practical applications. *Ibid* 335-52.—The question of how the amt. of light entering the eye from an individual scintillation affects the no. of scintillations observed was investigated. Scintillations were observed with the naked eye, and it was found that a smaller fraction of the light from a scintillation produced a visual sensation when the eye was unaided than when a microscope was used. A partial explanation was given in view of the difference in the sizes of the retinal images in the two cases. The velocity of the slowest α -particle capable of producing a visible scintillation was measured and found to be 0.13 of the velocity of the α -particles from Ra C, in good agreement with previous results by Rutherford. The exptl. results obtained in all three parts of the paper are summarized and discussed.

MARIE FARNWORTH

Relative velocities of the α -particles emitted by certain radioactive elements. G. C. LAURENCE. *Proc. Roy. Soc. (London)* A122, 543-51 (1929).—The velocities of the α -particles from Th C and C' and Ra F have been measured by comparison of the magnetic deflections of the particles produced by a const. magnetic field with that of the α -particles from Ra C'. The sources are placed in a box, placed between the poles of an electromagnet, and contg. a photographic plate. The α -rays from different sources fall on different parts of the plate, the lines produced on the plate are measured by a microphotometer, the radii of curvature of the deflected beams are calcd. and the relative velocities thus obtained. The difficult measurement of the strength of the magnetic field is thus avoided. The velocity ratios of α -particles are found to be Ra F:Th C:Ra C':Th C' = 0.8277:0.8885:1.0000:1.0679 with a probable error of 0.05%. Taking the velocity of the α -particles from Ra C' as 1.923×10^9 cm./sec., the velocities of the α -particles from the other elements are Th C 1.709×10^9 , Th C' 2.054×10^9 , Ra F 1.592×10^9 cm./sec. W. WEST

Investigation of the ranges of the long range α -particles from Th C and Ra C using an expansion chamber. R. R. NIMMO AND N. FEATHER. *Proc. Roy. Soc. (London)* A122, 608-87 (1929).—The relative merits of the scintillation and expansion methods for measurement of ranges are discussed, and descriptions given of the use of the expansion chamber. Conclusion: Th C gives 2 groups of α particles having extrapolated ionization ranges of 11.70 and 9.90 cm. in standard air. Some tracks of greater range than 12.5 cm. were found and these are also thought to originate in α -particles from Th C. Ra C has a group of α -particles of range 9.16 cm., but tracks are also found of particles with ranges between 7.5 and 12.5 cm. The no. of long tracks is too small to show definitely whether these particles are emitted in groups of const. velocity but there are strong indications of groups of ranges 8.1 and 11.0 cm. W. WEST

Experimental study of the passage of α -rays through matter. SALOMON ROSENBLUM. *Ann. phys. [10], 10*, 408-71 (1928), cf. C. A. 22, 724. R. has continued, with improved app., previous investigations on the retardation of α rays upon passing through various metals. (1) α -rays undergo on traversing metals, a loss in velocity

according to the law: $N = K \left(1 - \frac{V}{V_0}\right) \left[1 - \log \left(2 - \frac{V}{V_0}\right)\right]$, where K is a const. characteristic of the metal traversed and a function of its at. no., V the max. per unit area of the screen and V/V_0 the ratio of final to initial velocity of the α rays from Th C'. (2) The curve of the values $\frac{dE}{dV} = \frac{m V_0^2 V}{K V_0^2} \frac{1}{2 - \frac{V}{V_0}} \frac{1}{1 - \log \left(2 - \frac{V}{V_0}\right)}$

where E is the active force of the α particle as a function of V/V_0 , has the same general form as the curve of Bragg, and the maxima of the 2 curves coincide. (3) The formula $X_p = K 36.3$ is proposed for the calcn. of the total path of α particles from Th C' in metals; the values so calcd. accord well with those found by other methods. (4) Two groups of α -rays of unit charge with approx. the same speed as the doubly charged particles were observed in the radiation from the active deposit from Th C' by the photographic method. (5) The expression $\frac{N}{\sqrt{N+4}}$ is proposed for the per cent of

retardation per atom; this formula more nearly conforms to exptl. results than those previously proposed, and the errors are less systematic. (6) An approx. accord has been found between the Bohr theory and the retardation of α -rays upon passing through screens of metals of low at. no. (7) Incidentally, it has been observed that certain substances (notably vaseline), become fluorescent under the impact of α particles and that certain metallic screens, when placed near strong sources of Th B, exhibit impressions corresponding to the image of the source. L. A. SARKER

The heat of the β - and γ -radiation of radium. A. DORANIALSKA. *Radiat. intern. acad. Polonois* A1928, 459-70; cf. C. A. 22, 1271, 23, 1888. —The heat effect of the β - and γ -radiation of Ra is detd. by means of an adiabatic microcalorimeter constructed by Swietoslowski and the author (cf. C. A. 22, 514). RaBr_2 equiv. to about 1.1 mg. Ra is used throughout. The heat is absorbed in Cu, Ag, Pb and Wood alloy calorimeters whose absorbent masses were 17.72, 27.42, 32.13 and 37.85 g. (sq. cm.), resp. the optimum heat capacity of the system was 1-4 cal. with temp. variations from 0.6 to 0.15°. The results found are: $Q_1 = 0.734$, $Q_2 = 0.690$ and $Q_3 = 0.687$ cal. per hour, where $Q_1 = q_\alpha + q_\beta + q_\gamma$, $Q_2 = q_\alpha + \frac{1}{2}q_\beta + \frac{1}{2}q_\gamma$, and $Q_3 = q_\alpha + \frac{1}{4}q_\beta + \frac{1}{4}q_\gamma$, q_α , q_β , q_γ being the heat values of α -, β - and γ -radiation, resp. Calcd. for 1 g. Ra

the heat effects are 132, 12.0 and 16.6 cal. per hr. for α -, β - and γ -radiation, resp. Thus the heat effect of the β -radiation is only 9.1%, that of the γ -radiation 12.4% of that of the α -radiation. These values, too low in regard to the theoretical ones, are due to the inclusions of Ra D and Ra E in the analyzed salt.

γ -Radiation of the radioactive elements. E. CHALFIN. *Z. Physik* 53, 130-3 (1929).—The production of γ -rays is nowadays assumed to take place in the following manner: After an electron (or in a few cases an α -particle) has left the nucleus, there follows a rearrangement of the remaining portions of the nucleus. This rearrangement is accompanied by radiation (γ -rays) whose energy equals the difference of certain nuclear energy levels. C now supposes that the larger the emitted energy (the harder the γ -rays) the more stable the resulting radioactive element should be. In other words, there should be a connection between the hardness of the emitted γ -ray and the life period of resulting radioactive element. Such seems to be the case. Furthermore, it is known that the γ -rays originate with the resulting radioactive element or after the rearrangement of the outer electron shells has taken place. There is then a certain period of retardation between the act of emission of the α - or β -particle and the γ -ray. This corresponds to the existence of an intermediate element.

The γ -rays of radium. J. A. GRAY. *Nature* 123, 241-2 (1929).—An outline of the method and the conclusions reached in the detn. of γ -ray wave lengths. These conclusions have been used in making an examn. of the results of cosmic ray expts.

GEORGE GLOCKLER

Is there a stable radium isotope in barium minerals? OTTO HAHN AND KARL DONAT. Kaiser Wilhelm Inst., Berlin Dahlem. *Z. physik. Chem., Abt. A*, 139, 143-50 (1928).—In view of the fact that Ra has an even at. no. and of the frequent occurrence of the alk. earths on the one hand and of U and Th on the other, expts. were performed to det. whether or not there existed in Ba minerals a stable Ra isotope independent of the radioactive isotopes which appear as disintegration products of U and Th. 220 kg. of BaBr₂ was concd. so that the concn. of the hypothetical Ra would be about 500,000 times its original concn. and the concentrate examd. for Ra spectroscopically. No Ra line was obtained. There was a concn. of radioactive Ra, as detd. by the electroscope but this did not reach a spectroscopically determinable amt. There is, therefore, no evidence for the existence of a stable Ra isotope in Ba minerals in an amt. greater than 2×10^{-10} g. per g. of Ba.

W. WEST

Detection of the isotopes of lead by the band spectrum method. SIDNEY BLOOMENTHAL. Univ. of Chicago. *Science* 60, 220 (1929).—A comparison was made of the band spectrum of ordinary Pb with at. wt. 207.2 contg. the isotopes 208, 207 and 206, and that of U Pb with at. wt. 206.1. The results are in good agreement with the theory on the basis of PbO as the emitter. The sepn. theoretically expected between the lines due to Pb₂₀₆O and Pb₂₀₇O near the head of the 5578.3 band is -0.37 wave no. The av. measured value was -0.43 wave no. The lines from the mols. of the lighter isotope are displaced toward lower frequencies with respect to those from the mols. of the heavier isotope.

H. F. JOHNSTONE

Contribution to the study of the isotope of lead. MME. B. PERRETTE-MONTAMAT. *Ann. phys.* [10], 10, 349-407 (1928). A comparative study has been made of the phys. properties of 2 carefully purified samples of Pb of different origins and at. wts. (one being ordinary Pb of at. wt. 207.2, the other extd. from pitchblende, with an at. wt. of 206.14) as follows: (1) Spectroscopic measurements of Merton relative to the difference of λ for a given radiation in 2 isotopes have been extended, by using an arc *in vacuo* as light source, and an interferential etalon of Fabry and Pécrot assocd. with a spectrograph having 2 quartz prisms. Results confirm the direction of the difference previously found, with diminution of the difference toward the ultra-violet; it is of the order of 0.007 Å. Å. for the Pb ray 4058, with an accuracy of the order of 0.0008 Å. Å. (2) Densities and solubilities. (a) The density of the ordinary metallic Pb was 11.336 ± 0.0004 at 0°, and that of the Pb from pitchblende was 11.278 ± 0.0004; this confirms the law of the constancy of at. vols. for isotopic elements. (b) The densities of the crystd. nitrates at 0° were 4.536 ± 0.0005 for ordinary Pb, and 4.523 ± 0.0005 for the Pb from pitchblende; these are new results and show that the mol. vols. of isotopic nitrates are also const. (c) The densities of the satd. solns. of the nitrates did not give satisfactory results, but confirmed the direction of the difference. (3) The indices of refraction of the nitrates were measured by the immersion method of Fabry; but in spite of the great sensitivity (of the order of 0.00015) no difference could be detected. The value found for n was 1.78185 at 10° for the ray 5890 Å. Å.

L. A. SARVER

Probability of excitation by electron-impact in neon. R. D'E. ATKINSON. *Proc. Roy. Soc. (London)* A122, 480-42(1929).—Results of Townsend and McCallum (C. A. 22, 2319) are analyzed by a new method derived from the quantum theory and it is shown that the mean probability of inelastic collisions is about 5%. This represents the sum of the probabilities of all the transitions that can occur at any given energy.

GREGG M. EVANS

Three-dimensional motion of an electron in the field of a non-neutral atom. M. A. HIGBAR. *Phil. Mag.* [7], 7, 31-52(1929).—On the basis of classical theory H. deduces mathematical expressions for the motion of an electron under the effect of an elec. doublet (neutral atom) and at the same time acted upon by a central charge or force inversely proportional to the square of the distance from the doublet itself.

L. H. REYERSON

Polarization of electron waves. E. RUPP. *Z. Physik* 53, 548-52(1929).—Twice-reflected electrons (120, 240, 380 v.) show no selective reflection depending on the position of the second reflector. Single Cu crystals were the reflecting surfaces. Electrons in a magnetic field behave as they do in a field-free space.

G. G.

The thermionic emission constant A. R. H. FOWLER. *Proc. Roy. Soc. (London)* A122, 36-49(1929).—The main object of the paper is to apply Nordheim's theory of the emission coeff. of electrons from metals so as to explain the remarkable relation between the consts. A and X of the thermionic emission formula, first recorded by Richardson and recently reformulated by Du Bridge. This theory regards the emission as due to the passage of electrons through simple surface potential steps and double layers, to be calcd. according to the wave mechanics. Conclusion: The theory gives a completely satisfactory account of the facts whenever it can be properly applied. The necessary conditions for its proper application are formulated. Certain apparent discrepancies in abs. magnitude between the observed and theoretical values of A are left outstanding and possible explanations of these are discussed. Though their precise cause cannot yet be specified they can certainly be explained and their existence is in no way antagonistic to the main theory.

MARIE FARNSWORTH

A case of the direct transition from ohmic to spark conduction in highly ionized gases at high pressure. RUDOLF THALLER. *Univ. Hamburg. Physik. Z.* 30, 59-61(1929).—A case is reported in which the current-voltage curve in an ionization chamber is not of the usual type, but shows a direct change from ohmic conduction to a spark discharge, with no satn. current intervening. The set-up was as described in *Physik. Z.* 29, 841-6(1928).—There was const. increase in ionization current with increasing voltage up to 35 kv., after which there was a rapid increase until, at 50 kv., there was a loud columnar discharge between the electrodes. This observation negates some of the work described in *loc. cit.*

LOUIS WALDBAUER

Ion rays. JOHANNES KAHRA. *Univ. Muenster. Ann. Physik* [5], 1, 135-66(1929).— $PbBr_2$, PbI_2 , and PbF_2 emit only neg. ions. This confirms the hypothesis that only that ion is emitted which migrates during electrolysis. The emission decreases with time and becomes const. after 20-30 mins. At 500°, pos. emission also takes place, which may be caused by the Pt wire or the decompn. of the 1st salt. Gases which penetrate into the salt loosen its lattice and increase emission. This is in agreement with the Smekal-Hevesy theory. $KClO_4$ does not emit below its m. p. (368°). Above this temp. it emits positively and to a slight extent negatively. KNO_3 and $NaNO_3$ also show no emission below the m. p. Glass emits only pos. ions. By increasing the temp., currents of 10^{-7} amp. may be obtained. The emission changes with time and reaches a const. final value.

FRANK URBAN

Time change of emission of ion rays. O. BIRKENHAGEN. *Univ. Muenster. Ann. Physik* [5], 1, No. 1, 157-68(1929).— CdI_2 in soln. transferred to a Pt wire and heated to a const. final emission value retains this value indefinitely in a vacuum. After the salt has come into contact with air, its emission is increased considerably. This is due to atm. moisture. Molten CdI_2 gave the same results. Sublimed CdI_2 acted differently. After heating it could be regenerated in a vacuum as well as by dry air, providing sublimation took place in air. Sublimed TlI_3 resembled CdI_2 . K_2CO_3 and $PbCl_2$ could be regenerated by moist air, but not $AgCl$. These facts can be satisfactorily explained by Smekal's theory.

FRANK URBAN

Probe and radiation measurements in the copper arc. W. B. NOTTINGHAM. *J. Franklin Inst.* 207, 299-314(1929).—A Langmuir probe is used in a study of normal arc between Cu electrodes to det.: (1) av. energy of electrons in the arc, (2) distribution of potential along the arc stream, and (3) pos.-ion concn. in central portion of the arc with different currents flowing. Variations in intensity of certain lines of Cu spectrum were measured for changes in arc current.

M. McMAHON

Diffraction of electrons at ruled gratings. B. L. WORSNOP. King's Coll., London. *Nature* 123, 164-5(1929).—A "collimated" beam of electrons from a coated filament was sent at a glancing angle of approx. 1° on to a ruled grating from which all light was carefully excluded. The photographic plate showed a diffracted line on each side of the directly reflected line. W. shows that the results obtained by Rupp, in which no diffracted line appeared on the small angle side of the diffracted beam, can be explained by the very small glancing angles which he used. W. W. STIFLER

Secondary electron emission from insulators. H. DAENE AND G. SCHMERWITZ. *Z. Physik* 53, 404-21(1929).—It is known from an observation by Wehnelt (*C. A.* 23, 333) that the secondary emission of electrons from an insulator decreases suddenly at a definite angle between primary beam and reflector. Klemperer (*C. A.* 22, 1903) and Joffe (*C. A.* 22, 2876) have attempted theories which are subjected to exptl. test and found wanting. A new theory assuming a neg. potential region on the surface of the reflector is developed and appears satisfactory. GEORGE GLOCKLER

Reflection of electrons on a surface where a potential discontinuity exists. O. KLIM. *Z. Physik* 53, 157-67(1929).—The problem of the reflection of an electron on a surface where a potential discontinuity exists is attacked by the methods of Dirac dynamics. According to the theory for large potential discontinuities the electrons have a probability to traverse the region of discontinuity and will arrive on the other side with neg. kinetic energy. This is a particularly striking example of the difficulty mentioned by Dirac which arises in relativistic quantum mechanics even in a purely mech. problem where no radiation processes are involved. GEORGE GLOCKLER

The structure of an electron. I. USAKI KAKINUMA. *Proc. Phys.-Math. Soc. Japan* [3], 10, 235-42(1928).—A mathematical discussion. C. H. BADGER

Sparking potential at pressures less than atmospheric. F. KLINGELFUSS. Basel. *Z. Physik* 53, 154-6(1929).—K. calcs. the elementary charge from the min. sparking potential and gives the value to 7 significant figures. GEORGE GLOCKLER

Wilson cloud chamber with carbon tetrachloride. K. PHILIPP. *Z. Physik* 53, 100-1(1929).—In order to exclude H atoms from the H_2O usually used in a Wilson cloud chamber during expts. on at. disintegration it is proposed to replace H_2O vapor by CCl_4 . The expts. tried show the new method to be very suitable. G. G.

Recombination spectra of ions and electrons in cesium and helium. F. L. MOHLER AND C. BORCKNER. *Bur. Standards J. Research* 2, 489-500(1929); cf. *C. A.* 22, 1101.—Thermionic discharges in Cs and He, adjusted to give strong continuous bands, were measured spectrophotometrically for their intensity distribution. Probe wire measurements were made of the elec. conditions. The results are explained on the basis of simple recombination. The probability of recombination is proportional to $1/\sqrt{v} - \kappa$. The relative values of probability of recombination as a function of electron energy are independent of discharge conditions. WALLACE R. BRODE

The attachment of electrons to the molecules hydrochloric acid and ammonia. V. A. BAILEY AND A. J. HIGGS. *Phil. Mag* [7], 7, 277-80(1929).—The method for the study of the attachment of electrons to mols. described (*C. A.* 20, 91) is applied to HCl and NH_3 . The results serve to indicate a certain correspondence between the probability of attachment to a given mol. and its elec. moment as deduced from variations of dielec. const. with temp. L. H. REYERSON

Production of hydrogen atoms by slow electrons. K. E. DORSCH AND H. KALLMANN. *Z. Physik* 53, 80-91(1929).—H atoms are formed in a primary electron impact with H_2 mols. when the electrons have a velocity of about 11-12 v. The effect increases considerably at 16 v. H_2 ions cause the formation of H atoms in a secondary act: $H_2^+ + H_2 \rightarrow H_3^+ + H$. A few H atoms can be detected below the resonance potential. But this point has not been investigated thoroughly. The probability of H-atom formation by exciting the H_2 mol. with 3- or 4-volt electrons to such high vibrational states that disocn. into atoms would result is very small. G. G.

The effects of an homologous series of amines on the mobilities of ions in hydrogen gas. LEONARD B. LOEB AND KARL DYK. *Proc. Natl. Acad. Sci.* 15, 146-56(1929).—Because of the measurements obtained with NH_3 in air and in H_2 in the study of the mobilities of ions in gaseous mixts. (cf. *C. A.* 21, 1222), further study was made with methylamine and propylamine. The results for pure methylamine (1) were 0.494 cm./sec. for + ions and 0.535 for — ions per v. cm. and in pure propylamine (2) at 75 mm. vapor pressure were, resp., 0.243 and 0.257 cm./sec. per v./cm. when compared with the accepted standards of air of 1.4 cm. sec. and 1.8 cm./sec. per v./cm. for + and — ions, resp. Curves are shown for H_2 + (1), for H_2 + (2) and for NH_3 in H_2 + (1) mixts. (2) in small traces adds to both + and — ions, producing a very great initial decrease of the mobility. The addn. of the amine was surprising, as NH_3

like compds. are not expected to attach to charges. The addn. of (1) in traces does not raise or lower the + mobility, while the — ion mobility is lowered considerably. Thereafter increasing amts. of the amine differ comparatively little from Blanc's law curves. Certain results obtained in this study indicated 2 mobilities could be observed for ions of the same sign in a gas at once but the authors show that such observations are false.

C. H. BADGER

Mercury lamp and radium as ionizers. Effect on electric spark. W. ROGOWSKI AND R. TAMM. *Arch. Elektrotech.* 20, 107-14(1928); *Science Abstracts* 31A, 721. — By using a cathode-ray oscillograph (*Arch. Elektrotech.* 18, 513-24(1927)) and app. similar to that previously employed (*Arch. Elektrotech.* 19, 235-56(1928)) an investigation was made of the effect of the light from a Hg lamp and of the radiation from Ra on the potential required to produce a spark between metal electrodes in air. It is shown that the Hg lamp used produced about the same effect as 7 mg. of Ra, both being about 10 cm. from the spark gap.

H. L. D

Electric breakdown in gases. W. ROGOWSKI. *Arch. Elektrotech.* 20, 99-106 (1928); *Science Abstracts* 31A, 715. — Various phenomena in connection with the elec. breakdown of gases are shown to be very difficult, if not impossible, to explain by means of Townsend's theory of the spark discharge. The effects are discussed in relation to ionization by impact and space charges. It appears probable that a satisfactory theory of elec. breakdown in gases must take account of space charge effects.

H. L. D

Electron scattering in helium. E. G. DYMOND AND E. E. WATSON. *Cambridge Proc. Roy. Soc. (London)* A122, 571-81(1929). In the previous expts. (*C. A.* 22, 1275) the curves relating the intensity of scattering of electrons by the atoms with angle of scattering were found to have sharp maxima, suggestive of diffraction maxima, as might be expected if the motion of electrons is governed by wave mechanics. This effect has not been confirmed in the present work, employing essentially the same method, and the maxima previously observed are now attributed to reflection of part of the initial electron beam at the charged glass walls into the receiving slits. The velocity distribution of the scattered electrons for a given angle of scattering and the angular distribution for given incident velocity are reported. At a const. scattering angle for each initial velocity maxima appear due to elastic collisions, and in addn. to excitation and ionization of the atom, resp. Ionization is at a max. with respect to excitation for incident electron velocities of about 200 v. The ratio of inelastic to elastic collisions increases with the incident velocity. The observed angular distribution curve for fixed electronic velocity for scattering in He agrees in form with Born's theoretical curve for H₂ calcd. for a somewhat lower voltage than was used in the He expt.

W. WEST

Photoelectric behavior of mercury during transition from the liquid to the solid state. MARGARETE GRÖTZMANN. *Ann. Physik* [5], 1, 49-73(1929). — The total photoelec. emission of Hg was found to be const. during transition through the m. p. Irrespective of light an elec. effect was noticed at the m. p. It seemed to be due to the formation of H vapors.

FRANK URBAN

Electrolytic manufacture of photoelectric cells and their application. L. MAEDEN AND E. ROSTAS. *Forsch. Lab. Tungstam Verrinigten Glühlampen und Elektricitats A. G., Ujpest.* *Z. tech. Physik* 10, 52-7(1929). — R. J. C. VAN DER HOEF

Directions of photoelectrons. PIERRE AUGER. *Compt. rend.* 187 1141-2(1928); cf. *C. A.* 22, 2317, 23, 1050. — Expts. on Mo similar to those previously performed with W have been made. Comparative Table:

Exciting Radiation	K α (0.21 A. U.)	Mo K α (0.21 A. U.)
	99°	
cos	0.313	0.169
"	3.3	1.97
"	1.31	1.32-1.41

L. D. ROBERT

Photoelectric effect of allotropic modifications of tin. A. GORTZ. *Z. Physik* 53, 494-525(1929). — The photoelec. effect is measured on molten Sn and on 2 of its allotropic modifications (β and γ tin). Photo-emission is independent of temp. as long as no change in phase occurs. A change in phase causes a change in intensity and in long wave length limit in the sense that the denser phase has the larger work function as with thermionic emission. The long wave length limits are: molten tin $\lambda_{2925} = 10$ A. U.; hexagonal (γ) Sn $\lambda_{2930} = 10$ A. U. and tetragonal (β) Sn $\lambda_{2740} = 10$ A. U. From the photoelec. m. p. curve it is shown that the hexagonal modifica-

tion is unstable below 200 20°. The efficiency (no. of electrons emitted per radiation absorbed) is discussed.

GEORGE GLOCKLER

Photoelectric emission and thermionic emission once more. EDWIN H. HALL. *Proc. Natl. Acad. Sci.* 15, 126-7(1929).—H. questions the conclusions of DuBridge that the photoelectric and the thermionic work functions of out-gassed Pt are equal within the limits of exptl. error (cf. *C. A.* 22, 1274) and also like conclusions of Warner for out-gassed W (cf. *C. A.* 21, 2424).

C. H. BADGER

Theory of galvanomagnetic effects. R. PEIERLS. Leipzig. *Z. Physik* 53, 255-66(1929).—It is shown that refinements added by Bloch (*C. A.* 23, 1564) to Sommerfeld's theory of electron cond. in metals (*C. A.* 22, 4347) give qual. correct statements concerning the galvanomagnetic effects. Especially does the new treatment give the 2 signs of the Hall effect and the order of magnitude of the resistance change of a conductor when placed into a magnetic field.

GEORGE GLOCKLER

Susceptibility and change of resistance of metals in a magnetic field. F. BLOCH. *Z. Physik* 53, 216-27(1929).—The paramagnetic behavior of electrons in a metal is investigated theoretically on the assumption that the conduction electrons are not free but are acted upon by a periodic force. It is further known that the normal resistance change suffered by metals in a magnetic field can be understood, at least as to order of magnitude, if one considers not only the Lorentz force acting upon the electrons but also the orientation they must suffer due to their intrinsic spin. Cf. *C. A.* 23, 1564 and Sommerfeld, *C. A.* 22, 4347.

GEORGE GLOCKLER

Magnetic moment of lithium atom. D. A. JACKSON. Oxford. *Z. Physik* 53, 458(1929).—Remark concerning Taylor's detn. (*C. A.* 23, 1568) of the magnetic moment of Li. T. claimed that the magnetic moment of the Li Kernel must be less than $\frac{1}{2}$ of the Bohr magneton. J. now remarks that the magnetic moment of the nucleus must be vanishingly small compared with the magnetic moment of an electron (in the ratio of 1:4000 of their masses).

GEORGE GLOCKLER

Magnetic moments of H-like atoms. F. B. PIDDUCK. Oxford Univ. *Nature* 122, 925(1929).—Polemical (cf. Breit, *C. A.* 23, 1348).

ALBERT L. HENNE

Evaluation of Debye-Scherrer x-ray pictures. G. KETTMANN. *Z. Physik* 53, 198-209(1929).—A graphical method is developed to det. the lattice const. from Debye-Scherrer pictures.

GEORGE GLOCKLER

X-ray tables. K. HERMANN. *Z. Krist.* 68, 288-98(1928).—A tabulation of all the space groups shows whether reflections are present or absent for all possible crystallographic planes.

L. S. RAMSDALL

Absorption of x-rays. H. R. ROBINSON AND C. I. YOUNG. Univ. College, Cardiff. *Nature* 123, 203-4(1929).—Attention is called to the inadequacy of the usual theories of x-ray absorption, since the "partial" absorptions of individual electron groups and sub-groups vary in a very complicated fashion with the wave length. The possible contributions in this field that might result from "magnetic spectrometry" of the secondary cathode rays from the absorber are outlined. This method has already yielded the result that the 2 K electrons of a Zn atom absorb as much, if not more, x-radiation (wave length 0.56 A. U.) as the 8 L electrons of H, although according to previous theories the L electrons of H should absorb from 4.8 to 5.2 times as strongly as the Zn K electrons.

W. W. STIFLER

X-ray absorption and valency. W. B. MOREHOUSE. *Phys. Rev.* 29, 924 (1927); cf. *C. A.* 21, 2223.—The absorption of heterogeneous x-rays by an element depends on its valency; the effect may differ for different wave lengths. If the screening const. changes, the absorption coeff. will change. With valency there must be a slight change in the electronic configuration of the atom.

B. C. A.

A new relation concerning x-ray absorption limits. S. BJÖERCK. *Z. Physik* 53, 228-33(1929).—A new empirical relation is given connecting the various absorption limits or x-ray terms one with the other. For instance, for elements from Mn (25)

to I (53) the M and N levels are connected by the relation $M(\text{III}) = [L(\text{III}) \sqrt[3]{M(\text{V})}] / (11.05)$ and others. The theoretical significance is not given.

GEORGE GLOCKLER

Secondary absorption edges in x-rays. B. H. RAY. *Nature* 122, 771-2(1928).—Nuttall examd. the x-ray absorption spectra of simple compds. like KCl and found 6 absorption edges both for the K and Cl atoms, all of which lie on the short wave length of the primary K-limit. Neither the valency nor the ionization theory adequately explains these absorption edges. Ray explains the observed phenomena as follows: In the ordinary absorption phenomena, the energy in the incident radiation is utilized in removing an electron from one of the energy levels to levels beyond the periphery of the atom. Radiation of higher frequencies is also absorbed and the

excess energy utilized in imparting kinetic energy to the ejected electron. In explaining the secondary absorption, it is assumed not only that a quantum of radiation can be absorbed by a single electron in an atom but also that the same quantum may be absorbed successively by 2 or more electrons occupying different energy levels. Those quanta which thus successively remove 2 or more electrons will be selectively absorbed, and will appear as absorption edges on the shorter-wave-length side of the primary K-limit. An example is given in explanation. L. L. QUILL

Estimation of the size of particles by means of x-rays. RUDOLF BRILL. *Z. Krist.* 68, 387-403(1928).—A comparison of the methods of Scherrer and of von Laue for detg. the size of small particles from the broadening of the spectral lines. The former method is useful only for relatively small particles with strong absorption. L. S. RAMSDELL

K x-ray levels of light elements. V. DOLEJSEK AND G. P. PESTRECOV. *Z. Physik* 53, 566-73(1929).—The ν/R values (ν = term value, R = Rydberg const.) can be represented empirically as a function of at. no.: $\nu/R = aN + bN^2 + cN^3 + dN^4$, where a , b , c and d are consts. and N is at. no. (from 12 to 30). The differences between the calcd. and exptl. values show periodic fluctuations. GEORGE GLOCKLER

Scattering of x-rays on graphite. W. EHRENBURG. *Z. Physik* 53, 234-6(1929). The Compton effect on graphite shows only the unmodified and the Compton line. E. cannot obtain any other scattered radiation as has been reported by Davis and Mitchell (*C. A.* 23, 765) who obtained 3 other lines which they ascribed to an excitation of the C atoms by the incoming quanta on the order of a Raman effect. G. G.

Use of the under-water spark with the Hilger sector photometer in ultra-violet spectrophotometry. H. J. McNICHOLAS. *Bur. Standards J. Research* 1, 939-49(1928).—The advantage of high-voltage discharge under water over arcs and sparks in air or other gases lies in the continuity and uniformity of its spectrum. This is most suitable for quant. spectrophotometric measurement and enables the accurate location of sharp absorption bands. The general theory of this method and a description of the app. have been given in *Bur. Standards, Sci. Paper* No. 440. M.'s description of the improved source of spark is intended for those contemplating the design and installation of similar equipment. The spark terminals are inclosed in a hard-rubber box, through which a stream of distd. water circulates. External adjustments are provided for the length of the spark gap and its position relative to the axis of the optical system. The effect of the dispersion introduced by the biprism and wedges of the sector photometer is discussed in its relation to the spark adjustment. M. suggests certain modifications in the photometer construction. A. J. MONACE

Broadening of spectral lines. B. TRUMPF. *Z. Physik* 53, 57-60(1929). The following causes may contribute to the width of a spectral line: (1) Doppler effect, (2) effect of inter-mol. fields, (3) dampening of radiation, (4) broadening due to impact, and (5) coupling factor. Another effect may be the interaction of radiation and kinetic energy described by Oldenburg (*C. A.* 23, 562), which may account for certain asymmetry of spectral lines noted when inert gases are present in the light-emitting vapor. GEORGE GLOCKLER

Duplicity of D terms in sodium and potassium. A. FRACHMIN AND S. FRISCH. *Z. Physik* 53, 326-30(1929).—The K lines, $2^2P_{1/2} - 5^2D_{5/2}$ 5832 and $2^2P_{1/2} - 6^2D_{5/2}$ 5360, have a weak satellite on their short-wave-length side. These satellites come from the duplicity of the $2D$ terms. The order of the $2D$ terms is reversed. $\Delta 5^2D_{5/2} = 0.62 \text{ cm.}^{-1}$. $\Delta 6^2D_{5/2} = 0.24 \text{ cm.}^{-1}$. The Na line $2^2P_{1/2} - 4^2D_{5/2}$ 5888 appears single with the optical equipment used. $\Delta 4^2D_{5/2} = 0.1 \text{ cm.}^{-1}$. The results are discussed from the point of view of regular doublet theory. G. G.

Width of resonance lines and displacement to the red due to multiple scattering. W. ORTMANN AND P. PRINGSHEIM. *Z. Physik* 53, 367-70(1929).—If the form of the spectral lines is mainly detd. (in a given discharge) by Doppler effect and impact damping, it is shown that a line reversal can take place through multiple scattering and without true absorption. However, under these conditions there cannot take place unsymmetrical displacement toward the red of the energy removed from the center of gravity due to successive Compton effects. This last effect can, however, take place if classical damping of the radiation alone is operative. A certain discussion by Fests (*C. A.* 21, 3555) of some work by Stuart (*C. A.* 19, 2009) concerning extinction of Hg resonance is criticized. GEORGE GLOCKLER

Optical properties of turbid solutions of non-metallic particles and some details of the Pulfrich step photometer. URSULA MÜLLER. *Ann. Physik* [5], 1, 229-59(1929).—The application of the Pulfrich step photometer to the measurement of absorption and lateral radiation is discussed at some length. Beer's law is tested and

found to apply over a wide range although it does not hold for very strong initial solutions. It is found that the ratio of absorption to concn. increases with concn. Depolarization measurements and observations on lateral radiation as a function of concn. are given for solns. of *mastic* and *gamboge*. J. B. AUSTIN

Use of crystalline quartz for spectrographic work. JOSEPH W. ELLIS. Univ. Calif. *J. Optical Soc. Am.* 18, 82-8(1929).—The presence of certain minima in the absorption bands of org. compds. in the infra-red is shown to be caused by a polarization effect in the quartz end plates. This effect can be enhanced or annulled by the introduction of a plane parallel glass in certain positions in the optical path. It is pointed out that considerable error in the measuring of relative intensities in the ultra-violet may result from this effect. WALLACE R. BRODE

Structure of multiplet S—states in diatomic molecules. H. A. KRAMERS. *Z. Physik* 53, 422-38(1929).—The unusual sepn. of the rotation levels of the 3S normal state of O_2 found by Mulliken (*C. A.* 22, 4063) can be explained theoretically if the mutual effect of the electron magnets is taken into consideration. G. G.

Intensity of forbidden lines. A. RUBINOWICZ. *Z. Physik* 53, 267-73(1929); cf. *C. A.* 23, 1053.—Quantum mech. relations for intensity and polarization for all transitions in the one-electron problem in a force field of spherical symmetry. GEORGE GLOCKLER

Investigations in the light-quantum theory. TOKIO TAKEUCHI. *Z. Physik* 50, 697-700(1928).—The Schrödinger wave equation for the motion of an electron is applied to the calcn. of the n s of a medium in a gravitational field, of the no. of light particles per unit vol., to the deduction of Brewster's law, and to superdispersion. W. W.

Isotope effect in iodine monochloride bands in neighborhood of the convergence. G. E. GIBSON. *Z. Physik* 50, 692-6(1928).—New absorption bands are found for ICl which have the same convergence frequency within the limits of the error of extrapolation as those previously reported. This new series is assumed to originate in ICl_7 . The theory of the isotope effect for harmonic oscillators according to the older quantum theory is generalized to include anharmonic oscillations of high quantum no. and found to give the correct relative positions of the vibrational terms of the 2 isotopes. W. WEST

Series in the arsenic VI spectrum. P. PATTABHIRMIAH AND A. S. RAO. *Z. Physik* 53, 587-91(1929).—Systematic assignment and arrangement of lines into series. GEORGE GLOCKLER

Spectrum of doubly ionized krypton. D. P. ACHARYA. *Nature* 123, 244(1929).—The strong group of lines about the wave length 3250 belongs to Kr^{++} , although a no. of irregularities are revealed. Data, so far obtained, are listed. F. V. J., JR.

The spectrum of doubly ionized potassium, K III. T. L. DE BRUIN. *Verslag Akad. Wetenschappen Amsterdam* 37, 984-91(1929).—Starting from the spectra of the neutral Cl atom, Cl I and of the mono-ionized A atom, A II, and by the use of the regular and irregular doublet law, B. derives the principal energy levels of the doubly ionized K atom, K III. Some regularities are recorded in the seven-electron systems F I, Ne II, Cl I, A II and K III. Also in *Science* 69, 47-8(1929). G. CALINGAERT

Spectrum of doubly ionized bromine. SURESH CHANDRA DEB. *Nature* 123, 244(1929).—The method of locating spectra by the horizontal comparison method of Saha and Majumdar being followed, the spectrum lines of doubly ionized Br were located. FRANK V. JOHNSON, JR.

Further triplets of trebly ionized arsenic (As IV). K. R. RAO. *Nature* 123, 244(1929).—Two more triplets were found due to As IV. FRANK V. JOHNSON, JR.

The theory of light scattering in liquids. C. V. RAMAN. *Phil. Mag.* [7], 7, 160-1 (1929); cf. *C. A.* 22, 2311.—A reply to the criticism of Rocard (cf. *C. A.* 22, 4065) and a defense of the priority claims of Raman and co-workers. L. H. REYERSON

The intensity of the scattered light from an unpolarized beam. W. S. STILES. *Phil. Mag.* [7], 7, 204-5(1929).—S. points out that Rayleigh inadvertently omitted a factor of $1/2$ in the expression for the intensity of scattered light from an unpolarized beam. The expression should be

$$\frac{A^2 (D' - D)^2}{8 D^2} (1 + \cos^2 \theta) \frac{\pi T^2 r^2}{\lambda^4 r^2}$$

where A^2 is the intensity in the primary beam and n the no. of particles in the given vol. element. The other terms have their usual significance. Rayleigh himself does not use the expression in later work; so the error is not propagated. The uncorrected result, however, has been copied in several standard works such as Wood's *Physical Optics*. L. H. REYERSON

Theory of the diffusion of light by a substance placed in an electric or a magnetic field. YVES ROCARD. *Ann. phys.* [10], 10, 472-88(1928).—Mathematical. Optical anisotropy is necessary, without which orientation effects disappear. Changes in intensity and polarization called for by theory are very small for exptl. observation at ordinary temps., but valuable results may be expected from work at low temps. L. A. S.

Reflecting power of beryllium, chromium and several other metals. W. W. COBLENTZ AND R. STAIR. *Bur. Standards J. Research* 2, 343-54(1929).—Data are presented on the ultra-violet reflecting power of various metals—Be, Cr, Co, Ni, Ag, speculum, stellite and stainless steel. For Cr and Be the observations extend into the infra-red. The observations show that contrary to the general experience with other metals, Be has a high reflectivity at 250 m. in the ultra-violet, followed by an appreciably lower reflectivity with a min. at about 400 m μ in the visible spectrum. Cr has a higher reflectivity than Ni in the ultra-violet and is, therefore, the more efficient as a reflector of ultra-violet radiation. The reflectivity of Cr is conspicuous for its relatively high max. (70%) at 425 m. followed by a wide, flat min., which extends from about 600 m. in the orange to wave lengths beyond 2000 m. in the infra-red.

G. CALINGAERT

The change in cathode-ray spectrum of nitrogen on cooling with liquid air. JONAS TAN AARS. *Ann. Physik* [5], 1, 216-28(1929).—It is shown that the distribution of intensity of the lines in the spectrum of N is not dependent on the gas pressure and the velocity of the cathode rays but is a function of the temp. alone. It is hoped that this method for detg. the temp. may prove of value in investigating the northern lights.

J. B. AUSTIN

Beryllium spectrum in the region λ 3367 1964. S. N. BOSE AND S. K. MUKHERJEE. *Phil. Mag.* [7], 7, 197-200(1929).—B and M obtained the arc spectrum of Be under different conditions of excitation. The following lines, λ 2351, 2175, 2126, 2056 and 2033, which are given as singlets by Millikan and Bowen, appear clearly as doublet but are probably triplets. A band spectrum was found with bands degraded to the red but the fine structure was not measured.

L. H. REYERSON

The infra-red emission spectra of the Bunsen and allied flames. C. R. BAILEY AND KUN-HOU LIH. *Univ. Coll., London. Trans. Faraday Soc.* 25, 29-32(1929). A sensitive thermopile-galvanometer combination in conjunction with a rock salt prism spectrometer was used to observe the infra-red spectra of the Bunsen flame and of the Meker burner in the region from 1 to 7 μ . The max. recorded are tabulated and for comparison are given those already detd. for CO, H and CH₄. The shifts which occur for the max. are attributed to the differences in temp. of the burner, the H₂O bands becoming of shorter wave length with increasing temp., and the CO bands becoming longer with increasing temp. Further, the intensity ratio of the bands at 2.8 and 4.5 μ was observed to vary greatly from flame to flame. C. C. K.

The infra-red emission spectra of the separated cones in the methane and Bunsen flames. C. R. BAILEY AND KUN-HOU LIH. *Univ. Coll., London. Trans. Faraday Soc.* 25, 32-6(1929).—The exptl. procedure described in the preceding abstr. was used to record the emission of the inner and outer cones of the CH₄ and Bunsen (total gas) flames from 0.5 to 8 μ . The max. observed are tabulated and the intensity ratios of the bands at 4.46 and 2.85 μ are given. From these data it is seen that radiation from the newly formed H₂O mole is much more intense in the inner than in the outer cone. No emission was observed from the newly formed CO mole in the inner cone. In the CH₄ spectra an emission band at 3.35 μ is attributed to thermal emission from the heated CH₄. C. C. K.

The series of the arc spectrum of tin. ADOLFO T. WILLIAMS AND FLORENTO CHACOLA. *Univ. of La Plata. J. phys. radium* VI 9, 377-85(1929).—A revision is made of the classification of the arc spectrum of Sn. With the aid of series formulas of the Hicks type it has been possible to establish the identity of hitherto unidentified terms and to find several new ones. Further, deep terms have been detected of which it is not possible at present to give the exact identification. The term structure is graphically shown by a Grottrian diagram and is seen to be in harmony with the requirements of Hund's theory. A list of all the classified lines from 5231 A. U. to 1756 A. U. is given. C. C. K.

The absorption spectra of the vapors of tin, silver and manganese from 5500 A. U. to 2140 A. U. R. G. LOYALTE AND A. T. WILLIAMS. *Univ. of La Plata. Pap. Z.* 20, 66-75(1929).—The absorption spectra of the vapors of Sn, Mn and Ag were photographed in the region 5500 A. U. to 2140 A. U., the observations being made through a range of temps. from 1200° to 2200°. The source of continuous light was a H discharge tube of special design. The absorption lines observed for Sn represent com-

binations of various higher terms with the 3 lowest terms 1S , 1D and 3P of Sn I; for Mn the lines observed represent combinations of higher terms with the basic term 4S of Mn I. For Ag, however, lines characteristic of Ag^+ were obtained in addn. to the doublet $1^3S_0 - 2^3P_{1/2}$ of Ag I.

C. C. KIESS

Stark effect of helium 2P-6D line by quantum mechanics. YOSHIO FUJIOKA. *Sci. Papers Inst. Phys.-Chem. Research* (Tokyo) 10, 99-106(1929).—(In English.) The components and their intensities in the Stark effect for the He line $2P - 6D$ at 4144 Å. U. are calcd. on the basis of the quantum mechanics. The results are presented in tabular form and are illustrated by a graph which is compared with a photograph of the line obtained by the Lo Surdo method with a max. field of 9.8×10^4 v./cm.

C. C. KIESS

The absorption spectrum of carbon disulfide in the near ultra-violet. EARL D. WILSON. *Ohio State Univ. Astrophys. J.* 69, 34-42(1929).—White light from an under-water spark was passed through CS_2 under a variety of conditions, such as different lengths of absorbing column, and different vapor pressures, to det. those most favorable for bringing out the absorption bands. From spectrograms obtained with a quartz spectrograph about 650 wave lengths were measured between the limits 3800 Å. U. and 2900 Å. U. in the ultra-violet. The intensities of the lines were estd. from curves obtained with a microphotometer. Some of the lines appear to be related through conf. wave-no. differences and these have been grouped into tentative series.

C. C. KIESS

The spectrum of the aurora borealis. JOSEPH KAPLAN. *Univ. of Calif. Science* 69, 296-7(1929).—Two weak lines of wave lengths 5176 Å. U. and 5149 Å. U. in the auroral spectrum are accounted for on the assumption that N atoms in the 3D state transfer their energy of 2.38 v. to N mols. in the metastable states A_0 and A_1 through collisions of the second kind. The mols. now raised to the B_0 and B_1 states, radiate the bands with heads at wave lengths practically coincident with those given above.

C. C. KIESS

Stark effect in neon. J. S. FOSTER AND W. ROWLES. *Phys. Rev.* 29, 925 (1927).—The observed symmetrical Stark patterns for the line groups of higher order were remarkably H-like in character. Each of the lines $2p_i - 4f$ and $2p_j - 5f$ appears as a doublet, and the 2 members of the doublet present nearly identical Stark effects.

B. C. A.

Relation intensities of the Stark effect components of $H\alpha$, $H\beta$ and $H\gamma$. H. MARK AND R. WIERL. *Z. Physik* 53, 526-41(1929).—See C. A. 23, 767.

G. G.

The spark potential of air in narrow channels. A. GYEMANT. *Siemens Schuckert A. G., Berlin. Naturwissenschaften* 17, 135(1929).—For electrode distances of 0.1 to 1 mm. the spark potential of air is up to 20% above the normal value if detd. in the thin air channels which occur in insulating masses with a ratio of channel diam. to channel length of at least 1:10. No retardation effect is believed to cause this; the values are well reproducible; irradiation with ultra-violet light does not influence it; the values are equally high during rapid repetitions. The explanation given by G. is energy absorption by the walls of the channel from deviating electrons.

B. J. C. VAN DER HOEVEN

The arc and spark spectra of the halogens. LEON BLOCH and EUGÈNE BLOCH. *Nature* 122, 171(1928).—The authors have given a complete sepn. of the arc and spark spectra, as well as a division of the latter into spectra of the first and second orders, for Cl, Br and I.

FRANK V. JOHNSON, JR.

Absorption of ultra-violet light by the glucosans. I. KWIECINSKI AND L. MARCILEWSKI. *Bull. intern. acad. Polonaise* 1928A, 263-9.—Since the glucosans are anhyd. glucoses possessing 3 rings, they could be expected to show selective absorption. β -Glucosan, m. 167°, $[\alpha]_D^{18} = -66.0^\circ$, showed an absorption band about $\lambda = 2700$. Recrystn. raised the m. p. and lessened absorption markedly and a second recrystn. brought the m. p. to 179.5° and eliminated all traces of an absorption band. Distinct and strong absorption by the mother liquors proved the original absorption to have been due to impurities which were removable by recrystn. α -Glucosan (unknown purity), m. 108-9°, $[\alpha]_D^{21} = +69.40^\circ$, gave a distinct absorption band at $\lambda = 2800$. This band may appertain to the pure α -glucosan but if due to impurities, it follows that they are not the same as those which produced absorption in the former case.

C. H. PEAR

The absorption of ultra-violet light by the inversion products of sucrose. I. KWIECINSKI AND L. MARCILEWSKI. *Bull. intern. acad. Polonaise* 1928A, 257-61. —Though neither reducing nor non-reducing carbohydrates show selective ab-

sorption of ultra-violet light when very pure, impurities generally present cause a band in the region $\lambda = 2700$ – 2800 . Fructose is an exception in that it has not been susceptible of sufficient purification to eliminate this band completely. Since *d*-glucose shows none and *d*-fructose only a very faint absorption band, the spectrum resulting from the inversion of very pure cane sugar should be predictable; but it is not, because glucose or fructose or both undergo changes which result in strong selective absorption in the vicinity of $\lambda = 2800$. The identity of the compd. causing the observed absorption band is not known but it can hardly be methylglyoxal since this has an absorption differing in position and structure from that observed. C. H. PEET

Absorption of ultra-violet light by arabinose, maltose, sucrose and raffinose and by mannitol and dulcitol. L. KWIECINSKI AND L. MARCHELEWSKI. *Bull. intern. acad. Polonaise* 1928A, 271–82.—*l*-Arabinose (?)—written "d" on fig. 1—impure, m. $146-7^\circ$, $[\alpha]_D^{17} = 88.85^\circ$, showed a band at $\lambda = 2800$; recrystd. thrice, m. 155° , $[\alpha]_D^{17} = 103.54^\circ$, showed no selective absorption. Maltose (com. "Maltose pur cryst.") E. de Haën, $[\alpha]_D^{20} = +136.36^\circ$, gave an absorption band at $\lambda = 2800$ which disappeared after 3 recrystns. The recrystallized product gave $[\alpha]_D^{20} = 136.84^\circ$. Sucrose—four samples from various sources but all of high purity—varied in transparency to transmitted ultra-violet light, but showed no selective absorption. Raffinose (com. E. Merck) recrystd. thrice from 50% alc., m. 81° , $[\alpha]_D^{15} = +105.4^\circ$, showed no absorption band. Mannitol (com. E. Merck) recrystd. thrice from 66% alc., m. 166° , gave no absorption. Dulcitol (com.) recrystd. thrice from 66% alc., m. 186° , showed no band. Previously reported absorption bands for reducing carbohydrates by other observers must have been due to insufficient purification. C. H. PEET

Absorption of calcium fluorides. STEPH. VAN DER LINGEN. *Z. Physik* 53, 581–6(1929).—The absorption of South African fluorite is compared with that of fluorite from England. Hilger's Infra-red spectrometer Type D 42 was used. G. G.

Absorption measurements in the principle series of cesium. F. WAIBEL. *Z. Physik* 53, 459–82(1929).—The broadening due to the vapor pressure of the emitting vapor of Cs is measured for pressure from 10 to 32 mins. The intensities in the principal series of Cs are detd. (5th to 14th series member) by making absorption measurements, a photographic photometric method being used. A large asymmetry is noted for the absorption of the lower series lines. The asymmetry disappears for higher no., beginning with line No. 10. The broadening is found approx. proportional to the square root of the vapor density. The half width decreases with increasing series no. but becomes const. for the higher series nos. The half width of the strong components is markedly greater than for the weaker ones. The intensity ratio of the components of the 5th and 6th doublet is detd. Total absorption, no. of resonators per atom and transition probabilities are measured absolutely from the 5th to the 14th series no. A microphotometer is described. GEORGE GLOCKLER

The absorption of ultra-violet radiation in ozone. A. LAUCHLI. *Z. Physik* 53, 92–4(1929).—The absorption of O_3 is detd. with the spectroscopic refinements possible today. The empirical relation of the absorption coeff. (α) as a function of wave length is found to be: $\log \alpha = 16.74 - 0.0536\lambda$ (λ in $m\mu$). Fabry and Buisson had found: $\log \alpha = 17.58 - 0.0564\lambda$ (C. A. 7, 2153). GEORGE GLOCKLER

Infra-red radiations of active nitrogen. P. K. KICHLU AND D. P. ACHARYA. *Proc. Roy. Soc. (London)* A123, 168–71(1929).—See C. A. 22, 3355. E. C. M.

Comparison of the absorption of water and quartz in the extreme ultra-violet. K. TSUKAMOTO. *Rev. d'optique* 7, 89–108(1928); *Science Abstracts* 31A, 613.—The detns. were made by the method of photographic photometry. A series of photographs, using const. exposure, were obtained on one plate using a source of const. intensity and weakened in successively known proportions. The effects produced by the water and quartz were compared with these standard spectra and their absorption coeffs. then compared. To obtain a source of const. intensity in the desired region 1830–2300 Å. U. a condensed spark discharge between metallic electrodes was used and a metallic grating used to reduce the intensity of the illumination. For water and quartz the absorption found for various wave lengths between 2200 and 1829 Å. U. is tabulated. For water the values are smaller than those found by Kreusler, while for quartz the values exceed Pfleger's. The wave-length-absorption curves for these 2 substances intersect for $\lambda = 1999$ Å. U. Water is very transparent for $\lambda > 1950$ Å. U. but below this value it decreases rapidly. The absorption of quartz increases slowly from 1890 to 2300 Å. U. H. L. D.

The transformation spectrum of the ruby. E. L. NICHOLS AND H. L. HOWES. *Proc. Natl. Acad. Sci.* 15, 139–45(1929).—A summary of the characteristics of the

luminescence of the ruby under cathodo- and under photo-excitation is given. A synthetic ruby with fairly smooth faces was mounted on an alundum splinter and heated to over 1000°. At this temp. the spectrum was continuous but no narrow emission bands were noticed. However, during repeated heatings and coolings of the crystal 21 narrow emission bands, called the transformation spectrum, were counted between 0.780 μ and 0.426 μ . The temp. range was studied under a prepd. black-body radiation by means of an optical pyrometer and found to be approx. 600° to 775° in the red. This corresponds to profound changes in the absorption of light in the ruby. No obvious relationship was found between the transformation spectrum and the bands of fluorescence and absorption mapped by DuBois and Elias, but when wave nos. ($1/\mu \times 10^3$) were taken instead of wave lengths both fell into sets having a common frequency interval of 36.7.

C. H. BADGER

The Raman spectra of scattered radiation. W. W. COBLENTZ. *Phil. Mag.* [7], 7, 203-4(1929).—C. gives a table comparing his measured values of the infra-red absorption bands for benzene and calcite with those calcd. by Raman and Wood from the frequency difference between the exciting line and the Raman line. The agreement is good.

L. H. REYERSON

Raman effect with hydrochloric acid gas: the "missing line." R. W. WOOD. *Nature* 123, 279(1929).—A Cooper-Hewitt lamp about 5 ft. long was placed parallel to and in contact with a tube contg. HCl gas at atm. pressure. A cylindrical reflector of highly polished Al was in contact with, and completely surrounded, the tubes. With this arrangement the temp. rose to about 100. With an exposure of 24 hrs. a sharp, distinct line was obtained at 4581 A. U. On the assumption that this modified line is excited by the Hg line 4046, the frequency difference corresponds to a line in the infra-red at 3.47 μ , almost exactly at the center of the vibration-rotation band. This identifies the line as the so-called "missing line" corresponding to a vibration transition unaccompanied by a change of rotation. Six lines have also been obtained immediately on the long-wave-length side of 4358.

W. W. STIFLER

Raman lines from hydrochloric acid gas. R. W. WOOD. *Nature* 123, 166(1929).—By using a long end-on tube excited by a parallel Cooper-Hewitt Hg arc with Al reflectors, the modified lines of gaseous HCl were obtained at atm. pressure, corresponding to the vibration-rotation absorption band at 3.6 μ .

W. W. STIFLER

Apparently anomalous Raman effect in water. JOSEPH W. ELLIS. *Nature* 123, 205-6(1929).—The Raman scattering by H₂O mols. yields only one modified frequency corresponding to the infra-red band at 2.90 μ . This seems anomalous since (1) the modified line is really a broad band in contrast to the sharp Raman lines produced by org. liquids; and (2) there is no infra-red band corresponding exactly with the center of the observed scattered band, the nearest one being 3.0 μ . E. explains these results by pointing out that the 3.0 μ band is probably double, being made up of an overtone of the 6.1 μ band and a new fundamental with wave length 2.9 μ . This makes the behavior of H₂O analogous to that of NH₃ in aq. solu. and various org. liquids. The comparatively great breadth of the scattered line is shown to be consistent with that of the infra-red bands of H₂O.

W. W. STIFLER

The width of the lines in the Raman spectrum of benzene. WALTER GERLACH. *Ann. Physik* [5], 1, 301-8(1929).—The Raman lines are not sharp but are diffuse. On account of the great intensity difference between the middle and the edge of the line it is not possible to det. the width directly; so round-about methods must be used. In regard to the structure of the infra-red bands of benzene it is indicated that they are not composed of unresolved vibrations of the same sort with a small frequency difference but are made by a principal frequency raised or lowered by a no. of secondary long-wave vibrations. Measurements of the widening of the Raman lines gives no data on the frequency differences of these long-wave vibrations.

J. B. AUSTIN

Intensity and temperature dependence of quartz-scattered light. G. LANDSBERG AND M. LEONTOVICH. *Z. Physik* 53, 439-48(1929).—The intensity of the most prominent red satellites of light scattered by quartz reaches 40% of the intensity of the principal line. With increasing temp. the intensity of this red satellite remains practically const., the intensity of the principal line increases proportionally to $\sqrt{\text{temp.}}$ and the intensity of the violet satellite increases still faster.

G. G.

Raman effect with quartz. M. CZERNY. *Z. Physik* 53, 317-25(1929).—See C. A. 23, 1812.

GEORGE GLOCKLER

The production of new radiations by light scattering. I. C. V. RAMAN AND K. S. KRISHNAM. *Proc. Roy. Soc. (London)* A122, 23-35(1929); cf. C. A. 22, 2707; 23, 37. The modified scattering exerted in C₂H₄, C₂H₂-CH₃, and CCl₄ by the 4358 group

of Hg lines is reported in detail. Satisfactory agreement is considered to exist between the infra-red frequencies calcd. from the modified frequencies and those obtained by direct measurement in the infra-red; moreover, the Raman spectra of $C_6H_6 \cdot CH_2$ and CCl_4 contain lines corresponding to hitherto unknown infra-red bands extending as far as 46μ in a region not readily accessible by direct measurement. Anti-Stokes lines are found in all 3 spectra, most conspicuously in that of CCl_4 . The unmodified lines are accompanied by a nebulosity, particularly strong in benzene, the origin of which is suggested to lie in a Raman effect between the pure rotational frequencies of the mol. and the incident frequency. All the unmodified lines are polarized to practically the same extent; the modified lines corresponding to a given frequency shift are polarized to the same extent, but differ in polarization from the unmodified, the modified lines corresponding to different frequency shifts are differently polarized, the anti-Stokes lines are polarized to the same degree as their long-wave companions, the continuous modified spectrum in Am alc. is strongly polarized. A tentative explanation of these effects is given. Preliminary qual. observations indicate that the intensity of modified scattering changes with wave length of the exciting line even more rapidly than according to an inverse 4th power law. W. WEST

Method for the measurement of weakly elliptically polarized ultra-violet light. G. SZIVESSY AND CL. MUNSTER. *Z. Physik* 53, 13-51(1929).—General discussion of elliptical polarization and description of a spectropolarimeter especially suited for the measurements in question. GEORGE GLOCKLER

Relation between luminosity and concentration in luminescent solid solutions. J. EWLERS. Univ. Leeds. *Proc. Leeds Phil. Lit. Soc., Sci. Sect.* 1, 341-5(1929).—A soln. of Bi in CaO being used the curve obtained from the intensity of luminescence and concn. of Bi in CaO, shows 2 maxima. This would require a formula of $I = Ae^{-n_1r} + Be^{-n_2r}$ to represent the luminescent intensity, where A , B , n_1 and n_2 are consts. and r is the concn. of Bi. The exptl. evidence supports the view that a luminescent solid soln. consists of a no. of active atoms distributed at random in a transparent lattice and that the luminescent center consists of 1 atom of active metal associated with a definite no. of lattice points. WALLACE R. BRODE

Influence of the walls on gas phosphorescence. MARIA MAJEWSKA AND W. BERNHARDT. *Z. Physik* 48, 137-40(1928); *Science Abstracts* 31A, 586-7. As a supplement to the work of Herzberg (*C. A.* 22, 1911) on the phosphorescence of N and O and the influence of the walls thereon, a few of the authors' previous results are given again. It is not sufficient to choose the pressure and excitation conditions, the tube must be "prepd." in a definite way. Conclusion: The walls are covered with some unknown gas (possibly N_2O_4) which catalytically decomposes the gas in the tube. H. L. D.

Theory of sensitized fluorescence. A. CARRELLI. *Z. Physik* 53, 210-6(1929). It has been known through the work of Cario and Franck (*C. A.* 18, 2288) and Bontler and Josephi (*C. A.* 21, 3021) that the most probable transfer of energy during a collision of the second kind is that transfer in which the exciting atoms and the to be excited system have nearly the same energy. C. derives this same result theoretically from considerations of Schroedinger wave-mechanics. GEORGE GLOCKLER

Photochemical studies. I. J. HOUERN AND W. FISCHER. *Arch. bot. series Land. Forstw.* 15, 601-8(1928). Photochem. decompn. of water into H and H_2O_2 or synthesis of CH_2O from CO_2 and water, could not be detected. CH_2O in ultra-violet light affords strongly reducing substances (pentoses); MeOH and KNO_3 produce formhydroxamic acid, which is rapidly decomposed by CH_2O in light. Neither purine substances nor α -amino acids were detected. Instead of alkaloid which Baly claims to have isolated, alkylamines giving the usual alkaloid reactions were obtained. B. C. A.

Refraction of beams of molecules. I. I. RABT. Univ. of Hamburg. *Zeit.* 123, 163-4(1929).—A modification of the Gerlach and Stern expt. is discussed for the case of a beam of alkali atoms shot into a uniform magnetic field at right angles to the lines of force. Such an arrangement is analogous to the case of refraction of light on passing from one homogeneous medium to another, and avoids the difficulties attendant upon measuring the gradient of an inhomogeneous magnetic field. The equation for the total deviation is deduced and it is shown that a measurable deflection should be obtainable. Similar considerations apply to a beam of atoms projected through the elec. field of a parallel-plate condenser. The complete discussion, with exptl. details is to be published in the *Zeit. f. Physik*. W. W. STIEGLER

Photochemical union of hydrogen and chlorine. A. J. ALLMAND AND EDWARD BUNNAY. King's Coll., London. *Nature* 123, 184(1929).—The photochem. union

of H_2 and Cl_2 was investigated for moist electrolytic gas, with special attention to the effects of intensity and wave length, monochromatic light from a quartz Hg lamp being used. The results for variations in intensity confirm the previous work of Mrs. M. C. Chapman, Kornfeld and Steiner, and Marshall. For the wave lengths 260, 313, 365, 405, 436 and 546μ the corresponding quantum efficiencies were found to be 0.10, 0.49, 0.53, 1.00, 0.67 and 0.22, resp. The sensitivity of the gas corresponded to a yield of approx. 200,000 HCl mols. per quantum of absorbed light. Expts. at 19.7° and 25° showed a small but definite increase in the relative temp. coeffs. of quantum efficiency for wave lengths between 313 and 436μ . When 2 monochromatic beams were allowed to act simultaneously, the results were additive. W. W. S.

Dissociation of hydrogen by collisions of the second kind. JOSEPH KAPLAN. Univ. of Calif. *Nature* 123, 162-3(1929).—A new explanation is offered for the Cario and Franck expt., based on the new 1^3S level for the H_2 mol. recently computed by Heitler and London. It is assumed that a collision between an excited Hg atom and a normal H_2 mol. results in the excitation of the H_2 mol. from the 1^1S to this new 1^3S level. The potential-energy curve in this level has no min. Hence this state is unstable and dissoen. immediately results. W. W. STIFLER

Zinc oxide and chlorophyll as optical sensitizers. JAKOB BÖHL. Tech. Hochschule, Zürich. *Helv. Chim. Acta* 12, 121-53(1929).—The source of radiation for these expts. was an Osram-Nitra lamp of 3000 c. p. Prussian blue in the presence of Zn oxide in water is converted into Berlin white. According to Baur's theory the photosensitizer acts as an oxidizing and reducing agent just as the 2 electrodes of an electrolytic cell, giving rise to oxidation and reduction products. With an anodic depolarizer such as grape sugar, B. found that there was a slight increase in the amt. of Prussian blue reduced. (Tables are given.) The photolysis of $CuSO_4$ in binary and ternary solns. is very interesting; in the first case CuO is formed; while in the presence of an anodic depolarizer the cupric ion is reduced first to cuprous and then to metallic Cu. (Exptl. details are fully explained.) Moist ZnO and a mixt. of H_2 and O_2 when illuminated result in the formation of H_2O and H_2O_2 . Some 25 dyes in MeOH soln. are reduced by illumination in the presence of chlorophyll. Oil of turpentine acts as an anodic depolarizer in such cases. Piperidine and phenylhydrazine were used in like manner. A considerable bibliography is given. All of the observed phenomena are related by B. to Baur's theory. WILLIAM E. VAUGHAN

The action of ultra-violet rays on the formation of sugars and of aldehydes from solutions of bicarbonates and carbon dioxide in the presence of reducing and colloidal catalysts. GIUSEPPE MEZZADROLI. *Rev. ind. agr. Tucumán* 19, Nos. 5-6, 154-9 (1928).—A Hg vapor lamp, "Original Hanau," was used, with an a. c. of 3.8 amp., 220 v., emitting 2000-6000 A. U. Much O_2 was formed on the surface of the liquid, oxidizing org. substances, and absorbing the shorter waves; hence antioxygen substances were added to the soln. exposed. An increase in reducing power of 30-50% is obtained in solns. of $Ca(HCO_3)_2$, $KHCO_3$ and of CO_2 in distd. water. Better yields are obtained when metallic Mg or Zn, $Cu(OH)_2$, $Al(OH)_3$, Ca bicarbonate, $CaCO_3$, or lime is added. The best results were obtained from $Ca(HCO_3)_2$ in the presence of very finely powd. metallic Mg. S. L. B. ETHERTON

Influence of quartz lamp irradiation on adsorptive power of certain adsorbents. E. V. ALEKSEVSKII. *J. Russ. Phys.-Chem. Soc.* 60, 1173-8(1928).—The irradiation of active charcoal and of Patrick's silica gel, using a quartz lamp, slightly enhances the adsorptive power of these substances. B. C. A.

Discoloration of thin silver iodide films by light. ERNST JENCKEL. Univ. Göttingen. *Z. anorg. allgem. Chem.* 179, 80-96(1929).—Illumination changes the interference colors of very thin films of AgI formed by the action of I_2 vapor on metallic Ag. The color changes are attributed to formation of Ag in the film. In a table the colors are indicated which illumination (up to 6 hrs. daylight) will cause in AgI films of thickness 0 to 834μ , and the color changes subsequently brought about if the films are again exposed to I vapor. From an equation of Mie (C. A. 2, 2485) are calcd. for particle sizes (Ag) of 20, 40, 60 and 80μ , resp., the colors of the scattered light; they are successively blue, green, yellow and red in agreement with the results found (brown taking the place of blue, which is typical for Ag). The appearance of the colors and their changes are discussed at length. B. J. C. VAN DER HOEVEN

Active nitrogen. II. Influence of surface on the afterglows in nitrogen and oxygen. III. Mutual effect of nitrogen and oxygen on their respective afterglows. BENARD LEWIS. *J. Am. Chem. Soc.* 51, 654-65, 665-74(1929).—Expts. have shown that the condition of the surface of the contg. vessel is a detg. factor which governs the visibility of the afterglow in N and O, the N afterglow being made observable

only after the surface of the vessel has been effectively a layer of gas. Studies were made with different mixts. a sequence of changes in the character of the afterglow is reduced in the same mixt.

by the absorption of N and O at various pre- recorded as the pressure

RANK V. JOHNSON, JR.

Active nitrogen. VI. The formation of iron nitride in the iron-nitrogen arc. ERIC J. B. WILLY. *J. Chem. Soc.* 1928, 2840-4; cf. *C. A.* 22, 3839.—When an arc is burned between Fe poles in an atm. of N, Fe_3N_2 is formed in the metal-vapor zone. The amt. of Fe present as the nitride in the vapor decreases from 12% of the total Fe in the inner zone to 6% in the outer zone. Examn. of the arc with a spectrometer failed to reveal the bands characteristic of the N afterglow spectrum. The results are interpreted as showing either that the active N is here non-luminous, or that, under the more intense current of the arc as compared with the condenser discharge, another and chemically more active modification of N is produced (cf. Lowry, *C. A.* 6, 2895).

H. F. JOHNSTONE

Photovoltaic cells with silver-silver bromide electrodes. I. W. VANSELOW AND S. K. SHEPPARD. *J. Phys. Chem.* 33, 331-53(1929).—Photovoltaic cells consisting of Ag-AgBr electrodes in soln. of KBr have been studied. The p. d.-time curve obtained is the resultant of 2 effects, viz., an initial neg. effect on which is superimposed a pos. effect. A hypothesis was developed explaining these in terms of the liberation of electrons and Br atoms from bromide ions on absorption of light. In agreement with this it is shown that the pos. effect can be suppressed, the neg. effect made more pronounced, by addn. of Br acceptors. The pos. effect is shown to be similar to that produced by allowing Br to diffuse through the AgBr layer to the Ag.

Investigations of the chemical action of electric discharge and spark in gases under low pressure. HENRI LEPEVRE AND PIERRE MONTAGNE. *Bull. soc. encour. ind. nat.* 1928, 917-23.—L. and M. accept the theory that in the elec. arc chem. actions are due to intense ionization of gases and to electron movements in the vicinity of the electrodes. They then proceed to det. what laws are obeyed when gas pressure or certain characteristics of the elec. circuit are modified. There is a decided similarity between the action of spark or discharge and that of heat. A digression is also made to study the particular case of activation of N by elec. discharge. CO_2 is chosen as gas for the investigation. Under the exptl. conditions disson. of CO_2 proceeds according to the equation $2CO_2 = 2CO + O_2 - 136.4 \text{ cal.}$, CO remaining unchanged when traversed by discharge or spark. The app. used is a glass tube with 2 electrodes connected to vacuum or to CO_2 generator; during the passage of sparks it is insulated from the rest of the app. Results from the action of condensed spark and continuous current are in perfect accord with prediction from study of thermal decomn. of CO_2 . Results from special investigation of N show that activated N acts as catalyzer, under its influence CO , unstable at ordinary temp., is transformed into CO_2 and C.

M. McMAHON

Is hydrogen peroxide formed in electrolytic gas by α -rays? BARNARD M. MILES. Univ. Minnesota. *J. Phys. Chem.* 33, 381-3(1929).—In previous work on the combination of H_2 and O_2 (electrolytic gas) at room temp. by the use of α -rays from Pu (*C. A.* 8, 3394), a static method had shown an excess of H_2 over that required for H_2O formation; this was attributed to the formation of H_2O_2 , as O_2 cannot exist in the presence of Hg. The present expts. were carried out in such a way that both O_2 and H_2O_2 could be detd. in the collected reaction products should they be present. O_2 , if present at all, was shown to be so in amts. less than the vapor pressure of O_2 at liquid-air temp. The amt. of H_2O_2 present was less than 1.5×10^{-7} equiv. The error in the previous work was probably due to the presence of Hg, which combined with the O_2 , leaving an excess of H_2 .

Comparison photometer for use with ultra-violet rays. I. G. FARBERIND. A.-G. Brit. 296,198, Sept. 8, 1927. There is exposed to irradiation a soln. of a phototropic coloring substance (such as one of the leucocyanides, carbinols or sulfurous compds. of basic coloring matters) to which is added a small proportion of a substance counter-acting the photochem. color change and the degree of color change produced is detd. by comparison with a scale of standard solns.

Röntgen-ray screens. C. HAIDER. Brit. 297,037, Sept. 12, 1927. Two glass plates sealed at their edges and with a rarified space between them, or two "cellon" plates compressed together, enclose between them a substance which phosphoresces under the action of Röntgen-rays, such as Zn sulfide, calcspar, siliceous calamine, magnesite or dolomite. Mention is also made of screens comprising Ba. cyanoplatinite and artificial willemite.

Photochemical reactions. I. G. FARBERIND. A.-G. Fr. 647,730, Nov. 14, 1927. Photochem. reactions are produced in gases or vapors by resonance radiations, the max. intensity of irradiation in the reaction chamber being obtained by arranging the app. so that the metallic vapor which emits the radiations surrounds the gases on all sides or the reaction chamber surrounds the source of the radiations. A relatively high intensity of the narrow resonance ray is obtained by the addn. of indifferent gases such as He, or the use of high-frequency vibrations. Examples are given of the production of aldehydes from mixts. of CO and H.

4—ELECTROCHEMISTRY

COLIN G. FINK

Recent developments in electric furnaces. D. F. CAMPBELL. *Institute of Metals* (advance paper) 482, 20 pp., *Engineering* 127, 439-42(1929); cf. *C. A.* 23, 1353.—The Ajax-Wyatt furnace for brass melting is built in 600, 1200 and 2240 lb. sizes. The largest size is used as a metal mixer when scrap of varying composition is charged, a large amount of metal being kept in the furnace at all times. Usually the bulk of the metal is poured, in which case the smaller units are preferred. The 1200 lb. furnace is 10% more efficient, but if many small castings are to be made the time out for pouring makes it more economical to use the 600 lb. unit. A large number of Ajax-Northrup furnaces, 800-2000 lbs. capacity, have been installed for Ni and Fe alloys. In these furnaces a new method of lining has reduced the lining cost to 24-72¢ per ton. This method consists of pouring a suitable lining material between the furnace coil and a metal liner. The heat induced in the metal frits the mixture into a crucible of the required composition. Elec. heat-treating furnaces may be advantageously substituted for coal, oil, or gas-fired furnaces in some cases. When close control at relatively low temps. (500-800°) is required, the elec. furnace will be preferred. Electricity lends itself to more efficient design than does gas; in one case with elec. energy at 1.4¢ per kw. hr. and gas at 66¢ per 1000 cu. ft. the loss of heat from a well-designed elec. furnace costs 42¢ per hr., as against \$1.58 per hr. as the heat-loss cost for an equivalent gas furnace. The first cost of elec. furnaces is high, especially when they are designed for high efficiency. This cost must be justified by the high unit cost of heat; high efficiency also reduces rating, which in turn lowers the max. demand charge. As an example of efficient design, a box-type furnace with a hearth area of 4 ft. 3 in. by 3 ft. 3 in. and a height of 3 ft. 6 in. is cited. It can be maintained at 800° by 10.5 kw., and requires 44 hrs. to cool from 700° to 260°. Elec. annealing furnaces for brass strip cost more than gas furnaces but give a light, even oxide film, reducing pickling costs and improving the surface. A short description of a completely electrified German brass works is given. This plant takes \$8,000,000 kw. hrs. per yr. The max. demand is 6260 kw., the power factor 0.929, and the load factor 62.1, so that a day rate of 0.6¢ and a night rate of 0.3¢ are earned, with power supplied by a fuel-burning station. B. M.

An electric heat-treating furnace. R. FR. RUSS. *Giesserei* 16, 61-2(1929).—A description of 3 elec. furnaces and their advantages over other types. J. B.

The electrochemical method of cadmium for rust prevention. S. WERNICK. *Metal*

Ind. (London) 34, 245-8(1929).—A brief discussion of Cd plating covers: the electrode efficiency ratio, compn. of solns. and effects of variations in content, effect of phys. conditions, such as temp. and c. d., addn. agents, throwing power of soln., properties of Cd deposit, reaction to chemicals, composite deposits and mech. properties. Electrode efficiency approaching unity may be secured with the following conditions: relatively high metal content (30 g./l. Cd), free CN to 100% without bad effect, and caustic alkali 15-30 g./l., c. d. 10-15 amp./sq. ft., and a moderate temp. Cd-Ni deposit is superior in protective capacity to Ni alone but inferior to that of Cd alone, a good Cd deposit having great adhesion. Addn. agents, in general, are undesirable for Cd plating. Two-soln. plating is often desirable. The first is a flash-cleaner soln. (low Cd-high caustic soln.) and the second the regular plating bath. W. H. B.

Methods of silver plating. F. C. MRSLE. *Metal Ind.* (N. Y.) 27, 128-30(1929). Recent improvements in Ag plating have been confined to solns. and control methods, analysis, attention to temp. and c. d. Distribution of current, agitation and filtration of soln. are discussed. CS_2 in very small quantities (1/500) is used as a brightener. KCN seems more desirable than NaCN, but the reason is unknown. W. H. B.

Applications of cadmium. N. F. BURGESS. *Elec. Rev.* (London) 102, 306-8 (1928); *Science Abstracts* 31B, 301. The use of Cd in batteries is first described, particularly with reference to alk. accumulators. One of the advantages over the ordinary lead-acid cell is that it may be completely discharged, or allowed to remain charged, though not in use, for any length of time without harmful results. On the other hand, the cost is about 3 times as much as for Pb-acid cells of the same amp. hr. capacity. In the manuf. of standard cells Hg-Cd alloys have an important application. If a Cd strip is immersed in the electrolyte of any cell and connected to one terminal of a low-reading voltmeter, the other terminal being connected to either the pos. or neg., a difference of potential can be recorded, and one can detect whether the pos. or neg. element is at fault in a weak cell. Cd is also used as a high-temp. resistor material. A Cd-vapor arc lamp has been devised, but probably one of the most important future applications of this metal lies in its addn. to Cu. H. I. D.

Theory of electrolytic precipitation of chromium from chromic acid solutions. ERICH MÖLLER AND PER EKWALL. *Z. Elektrochem.* 35, 84 (1929), cf. *C. A.* 20, 2995.

Reduction of Cr^{VI} to Cr^{III} takes place at a C cathode at potentials (against normal calomel electrode) up to 0.8 volt, while at Pt there is little or no reduction. In order to det. whether the absence of reduction was due to stratification, the region below 0.8 v. was investigated. The purest obtainable CrO_3 was treated with a small amount of $\text{Ba}(\text{OH})_2$, heated until the BaSO_4 pptd., and filtered through fritted glass. A rectangular cell, 2 by 3 by 2 cm., equipped with a glass cooling coil, was fitted with 2 identical new Pt electrodes, 1 by 2 cm., mounted parallel to each other at the smaller sides of the cell. A capillary siphon was brought in just under the cathode, with its opening touching the back side of the cathode. This back side, and the upper half of the front side, was covered with paraffin. The siphon led to another vessel, which contained 20% CrO_3 , and which in turn was connected to a normal calomel electrode by a KCl-filled siphon. The current through the cell was controlled to keep the cathode-calomel electrode potential const. during the run. After the expt. was concluded the cathode was removed, carefully washed and dried, and photographed at 50 diams. Runs were made with the pure 20% CrO_3 , with the same after making 0.001, 0.01, 0.05 and 0.1 normal with H_2SO_4 , and with 20% pure CrO_3 to which had been added sufficient H_2O_2 to reduce about 13% of the Cr^{VI} to the trivalent state. At potentials higher than -0.7 v. no change in the cathode surface could be seen in any case. As the voltage was decreased (by increasing the current) ppts. of various hues appeared, and finally metal was deposited. The appearance of cathodes from solns. containing sulfate ion was markedly different, in that metal was deposited with efficiencies of 100% whereas in the sulfate-free solns. only very small amounts were pptd. R. M.

Notes on the testing of electrodeposits on aluminum. G. B. BROOK AND GEORGE H. STORR. *Institute of Metals* (advance paper) 484, 9 pp.—An adhesion test for electrodeposits on Al consists of twisting a strip 8 × 0.5 in. around a 0.5 in. bar, which is held in the chuck of a lathe rotating at 20 r. p. m. One end of the strip is inserted into a slot in the bar, cut so that the angle of emergence is 60° and rounded to prevent fracture of the specimen; the other end is held firmly with pliers. Immersion of the sample in brackish water at half-tide level for three months was used as a corrosion test. Of 10 samples tested, five passed the adhesion test satisfactorily, 6 passed the corrosion test, 3 passed both tests, 3 failed under both tests, and one could not be fairly judged because the base metal failed in twisting. BENJAMIN MILLER

Alkaline electrolytic iron. STEWART J. LLOYD. *Am. Electrochem. Soc.* 1929,

(preprint) 7 pp.; cf. *C. A.* 15, 2591; 17, 1756.—The Estelle process is applied to pyrites roaster residue, limonite, red hematite, artificial $\text{Fe}(\text{OH})_3$, gray hematite and siliceous iron-bearing slag. Excellent results were obtained with the first two, fair results with the third and fourth and poor results with the fifth and sixth. The best conditions are: temp. 90° ; NaOH concn., 35%; ore ground to 200 mesh; thorough agitation; rotation of cathode; and c. d. 4 amp. per sq. dm. For 3 cm. spacing of electrodes the voltage is 2.5; the current efficiency is about 80%. Energy consumption is estd. at 3000–3300 kw. hrs. per ton of Fe. 75–85% of the SiO_2 and Al_2O_3 picked up from the ore could be pptd. by dilg. to a 20% NaOH concn. and adding $\text{Ca}(\text{OH})_2$. After re-toss as the cost of producing electrolytic Fe by this process in a 10-ton plant, with elec. energy at \$15 per h. p. yr.

BENJAMIN MILLER

The influence of current concentration in the electrolytic preparation of sodium perborate. F. GIORDANI AND R. INTONTI. *Rend. acad. sci. (Napoli)* [3], 34, 30–6 (1928).—The yield of sodium perborate, $(\text{NaBO}_2 \cdot \text{H}_2\text{O}_2 \cdot 3\text{H}_2\text{O})$, is high at low current density, as the loss of active O_2 is low; whereas, at high current density the yield is low because of decompn. of the perborate.

A. W. CONTIERI

The formation of perchlorate by electrolysis. A. V. PAMFILOV AND O. S. FEDOROVA. *Electrochem. Lab. Ivanovo-Voznesensk Polytechn. Inst. J. Russ. Phys.-Chem. Soc.* 60, 765–70 (1928).—Small quantities of NaClO_4 are formed in the electrolysis of aq. solns. of NaClO_3 even in the presence of 18% NaCl provided the c. d. is high (2 amps. per sq. cm.) When NaCl solns. are electrolyzed to form chlorate, the yield detd. chemically (FeSO_4 being used) is smaller than that calcd. from the vol. of gases given off. The formation of perchlorate (detd. colorimetrically with methylene blue) accounts for only a part of this difference.

B. SOYENKOFF

The electrolytic oxidation of methanol in alkaline solution. S. TANAKA. *Z. Elektrochem.* 35, 38–42 (1929). cf. *C. A.* 8, 2533, 16, 1078.— H is a product of the anodic oxidation of CH_3O and of MeOH in alk. soln. The theoretical explanation advanced for CH_3O cannot be used without modification for MeOH ; in the latter case H is evolved only at high-current densities, and then not to a great extent. To study the MeOH reaction, the following procedure was adopted: A soln. of NaOH (8 *N*) was mixed with an equal vol. of MeOH . The electrolyte so made was poured into a U-tube, in one arm of which was a Pt wire cathode, while in the other was a wire anode, 5 cm. long, 0.7 cm. in diam., of the metal to be investigated. By means of a potentiometer the voltage across the cell was raised stepwise, and at each setting the current and the potential of the anode against a normal calomel electrode were measured. The expt. was repeated with electrodes covered with Pt black. An earthenware diaphragm was placed between the electrodes, and electrolysis conducted for rather longer periods, with the potential between the anode and the calomel electrode kept approx. const. Three expts. were made with platinized Pt anodes, in one the anode potential was kept between -0.585 and -0.412 , in the second between -0.620 and -0.454 , and in the third between 0.00 and 0.02 v. After several hrs. the anolyte was analyzed for CH_3O and HCO_2H . The test for formaldehyde consists of treating the soln. under examn. with a satd. soln. of $\text{Cu}(\text{OH})_2$ in 12 *N* NaOH . A yellow ppt. of Cu_2O or a red ppt. of Cu in the deep blue soln. shows CH_3O if it is present in 0.002 *M* concn. or greater. Neither MeOH nor HCO_2H interferes. Since CH_3O was found absent in all cases, the estn. of formic acid consisted of heating to dryness, taking up the residue in water, adding NaHCO_3 to convert the NaOH to carbonate, and titrating with KMnO_4 . The first expt. showed a current efficiency of 97.7%, the second, 99.1% and the third, 70.8%. This indicates that in the basic range (potential negative) the only electrochem. reaction is the oxidation of MeOH to HCO_2H , while in the "noble" range (potential positive) there is some evolution of oxygen.

BENJAMIN MILLER

Electrolytic reduction of aldehydes. III. α - and β -Hydroxybenzaldehydes. G. SUMA. *Mem. Coll. Sci. Kyoto Imp. Univ.* [A], 11, 407–18 (1928).—Electrolytic reduction of salicylaldehyde to salicyl alc. is best carried out at 16 – 18° with a Hg cathode, an almost neutral catholyte, and a c. d. of 4 amp. 100 sq. cm. The yield of alc. is 85%. With an alk. catholyte there are formed dihydroxyhydrobenzoin (cf. Law, *C. A.* 1, 173) and 9,10-dihydroxy-9,10-dihydrophenanthrene. β -Hydroxybenzaldehyde gives a 92% yield of β -hydroxybenzyl alc. under the above conditions. IV. Vanillin and piperonal. *Ibid.* 419–27.—Reduction of vanillin suspended in a slightly acid catholyte at 8 – 10° gives hydrovanillin (10%) and 4-hydroxy-3-methoxybenzyl alc. (82%; *di-benzoyl* deriv., m. 130°). At higher temps. there is an increase in the amt. of hydrovanillin and other condensation products. In slightly alk. suspension the yield of

alc. is 92%. Under similar conditions piperonal gives a 90% yield of 3,4-methylenedioxybenzyl alc., m. 86° (lit. 81°; *benzoate*, m. 66°).

B. C. A.

Electrolytic oxidation of alcohols. III. Benzyl alcohol. S. KOMAZU, *Mem. Coll. Sci. Kyoto Imp. Univ.* [A], 11, 383-400 (1928).—Electrolytic oxidation of benzyl alc. in acid or alk. media gave, in most expts. made, a mixt. of benzaldehyde and benzoic acid. The expts. were carried out in a divided cell with a rotating cathode of iron plate, lead or nickel gauze, and a cathode soln. of either H_2SO_4 , NaOH, or Na_2CO_3 solns. enclosed in a porous cylinder. In acid soln. with Pb peroxide as anode material and Fe as cathode, the c. d. had no effect on the products formed but the amt. of aldehyde diminished with current quantity. With Pt or Au anodes and a Pb cathode, oxidation efficiency was low, but the product was almost free from benzoic acid. In Na_2CO_3 soln. the max. yield of benzaldehyde, free from benzoic acid, was about 71%. IV. Propyl alcohol in alkaline solution. *Ibid.* 391-400.—Electrolytic oxidation of MeOH in NaOH soln. at 15-17° at a Pt anode gives a mixt. of H 79-84.5, O 13.8-19.5, and CO 1.0-2.6% (cf. Müller, C. A. 15, 1511). After about 27 hrs. the proportion of H decreases rapidly, CO increases; CO_2 is formed also, presumably by oxidation of the aldehyde and acid produced. n-Propyl alc. in aq. MeOH NaOH soln. gives, in addn. to H, C_3H_4 and C_3H_6 , an increased amt. of the hydrocarbons being obtained at lower temps. The production of C_3H_4 is explained $CH_3Me-CH_2-O \rightarrow CH_3O + CH_3Me \rightarrow CH_3-CH_2 + H$; an analogous mechanism is suggested for the production of C_3H_4 during the electrolysis of propionates.

B. C. A.

The separation of hexone bases by electrolysis. TARO NOGUCHI, *Bull. Inst. Phys. Chem. Research Tokyo* 8, 153-5 (1929); *Abstract Ed.* 2, 22.—Solns. of amino acids have been electrolyzed in a 3-compartment cell. From the anodic compartment, the basic acids such as aspartic and glutamic acids were isolated. Suitable combinations of membranes and other conditions have been proposed. N. has used the hydrolyzates of casein and of ox blood, and has succeeded in isolating *arginine*, *histidine* and *leucine* from the cathodic compartment. By his method, it is not necessary to adjust the reactions of the solns. in the central compartment while the electrolysis is going on.

ALBERT L. HENNE

The electrolytic production of hydroxylamine. I. G. SICHERRAKOV AND D. M. LITINA. *Z. Elektrochem.* 35, 70-83 (1929).—Hydroxylamine can be produced by the electrolytic reduction of nitric acid at a Hg cathode in H_2SO_4 . The best conditions are: current density, 0.25 amp. per sq. cm., current concn., 10 amp. per liter, temp. 14-16°, HNO_3 concn. kept at N by continuous addn.; H_2SO_4 concn. 15 N at 1st, and 3 N at finish of run. The addition of HNO_3 should be discontinued before the end of the run, so that it may be used up as completely as possible. The remainder is removed by electrolysis with a Cu cathode, which reduces HNO_3 to NH_3 . The soln. made neutral to methyl orange, preferably with BaO, filtered, and the NH_4OH H_2SO_4 crystd. out. The current efficiency is 60-70%, and the material yield about the same. A voltage of 6 is assumed, leading to an estd. energy consumption of 16.7 kw. hr. per kg. of $NH_4OH \cdot H_2SO_4$. If impure HNO_3 be used a film forms on the Hg, causing 50% H_2 evolution and no reduction of the HNO_3 . During electrolysis *isomonoethylamine sulfate*, $(NH_4OSO_3H)_2H_2SO_4$, also is formed. This may be distinguished from $NH_4OH \cdot H_2SO_4$ by its property of oxidizing iodide ion to iodine in acid KI soln. During neutralization it hydrolyzes to form NH_4OH .

BENJAMIN MILLER

The solution of plain and amalgamated zincs in electric batteries. J. NEWTON FARRAR, *J. Inst. of Metals* 1929 (advance paper) No. 494, 4 pp.; *Engineering* 127, 645 (1929).—The objects of the investigation were to det. whether (1) 99.99% Zn, or amalgamated, could be used in place of amalgamated commercial 98-99% Zn in elec. batteries, or (2) failing this, whether amalgamated pure Zn would be better. The ordinary Zn tested contained Zn 98.82%, Pb 1.12%, Fe 0.05%, and As 0.008%. The impurities in the "pure" Zn are not stated. The expts. showed that pure Zn corroded more rapidly than amalgamated ordinary Zn in 10% H_2SO_4 , and in acid. NH_4Cl , that amalgamated pure Zn corroded more rapidly than amalgamated ordinary Zn in 10% H_2SO_4 , and that there was very little difference in the behavior of amalgamated pure Zn and amalgamated ordinary Zn in acid. NH_4Cl . No change from present practice is recommended.

BENJAMIN MILLER

The zinc electrode in dry cells. C. DEUTSCHMANN, *Chem.-Ztg.* 53, 29-31, 70-2, 65-6 (1929).—The Zn can of the dry cell is rapidly corroded by the electrolyte if the $HgCl_2$ is omitted, but is not attacked if amalgamation has been thorough. Amalgamation at room temp. in an electrolyte contg. 200 g. NH_4Cl , 75 g. $ZnCl_2$, and 4 g. $HgCl_2$ in 1000 g. H_2O is a slow process. After 4-5 days the Zn looks amalgamated, but several more days before the process is complete. When the meal is added amalgamation

is completed in a few hrs., while the cooking process used to set the paste causes the amalgamation to be completed in a few min. With a given electrolyte contg. a definite amt. of meal in suspension, the time required for complete amalgamation depends on the temp. and on the amt. of Hg salt in soln. With the electrolyte men-----, which was added 170 g. of yellow corn meal, amalgamation required 8 mins. at 60–65 or 4 mins. at 70–75°. With only 2 g. of HgCl_2 , 3 mins. sufficed at 70–75°, while 8 g. prolonged the time to 10 mins. at the same temp. Since the time and temp. of cooking depend on the meal being used, the proper amt. of HgCl_2 can be detd. The use of excess Hg salt does not give greater capacity, as has been claimed, but is injurious in that the longer cooking time required for amalgamation spoils the structure of the paste. Too small an amt. of Hg salt causes the amalgamated layer to be more brittle. In some cells made up with the anode assembly, irregularities appeared in the Zn surface. These took the form of craters, which started to appear about 12 hrs. after cooking, increased in number and depth up to 48 hrs., and then remained const. They had no influence on the quality of the cells when new, but after 10–12 months the paste became hard through crystn., whereas cells without craters were still moist. Expts. showed that this effect is due to different electrolyte concns. at various parts of the cell. If the Zn is kept from touching the outside covering of the anode assembly, the craters do not appear. It is therefore essential for long shelf life that the anode assembly be centered carefully, and that the insulating material coming next to the Zn be one which cannot cause changes in electrolyte concn. Expts. with specially cleaned, ordinary and deliberately soiled Zn showed that amalgamation was not affected by dirt, and that at the same time it protected against ill effects from accidental dust. Thin grease films were also without effect. To test the effect of foreign metals, 3 groups of cells were made up with Pb, Cu and Fe wires soldered to the Zn. A 4th group had several drops of solder on the inside surface. Precautions were taken to prevent the contact of foregoing metal and C, but otherwise the cells were cooked and sealed in the usual way. No difference in capacity was observed between the 4 groups and a fifth control group, either when new or at the end of 12 months. The paste in the vicinity of the Cu and Fe wires showed slight discoloration. Two groups of cells were made up with high-As and high-Pb Zn: one contained 0.84% Pb and 0.32% As, while the other contained 1.82% Pb and 0.002% As. The high-Pb cells showed slightly less capacity than the controls, and after 10 months deteriorated rather rapidly. The high-As cells had considerably less capacity than the controls, and after 10 months corrosion became so rapid that at least one cell in every battery had perforated at the end of 12 months. These results do not agree with the "local action" theory. Though the presence of foreign metals in the Zn is harmful only insofar as they influence the surface of the can, they are very deleterious when they occur in electrolyte-sol. form in anode assembly, insulation or electrolyte. Reducing agents, such as Fe^{++} , use up the depolarizer. Metals more noble than Zn are pptd. by it, wasting the latter and injuriously increasing the ZnCl_2 concn. An addn. of 1% As_2O_3 to the anode assembly decreases the initial e. m. f. from 1.55 to 1.47 v., reduces the short circuit current from 8 to 4.3 amp., reduces the time to 0.6 v. at 5 ohms from 4 hrs. 15 mins. to 3 hrs. 15 mins., and hardens the paste so that the cell is dead after 5 months on the shelf. Occasionally cells are produced which deteriorate in capacity and short circuit current in 5–14 days, although they have a const. initial e. m. f. of 1.5 v. In 2–3 months on the shelf the cans have corroded badly. Such cells, on being opened after discharge at the 5-ohm rate, or after standing without load 5–8 days, show a characteristic darkening of the Zn surface, which cannot be washed off. Neither analysis of the stain nor microstructure of the Zn showed the cause of this effect. By successively changing the ingredients in the cell, it was finally found that the MnO_2 was at fault. In another case the effect was traced to a meal of excessive gluten content. Poor insulation between Zn and C may have the same effect, which indicates that it is due to a high-resistance internal short circuit. The mechanism is not offered, except for the remark that the high-gluten meal caused the establishment of concn. cells. The suitability of a Zn for dry-cell use may be shown by the following test: 3 sheets, 50 mm. square, are quartered, and each of the 12 pieces is bent to a 90° angle. Four of the pieces are dropped into a Dewar flask contg. 50 cc. of 10% H_2SO_4 ; a two-hole stopper, carrying an accurate thermometer, is put into the mouth of the flask. A minute later 4 pieces are put into a second flask in the same way. A third set is placed in another flask. At the end of a min. the temp. of the first one is read. The thermometers are read at 1-minute intervals. The starting temp. is 11–13°. The time-temp. curve should be smooth. If at the end of 30 mins. the temp. has gone above 30°, the Zn is rejected.

BENJAMIN MILLER

Hot-cathode thyatrons (rectifier). I. Characteristics. ALBERT W. HULL. Gen.

Elec. Rev. 32, 213-23(1929).—The thyatron is an arc rectifier with electron-emitting cathode of pure W, thoriated W or Mo, barium-coated Ni (Wehnelt cathode), cesium-coated, or of Hg, whose starting is controlled by a grid, which completely surrounds the anode; after starting, the grid has no further control over the arc. The arc is extinguished by removing anode voltage; upon reapplying voltage the grid again controls starting of the arc, and by repetition of this procedure the grid serves to control the av. current. The small type of thyatron has a filament construction similar to that of vacuum tubes but the larger types require massive construction. Correct pressure, purity and constancy of gas in the tube must be maintained. For Hg the best range of pressure is between 1 and 50 microns; for other gases it is somewhat higher. Exhaust must be continued until a high vacuum is obtained before introduction of gas filling, since gas impurities are very undesirable, poisoning the cathode, increasing arc drop and causing loss of grid control. Expt. has proved that "monatomic gases will clean up very little if at all in the thyatrons, provided voltage drop is kept below disintegration value." Various types of thyatrons are illustrated and their characteristics are plotted.

M. McMAHON

Burn-out of incandescent lamps. A discussion of the phenomena influencing the life of gas-filled lamps. GORTON R. FONDA. *Gen. Elec. Rev.* 32, 200-12(1929).—The gas-filled lamp is characterized by low loss in wt. of filament (about 3%) at burn-out as compared with the vacuum lamp, which burns out at about 10% decrease in weight of filament. The causes underlying the behavior of gas-filled lamps were investigated by studying the tensile strength, crystalline changes, disintegration of filament under chemical changes and influence of ionization of the gas. Tensile-strength measurements were made of "218" or non-sag W wire, of W wire with 1.5% ThO₂ and of Pintsch wire contg. about 2% ThO₂; life tests on these filaments in gas showed no particular effect of tensile strength on burn-out. Photomicrographs showed striking changes in crystal structure of filaments on burning in gas due to evaporation phenomena in gas-filled lamps (*C. A.* 17, 2069; 23, 1509). The effect of gas on the life of filaments was apparent; for filament 1.6 mm. in diam. and 12 cm. long at 2870° K. in nitrogen the loss in weight at burn-out was 4.7%, in 80% A 6.7% and in 100% N 8.2%. The arcing in gas-filled lamps and its harmful effects were considered; reduced gas pressure and reduced spacing of the terminals caused leakage currents which might affect the life of the filaments under abnormal conditions.

M. McMAHON

Electrical precipitation. A. GROUNDS AND H. W. C. HENDERSON. *Elec. Rev.* (London) 102, 700-8(1928); *Science Abstracts* 31B, 437. An illustrated description of a Lodge-Cottrell industrial plant for the pptn. of dust particles from flue and other gases. There are two types: (1) a fine-wire electrode is suspended from an insulator in a vertical tube through which the gases pass; (2) the gases pass between plate electrodes. In each case the electrodes are maintained at a potential difference of about 50-60 kv. by a synchronously driven rectifying switch and transformer. The particles in the gas are ionized by collision and are driven by the intense field to the electrode and there deposited. At intervals of 3 to 4 hrs. the accumulated dust is removed by rapping, either by hand or by means of a machine. Typical plants are described handling up to 2 million cu. ft. a min. Tests show that a suitable plant can nearly always be designed to extract practically all the solid matter in the gases.

H. L. D.

Electrical purification of blast-furnace gases. KERALY. *Bull. soc. franç. élec.* 7, 136-55(1928); *Science Abstracts* 31B, 362-3. After a résumé of the methods ordinarily employed hitherto for the removal of dust from blast-furnace gas for use for power purposes, the author deals with elec. pptn. by passing the gas between parallel electrodes at a considerable difference of potential. The theoretical aspect of the question is briefly treated, and it is shown that the most favorable conditions are obtained with cylindrical electrodes. Continuous, or rather rectified, potentials are more efficient than alternating potentials because there is partial recombination of ions at each reversal in the latter case. An installation at the Dilling steel works is described. A pressure in the neighborhood of 50,000 v. is employed and is obtained by step-up transformers from the 500-v. 50-cycle supply. A commutator-type rectifier driven by a synchronous motor is used. The plant has a normal capacity of 12,000 cu. m. of gas (this being presumably per hr.) with considerable overload capacity and comprises 6 chambers, each contg. 2 groups of 7 vertical tubes, with central insulated electrodes, through which the gas is passed in an upward direction. Arrangements are made for periodically passing a counter-current of purified and reheated gas down the tubes to blow the collected dust out to the bottom of the chamber, while the tubes are vibrated by pneumatic hammers, which form part of the app.; the dust collecting at the base of the chamber is removed by a screw conveyor. The actuation of the necessary valves for this periodical

cleaning of each chamber is automatic. The app. is stated to work satisfactorily and to reduce the dust content of the gas from 4-6 g. per cu. m. to 0.025-0.002. The system has the advantage over wet processes of not needing large quantities of water and space for settling tanks; over other dry processes the further advantages are claimed of simplicity, less necessity for accurate temp. control, lower maintenance costs and lower power consumption. H. G.

Power factor and dielectric constant in viscous dielectrics. DONALD W. KITCHIN. Simplex Wire & Cable Co., Boston. *J. Am. Inst. Elec. Eng.* 48, 281-4(1929).—A study is made of the peculiar variation with temp. and frequency of the dielec. const. and power factor of *rosin*, *rosin oil* and *castor oil*, including data showing at several frequencies the relation of dielec. const. and power factor to the compn. of vulcanized rubber. Viscosity is shown to be a decisive factor controlling the elec. and optical behavior of rosin. The Debye dipole theory is outlined and the exptl. results are discussed on its basis. The behavior of viscous, homogeneous liquid dielectrics with respect to the change of power factor and dielec. const. with temp. appears best interpreted on the basis of molecular orientation according to this dipole theory—particularly the theory of anomalous dispersion and absorption. The elec. behavior of *rubber-S* compds. is discussed and it is claimed to be possible to predict qualitatively some elec. features that should be observed if the application of the orientation theory to rubber is permissible. There is a characteristic frequency for each compn. in the region where dipole molecules exist, the softer the rubber, the higher the characteristic frequency; the maxima in the dielec. const. and power factor occur at lower S contents the higher the applied frequency. A thorough study of the elec. properties of vulcanized rubber might throw considerable light on the nature of the vulcanization reaction. The application of the orientation hypothesis to rubber is only tentative and considerable critical exptl. work would be needed to place it on as firm a basis as in the case of viscous liquids. W. H. BOYNTON

Hydrogen cooling of large electrical machines. C. J. FECHHEIMER. *Elec. J.* 26, 127-30(1929). For high-speed app. such as steam turbine generators and synchronous condensers the substitution of H for air as the cooling medium effects reduction in windage losses and removal of harmful corona effects. The expense of modifying machines for this substitution limits its use to large machinery. M. McMAHON

The electric light sources for photomicrography. MASAO KURODA. *Bull. Inst. Phys. Chem. Research Tokyo* 8, 80-93(1929); *Abstract Ed.* 2, 11. —Types of small incandescent lamps are compared with a W arc lamp and a C arc lamp. Tests show that an incandescent lamp is preferable to arc lamps for small laboratories. A. L. H.

Chemical problems in the manufacture of cables (ADEL) 13. Be and its chloride (SCHMIDT) 6. Hydrogenation of coal, etc. (Fr. pat. 647,981) 21. Porous metallic plates or objects, particularly for storage batteries and the like (Belg. pat. 351,859) 1. Molded articles [storage-battery boxes] (U. S. pat. 1,707,585) 18. White enamel for incandescent lamps (U. S. pat. 1,708,743) 19. Treating hydrocarbon oils with corona arc discharges (U. S. pat. 1,708,126) 22. Rubber electrodeposition (Brit. pat. 296,138) 30.

Illustrated Technical Dictionaries. Vol. 2. **Electrical Engineering and Electrochemistry.** In six languages. Edited by Kurt Deinhardt and Alfred Schlomann. Berlin: Technische Wörterbucher-Verlag G. m. b. H. 1304 pp. Reviewed in *Chem. Markets* 24, 379(1929); *Metal Ind.* (London) 33, 412(1928).

Electric battery of the Bunsen type. H. KÖHNE and W. SUHRCKE. Brit. 296,184, July 28, 1927. Structural features.

Jars for electric batteries. J. E. MARSDEN. Brit. 296,613, Jan. 2, 1928. An inner glass container is formed with partitions and with electrode supports extending upwardly from its bottom and is enclosed in an outer casing of asbestos, cork, mineral plaster, cellulose, or other suitable material with an intervening layer of non-hardening material such as asphalt or tar. Various structural details are described.

Dry batteries. COMPAGNIE FRANÇAISE POUR L'EXPLOITATION DES PROCÉDÉS THOMSON-HOUSTON. Fr. 647,180, June 4, 1927. Constructional details.

Contact head for dry batteries. GEHR. KLEINMANN. Fr. 647,616, Jan. 23, 1928.

Storage batteries. JACQUES DELPECH and EUGÈNE VACHERON. Fr. 647,940, Jan. 30, 1928. Celluloid, ebonite, or synthetic resins are used as the support for the active material. The surface is rendered conductive by surface metallization, etc.

C. H. EVERETT and G. H. CARR. Brit. 296,660, Sept. 3, 1927.

Structural features.

Storage battery. G. M. RADULESCU (to A. Sismanopol, trading as Forta Intreprinderi Electro-Mecanice). Brit. 296,990, Sept. 10, 1927. The neg. electrode is formed of Pb coated with electrolytically deposited Cu and its area is less than half that of the pos. electrode, which is formed of PbO_2 . The lower end of the neg. electrode rests on the bottom of the container and the lower end of the pos. electrode is supported above the bottom.

Storage batteries. COMPAGNIE GÉNÉRALE D'ÉLECTRICITÉ. Fr. 647,287, Nov. 30, 1927 and Fr. 647,289, Dec. 2, 1927.

Storage batteries. I. G. FARNHIND. A.-G. Fr. 647,900, Jan. 28, 1928. Plates are made by forming a grating of Pb and prisms of Pb alloy which fit exactly into the cells of the grating, introducing the prisms by pressure and alloying the metal by soln. By this means alloying of the added metal with the Pb of the grating is prevented.

Electrode for "alkaline" storage batteries. ALLAN LEVIN (to Svenska Ackumulator Aktiebolaget Jungner). U. S. 1,708,889, April 9. Structural features.

Hydrometer suitable for testing storage battery electrolyte. J. H. COLLIER. Brit. 297,167, July 2, 1927. Structural features.

Electroplating non-metallic surfaces. K. BARANOWSKI. Brit. 297,260, Dec. 21, 1927. A cond. compn. for application to non-metallic surfaces prior to electrodeposition of metal on them is prepd. by boiling "carbon, soot, or synthetic graphite" with a dild. alc. or ether and adding a small quantity of water from time to time until the volatile solvent is completely evapd., then mixing the powdered product with "sol. glass" and heating the mixt.

Electric immersion heater for electroplating baths. H. ZANDER. Brit. 297,225, Oct. 1, 1927. Silica bars are connected in series or parallel and mounted in a casing which may be formed of Pb. Various structural features are described.

Cadmium plating. GUSTAVE J. DELATRE. Fr. 647,248, June 9, 1927. Salts of Sn, Ni, Cu, Zn, either singly or together, are added to the electrolyte to obtain a mixed deposit on the article to be plated. Thus, a deposit may be obtained from a soln. of sulfates of Cd and Ni contg. Cd 90 and Ni 10%.

Chromium plating. ERIC LIEBRICH. Fr. 33,527, Feb. 15, 1927. Addn. to 533,363. In the production of a Cr deposit by electrolysis of oxides of Cr, the reduction of the chromic acid is assisted by the addn. of finely divided cellulose, paper or the like, or albumin, pepsin, peptone or the like. Finely divided Al or Mg may also be added.

Coating with chromium. HARRY SCHMIDT. Ger. 472,157, Apr. 2, 1926. A fused borate melt contg. dissolved Cr is electrolyzed at a sufficiently high c. d. to cause sepn. of B-Cr. An example is given in which a bath contg. $Na_2B_4O_7$ 90 and Cr_2O_3 15 parts is electrolyzed at 950° with a c. d. at the cathode of 10,000 amp./sq. in.

Chromium electrodeposition. P. LAUTERBACH (to W. G. Poetzsch). Brit. 296,188, Sept. 10, 1927. An electrolyte is used comprising chromic acid with the addn. of a small quantity of an oxide or salt of Al or Mg (suitably the sulfates). The Al and Mg are not deposited. The total free and combined H_2SO_4 should not exceed 1.5% and should preferably be about 0.6-0.7% of the CrO_3 present. Brit. 296,189 specifies removing excess H_2SO_4 from Cr-plating baths consisting mainly of chromic acid, by addn. of a calcd. quantity of a Ba compd. such as $Ba(OH)_2$ or $BaCO_3$.

A non-oxidizable metallic coating. ÉLECTROLYSE BELGE ELPEWE. Belg. 352,106, June 30, 1928. Cd is deposited electrolytically, the object to be coated being the cathode and Cd plates the anode. The electrolyte consists of a soln. of a Cd salt and a cyanide.

Electrolytic cell. I. G. FARNHIND. A.-G. (George Pfeiderer, inventor). Brit. 471,925, Nov. 13, 1923. In an electrolytic cell, particularly for decompng. water, the elec. elements are arranged one behind the other and the electrolyte within each element is circulated by side spaces up the dividing walls.

Electrolytic preparation of matrices for sound records. GRAMOPHONE CO., LTD. and S. WYVRA. Brit. 296,459, May 2, 1927. An original record of wax or so. like material is brushed with finely divided Cu or a mixt. of Cu and graphite, coated with a Ag mirror by a reduction process; matrix metal is then deposited electrolytically on this prepd. surface. Various details are given.

Electrolytic recovery of metals from ores. L. GRUNSMAN. Belg. 352,106, July 31, 1928. The ore and an acid soln. are circulated in opposite directions, so that the ore comes in contact with acid of increasing concn. and temp. as its metal content decreases.

The soln. of the metal is then passed through a layer of sulfide of the same metals so as to displace the metal from the sulfide by the metallic impurities in the soln. before subjecting the latter to electrolysis. An app. is described. The process is particularly suitable for the extn. of Zn.

Apparatus for electrolytic mass production. LANGBEIN-PFANHAUSER-WERKE A.-G. Ger. 472,092, July 7, 1926. Addn. to 471,260. Modifications in the app. of Ger. 471,260 (C. A. 23, 2110) are described.

Aluminum alloys. VEREINIGTE ALUMINIUM WERKE A.-G. Fr. 646,990, Jan. 11, 1928. Al-Si alloys are made by the electrolysis of a fused mass in the bath of fluoride used for the extn. of Al, the Si being added in the metallic state.

• **Alkali chlorates.** VEREIN FÜR CHEMISCHE UND METALLURGISCHE PRODUKTION. Fr. 647,052, Jan. 13, 1928. In the electrolytic manuf. of alkali chlorates the danger of explosion is avoided by adding a gas free from or contg. little O to the mixt. of H and O. The O may be sepd. from the gaseous mixt. by a catalytic reduction.

Aluminum. SOCIETÀ ITALIANA DI ELETTOCHIMICA. Ger. 472,085, May 21, 1927. See Fr. 634,727 (C. A. 22, 3847).

Aluminum. I. G. FARBENIND. A.-G. Fr. 647,856, Jan. 6, 1928. See Brit. 283,949 (C. A. 22, 4071).

Cerium. FRITZ SOMMER (to Deutsche Gasglühlicht-Auer-G. m. b. H.). U. S. 1,707,450, April 2. In sepg. Ce from assocd. impurities such as didymium, Fe and La, a supersatd. cerous salt soln., which will yield a basic ceric salt by electrolytic oxidation, e. g., a soln. of cerous sulfate, is subjected to electrolytic oxidation at the anode; the basic ceric salt formed is sepd.

Copper. KASPAR WALTER. Ger. 471,576, Dec. 28, 1927. A device for polishing Cu ppt. during the coppering process in a galvanic bath consists of a cylinder with oblique polishing elements between which the ppt. slides as the cylinder rotates.

Hydrogen. C. EPNER. Brit. 206,428, Sept. 2, 1927. H or gases contg. H are obtained by treating hydrocarbon-contg. gases such as coke-oven gas with an a.-c. elec. field of high frequency and high tension, either at normal or elevated temps. Liquid products are obtained from CO and other C compds. present. Less volatile substances may be removed from the products by compression, use of oils, active C, silica gel, etc.

Electrolytic manufacture of oxygen and hydrogen. JOHN P. SCOTT. Ger. 472,398, July 26, 1922. See Brit. 210,102 (C. A. 18, 1617).

Ozone. EDMUND KUREK. U. S. 1,708,067, April 9. Air is introduced into the central portion of a receptacle in which an abrasive wheel revolves in contact with a steel tube or bar. The sparks thus generated serve to form O₃ and the receptacle is rotated to effect centrifugal concn. of the O₃ in an outer zone of the receptacle whence it is drawn off; residual gas high in N is withdrawn from the central portion of the receptacle. Various structural details are described.

Ozonizer. JOHANNES KUHLENSCHMIDT. Ger. 472,344, Mar. 27, 1927. In an ozonizer of the kind having no dielectric between the electrodes and at least 1 electrode subdivided into a no. of electrodes arranged in parallel, an impedance, preferably a condenser, is arranged in advance of each single electrode.

Electric furnace. FRIEDRICH SIEMENS A.-G. Ger. 471,525, Nov. 21, 1926. Addn. to Ger. 418,779. A d.-c. furnace has several sep. longitudinal chambers provided with regulatable means for leading off the gases.

Electric furnace for the reduction of oxides of metals. TURE R. HAGLUND. Fr. 647,952, Jan. 30, 1928.

Electric furnace for metals and alloys. ÉMILIEN BORNAND and HANS A. SCHLAEPFER. Fr. 646,964, Jan. 11, 1928.

Electric furnace for gas reactions. M. GOBERT. Brit. 206,642, March 14, 1928. Arc electrodes are in the form of disks mounted on rotary shafts so as to be movable lengthwise of the shaft to adjust the length of the arc. Various details are described.

Electric arc furnaces. SOC. D'ÉTUDES ET DE CONSTRUCTIONS METALLURGIQUES and GASTON GARNIER. Fr. 33,659, Feb. 22, 1927. Addn. to 624,280. A regulator for the current is described.

Electric induction furnaces. PAUL E. BUNET and ACIÉRIES DE GENNEVILLIERS. Fr. 647,152, 647,153 and 647,154, June 2, 1927.

Electric induction furnace for melting metals. O. GOTZE. Brit. 297,313, Sept. 17, 1927. The surface of the metal charge is heated by a naked flame in contact with the metal which serves to ensure complete melting when the charge is composed of shavings or waste mixed with oil or dirt. The air supply is controlled to produce a reducing flame, and a slightly super-atm. pressure may be maintained in the furnace (which is described).

Electric induction furnace for melting and refining, etc. E. F. NORTHROP. Brit. 296,464, May 30, 1927. Structural features.

Electric induction furnace for annealing metal articles. HIRSCH KUPFER- UND MESSINGWERKE A.-G. and M. TAMA. Brit. 297,311, Sept. 17, 1927. Various structural features are specified.

Electric resistance furnace for annealing metal articles in a gas-tight container. WILLIAM J. DIEDERICHS (to Westinghouse Elec. & Mfg. Co.). U. S. 1,707,300, April 2. Structural features.

Electric resistance-heated receptacle suitable for melting solder, babbitt metal, etc. ALVIN D. KEGNE (to Westinghouse Elec. & Mfg. Co.). U. S. 1,707,308, April 2. Structural features.

Electric vacuum furnace suitable for preparing vitreous silica. PHILIP K. DEVERS (to General Electric Co.). U. S. 1,708,833, April 9. Structural features.

Electrically heated oven. G. MELVILLE and MEASUREMENT, LTD. Brit. 296,552, Aug. 31, 1927. Various structural features of an elec. resistance-heated oven are described.

Cooling means for the conductors of induction furnaces. METROPOLITAN-VICKERS ELECTRICAL CO., LTD. Fr. 647,412, Jan. 17, 1928.

Electrodes for electric furnaces. PAUL L. J. MIGUET (to Soc. Électrometallurgique de Monfricher). U. S. 1,707,406, April 2. Structural features are specified relating to electrodes with coupled exterior sectors and a core filling.

Electrode spacing in cells. J. L. WOODBRIDGE. Brit. 297,246, Nov. 23, 1927. Structural features.

Rectifying elements of superficially cleaned silicon carbide. MINER L. HARTMANN and MORROW C. MILLER (to Carborundum Co.). U. S. 1,708,571, April 9. The surface of a fragment of silicon carbide is freed from associated impurities incidentally present from its manuf., e. g., by successive treatments with NaOH, HNO₃, and HF. U. S. 1,708,572 relates to detectors in which such superficially purified silicon carbide fragments are used in contact with a hard, flat plate of metal such as steel.

Electrolytic rectifier. S. D. WHITE and R. J. JONES. Brit. 296,641, March 13, 1928. An anode of 99.5% Al and a cathode of iron hardened and rendered resistant to corrosion by the addn. of W and Co are used with an electrolyte of a mixed soln. of molybdic acid, H₃PO₄, tartaric acid, oxalic acid, or acetic acid, NH₄ phosphate and Al acetate. Various structural details are described.

Full-wave electrolytic rectifiers. S. D. WHITE and R. J. JONES. Brit. 296,610, March 13, 1928.

Electric rectifiers of the copper-copper oxide type. SIEMENS-SCHUCKERTWERKE A.-G. Brit. 296,606, Sept. 3, 1927. Air ducts are provided for cooling and a heat cond. material such as Al may also be interposed between the electrodes for cooling purposes.

Electric rectifier units with ribbed plates of metal such as copper carrying an oxide coating. CLARENCE E. OGDEN (to Kodak Radio Corp.). U. S. 1,707,234, April 2. Structural features.

Electric-discharge apparatus. J. W. MARDEN (to Westinghouse Lamp Co.). Brit. 296,778, Sept. 8, 1927. Leakage between conductors of discharge tubes containing an alkali metal vapor is prevented by coating the insulating surfaces between the conductors with a mineral oil substance, which is non-volatile at the temps. to which the device is subsequently exposed. Petrolatum, which has been heated to 300-400° at a pressure of 1 or 2 cm., is suitable and may be applied dissolved in CHCl₃. To introduce the alkali metal vapor into the tube, a capsule of a compd. such as Cs₂Cr₂O₇ or CaMnO₄, mixed with a reducing agent such as Si, or of a mixt. of CsCl and Ca may be welded onto the anode support and heated by high-frequency induction currents.

Electric gas purification. METALLGESELLSCHAFT A.-G. Ger. 471,732, Aug. 22, 1928. App. is described.

Electrical dust-precipitating plant for gas purification. SIEMENS-SCHUCKERTWERKE A.-G. (Oscar Heymann, inventor). Ger. 471,795, Mar. 2, 1923.

Apparatus for electrical precipitation of suspended matter from gases. LORRÉ CORRELL, LTD. (Lurgi Apparatebau Ges.). Brit. 296,956, March 28, 1928. Structural features.

Electric rotary drying machine. SIEMENS-SCHUCKERTWERKE A.-G. (Adalbert Major, inventor). Ger. 471,521, Aug. 11, 1927. The cover of an elec. drying machine is prevented from opening during motion by a member under the influence of the cooling current of air.

Light rays for therapeutic purposes and for promoting plant growth. SIEMENS &

HALSKE A.-G. Brit. 296,724, Sept. 6, 1927. Rays are used having a wave length of 350-360 μ m; rays below 320 μ m are excluded. An arc lamp may be used with one electrode of Zn or Ag or Ag-cored material and the arc may be attenuated by such means as a "gas jacket in motion" having a quartz envelope or choke. Various specified color screens may be used to filter out undesired rays.

Leading-in wires of electric lamps, etc. W. DAWSON. Brit. 206,453, March 3, 1927. In forming leading-in wires and supports for elec. lamps and *thermionic valves*, a base of Ni-Fe is dipped into molten Zn and the coated base is heated in H to slightly above the m. p. of Zn; the metal is then drawn into strips or wires and these are passed between (but out of contact with) C plates immersed in a soln. of $K_2Cr_2O_7$ and H_2SO_4 while an elec. current is passed between the C plates.

Electric incandescent lamps for high-intensity projection use. NAAMLIOOZE VENNOTSCHAP PHILIPS' GLOELAMPENFABRIEKEN Brit. 297,170, July 4, 1927. A reflector is provided on the inner surface of the bulb and disintegration of the reflecting surface may be prevented by a coating of siliceous varnish or other suitable material.

Filaments for electric incandescent lamps. NEEL GLULAMPEN GES. (to Falk Stadelmann & Co., Ltd.) Brit. 297,052, Sept. 13, 1927. Single- or long-crystal W wire is used for making filaments for searchlights or for other high-intensity lamps, of spheroidal or ellipsoidal form, comprising 2 calotte-shaped coils with their largest turns united. Cf. C. A. 22, 2518.

Metallic cesium. RICHARD E. MIESSE (to New Process Metals Corp.). U. S. 1,707,637, April 2. A mixt. of $CsCl$ and a rare earth metal alloy reducing agent such as misch metal is placed in a closed glass vessel; the vessel is evacuated to less than 0.001 mm. Hg and heated to about 270° or higher while being exhausted to remove occluded gases from the surfaces inside the vessel, and finally the mixt. of Cs salt and reducing agent is heated in the evacuated vessel by an elec. current to effect reduction of the Cs. An app. is described.

C. E. K. MEES

Additivity of photographic densities. G. TICHOW. *Bull. Acad. Sci. Leningrad* 1927, 511-32; *Chem. Zentr.* 1928, I, 464. A study of the density produced by 2 light sources acting together, the density due to each separately being known. Stellar exposures were made experimentally and the results agree with those detd. by a calcn. in which the relation between the density and the intensity of exposure was known. C. E. K. M.

Use of standardized H. & D. curves in sensitometry. O. E. CONKLIN. *J. Optical Soc. Am.* 17, 463-5(1928). A set of transparencies contg. 413 standardized curves is described. One of these may be superimposed on the points of any H. & D. graph cor. for fog and may be used for detg. accurately the speed, gamma and other characteristics of the emulsion under investigation. M. S. VINCENT

Law of blackening of the photographic plate at low densities. E. A. BAKER. *Proc. Roy. Soc. Edinburgh* 48, 106-33(1928), cf. C. A. 19, 2458; 21, 2853.—A theory is developed in which each grain of a photographic emulsion is assumed to act as an absorbing and emitting system, the rate of development of the grain depending on the particular sequence of absorptions and emissions which it has undergone. Comparison of the theoretical results obtained when the proportion of grains which suffer given sequences of absorptions and emissions is small, with exptl. detns. of the variation of d. with exposure time, indicates that the grain requires 2 successive absorptions or 3 absorptions with one intermediate emission to render it susceptible, resp., to "full" or "partial" development. The development is "partial" when it is stopped at an early stage so that the grains developed are selected from those belonging to a small group of states of very similar properties. Development sufficient to blacken grains which have been reversed by short exposure to intense light is termed "full." The results apply over the whole range of wave length tested, from 480m μ to below 200m μ . A quant. theory of the action gives good agreement with the facts relating to pre-exposure, inefficiency of short exposure to intense light, proportions of grains affected by different exposures in single-layer plates (for small grains) and influence of development on Schwarzschild's index. In the case of the "curves of constant blackening" there is a disagreement between theory and experiment for long exposures, which indicates that the "emission," though spontaneous, does not obey the unimol. law. A new formula

for the characteristic curve of a plate with uniform grains, successful over the low and moderate d. region, is derived. B. C. A.

Practice of developing fine-grained images. A. LUMIÈRE, L. LUMIÈRE AND A. SEYEWITZ. *Sci. ind. phot.* 8A, 126-8(1928); cf. C. A. 23, 48.—Three methods of producing fine-grained images are: (1) phys. development after fixation; (2) use of a paraphenylenediamine-sulfite developer contg. $\text{Na}_2\text{B}_4\text{O}_7$ or Na_2CO_3 ; and (3) development with elon and hydroquinone developers contg. a large excess of sulfite and little alkali such as borax (E. K. borax developer) or Na_2CO_3 (Namias' formula). L., L. and S. have previously found that phys. development after fixation gives very fine dichroic images. Such phys. development methods are not practicable for ordinary processing. In recent tests a very slow (45 mins.-1 hr.) metol-hydroquinone formula gave as fine a grain as was obtained in the regular Eastman borax developer. The finest-grained images were obtained by developing for 1 hr. in the following formula: paraphenylenediamine (base), 10 g.; Na_2SO_3 (anhyd.), 60 g.; $\text{Na}_2\text{B}_4\text{O}_7$, 50 g.; H_2O to 1 l. Photomicrographs of the image grain obtained in the different developers are given.

L. E. MUEHLER

Metallic reflection effects by the action of dyes on photochemically mordanted gelatin. A. REYCHLER. *Bull. soc. chim. Belg.* 37, 403-8(1928).—A dichromated gelatin-coated plate printed as in the Pinatype process may be further dyed in a soln. of a basic dye, to give a metallized image which is a negative by reflected light. Suitable pairs of dyes and concn. are prescribed. An acid dye, such as eosin, which is not very appreciably affected by dichromate, may be incorporated in the film, when the procedure after the first printing can be varied to give either a negative or a positive metallized image. Finally, R. describes some properties of the salt-like substance obtained by mixing, *in vitro*, a soln. of acid violet and cryst. violet. E. R. BULLOCK

WALL, E. J.: Practical Colour Photography. London: Chapman & Hall. 280 pp. 15s. net.

Color photography. JENS H. CHRISTENSEN. Fr. 647,008, Jan. 1928. See Ger. 469,578 (C. A. 23, 1072).

Color photography. WM. T. TARBIN. Fr. 647,571, Jan. 21, 1928. See Brit. 283,765 (C. A. 22, 4073).

Color photography. EMIL WOLFF-HEIDE. Ger. 471,508, Jan. 7, 1927. Sensitized layer carriers are exposed, developed and fixed. The Ag image is either converted into a color-repelling compd., or the gelatin contg. the Ag hardened so that the part-negative desired to be formed by subsequent exposures is protected from the action of the developing soln.

Optical systems for color photography. MERRILL W. SEYMOUR (to Eastman Kodak Co.). U. S. 1,708,370-1, April 9.

Color cinematography. A. PILNY and O. PILNY. Brit. 296,422, Sept. 1, 1927. Optical features.

Photographic diazotype process. KALLE & Co., A.-G. Brit. 296,725, Sept. 6, 1927. Sensitive layers which yield pos. prints from neg. originals are produced by applying on a base a mixt. of 2 or more different diazo compds. which are preferably of different sensitiveness to light (or if of the same order of sensitiveness are mixed in different mol. proportions). Metal salts or metal compds. of the diazo compds. may be used for producing different tones. Various examples are given among which is the use of Cd and Sn compds. Cf. C. A. 23, 1832.

Photographic emulsions. I. G. FARBENIND. A.-G. Fr. 33,682, June 15, 1927. Addn. to 619,077. Dissocn. products of proteins obtained by electrodialysis are added to gelatin used for light-sensitive emulsions. Cf. C. A. 23, 1832.

Photographic reproductions. MME. ALBIN GUILLOT (née Laure Meifredy). Fr. 647,137, May 31, 1927. Beneath a layer of gelatin or the like sensitized with dichromate, etc., a layer of a substance such as Au or other precious metal is used to give color effects through the sensitized layer.

Photomechanical reproduction. THEODOR DITTMAN. Ger. 471,691, Sept. 30, 1927. Addn. to Ger. 457,654. First a half-tone negative together with a single-tone negative, and then a scale negative, are copied on the etching plate. The order may be reversed.

Desensitizing photographic layers. I. G. FARBENIND. A.-G. (Bruno Wendt, inventor). Ger. 472,095, Feb. 4, 1928. Small amts. of water-sol. derivs. of anthraquinone and phenanthraquinone are used to desensitize photographic layers, particularly layers of panchromatic Ag halide emulsion. The reagents may be applied before development or added to the developing soln. The use of Na 1-nitroanthraquinone-2-

carboxylate, alizarine direct blue B, anthraquinone violet and Na 2-anthraquinone sulfonate is described.

Desensitizing photographic layers. I. G. FARBENIND. A.-G. Ger. 472,096, July 25, 1926. Solns. of 1,3-, 2,4-, or 2,6-diaminophenazonium salts or their substitution products are used. The reagents may be applied before development, or the layers may be developed for a short time in a soln. to which the desensitizing agent has been added, and the development then completed in yellow or orange-red light.

Photographic plates. I. G. FARBENIND. A.-G. (Alfred Miller and Hans Zepter, inventors). Ger. 472,115, April 9, 1927. Halation effects are avoided by coating the glass, on the side away from the emulsion and before applying the emulsion, with a mixt. of cellulose derivs., alkali-sol. resins, and dyes, with or without a softening agent. Adhesion of the coating may be promoted by first treating the edges of the glass, or its whole surface, with a thin colorless layer of an alkali-sol. colloid, e. g., with an alc. shellac soln. or an ammoniacal casein soln. The alkali in the developing soln. acts on the coating so that it can be removed in large pieces. Cf. C. A. 22, 2332.

Four-color cinematographic film assembly. JOHN E. THORNTON. U. S. 1,707,825, April 2.

Photographic films and prints. KALLE & Co. A.-G. Fr. 647,273, Nov. 12, 1927. Prints, films, etc., contg. diazo compds. are made with Ti salts. Thus, a cellulose film is impregnated with an aq. soln. of Na 2,1-diazonaphthol-4-sulfonate, phloroglucinol and titanic oxalate of K. A neutral dark brown tone is obtained after exposure to light through a positive and development with NH_3 .

Light-sensitive papers. LOUIS LIBMANN. Fr. 647,547, Jan. 21, 1928. Leucosulf ethers of vat dyes, commonly called "indigosol," are used for the prepn. of light-sensitive papers, by dissolving them in warm water and coating them on the paper. When exposed to light and washed with water they give unalterable heliographs.

6—INORGANIC CHEMISTRY

A. R. MIDDLETON

Germanium. XXVII. Germanium dichloride. L. M. DENNIS AND H. L. HUNTER. Cornell Univ. *J. Am. Chem. Soc.* 51, 1151-4 (1929).— GeCl_2 was prepd. by passing GeCl_4 over heated metallic Ge, and a number of its properties were studied. T. H. C.

Beryllium and its chloride. M. J. M. SCHMIDT. *Science ind.* 13, 110 (1929).—Two methods have been studied for the production of BeCl_2 from which metallic Be is obtained. The first method involves the reaction of Cl and C on BeO, while the second utilizes the reaction between BeO and COCl_2 . BeCl_2 sublimes at about 450° . The following binary systems were studied in an attempt to find a mixt. which can be fused without decompn. or sublimation. BeCl_2 -NaCl (mixts. do not show much volatilization of BeCl_2 ; the eutectic fuses at about 215°); BeCl_2 -LiCl (eutectic fuses at 300°); BeCl_2 -AgCl (eutectic fuses at 235°); BeCl_2 -BaCl $_2$ (eutectic fuses at 372°); BeCl_2 -CaCl $_2$; BeCl_2 -MgCl $_2$; BeCl_2 -ZnCl $_2$; BeCl_2 -PbCl $_2$; BeCl_2 -TiCl $_3$; BeCl_2 -CdCl $_2$. The latter systems apparently show no eutectics. BeCl_2 is decomposed in water soln. but not in certain org. solvents. S. repeated the work of Debray by displacing Be from its chloride by Na and obtained a powder contg. 81% Be. Li gave a product contg. 71% Be. S. also prepd. Be by electrolysis of fused BeCl_2 . Another chloride of a metal was added to increase the elec. cond., to facilitate fusion, and to diminish volatilization. LiCl was found most useful for this purpose since the elec. resistance is low for mixts. rich in LiCl. A porcelain crucible with electrodes of iron and Acheson graphite was used for the electrolysis. At 2000° BeO can be reduced by carbon but the metal is rapidly re-oxidized by contact with air. The method giving the best results of any studied by S. was the electrolysis of a mixt. of fluorides of Be and Ba, with an anode of graphite as the contg. cylinder and a cathode of iron, cooled internally by cold water. The potential was 70 v. and the current was 50 amps. The electrolysis proper started when the temp. reached 1350° . A fluoride of carbon is formed and this is very harmful to the operator of the electrolysis cell. A Be metal of 99.5 to 99.8% purity was obtained. The metal may be tempered; it resists oxidation by air, and may be welded. A. J. MONACK

The preparation of some metallic chromates. SAMUEL H. C. BRIGGS. *J. Chem. Soc.* 1929, 242-5.—B. has repeated his previous prepn. of ZnCrO_4 (cf. C. A. 2, 955; 4, 882) to meet criticisms of Britton (cf. C. A. 20, 1163). Normal chromates of Cr, Co and Cd were also prepd. by the action of Na_2CrO_4 on an excess of concd. solns. of the corresponding

In addn., the following compds. were prepd.: 9ZrO_2 .-

$5\text{CrO}_3 \cdot 12\text{H}_2\text{O}$; $3\text{Al}_2\text{O}_3 \cdot 2\text{CrO}_3 \cdot 6\text{H}_2\text{O}$; $2\text{Fe}_2\text{O}_3 \cdot 4\text{CrO}_3 \cdot \text{H}_2\text{O}$; $3\text{Sb}_2\text{O}_3 \cdot 2\text{CrO}_3$; $2\text{Sb}_2\text{O}_3 \cdot \text{Cr}_2\text{O}_3$; and $3\text{Bi}_2\text{O}_3 \cdot 2\text{Cr}_2\text{O}_3$.

T. H. CHILTON

A practical method of preparation of sodium hypobromite reagent. O. CHARRO ARIAS. *Anales soc. españ. fis. quim.* 26, 446-9(1928).—Detn. of urea by the hypobromite method has been supplanted by microchem. methods on account of the instability of the hypobromite soln., but this can be prepd. by adding to 5.5 cc. of a soln. contg. 6 g. NaBrO_2 and 20.5 g. NaBr per 100 cc. H_2O 1 cc. of concd. HCl , shaking, letting stand several mins., adding 3.5 cc. of 30% NaOH , giving 10 cc. of reagent, the amt. required for the usual test on 2.5 cc. of urine. The accuracy of the results obtained with this reagent was checked by comparative tests.

E. M. SYMMES

The acidic properties of concentrated solutions of zinc chloride. S. A. VOZNESEN, SKII AND T. A. STRATONOVA. *J. Russ. Phys.-Chem. Soc.* 60, 771-82(1928).—Concd. solns. of ZnCl_2 react acid until dild. below 3-4 N . The acidic properties thus are not due to hydrolysis, since the latter increases on dildn. The $v. m. f.$ between aq. and non aq. solns. of ZnCl_2 changes in sign when the concn. is raised, and in very concd. solns. reaches values which are characteristic for acid chains. This suggests to V. and S. the existence of "aquo acids" $[\text{ZnCl}_2(\text{OH})]\text{H}$ and $[\text{ZnCl}_2(\text{OH})_2]\text{H}_2$. The effect of concd. ZnCl_2 on Landolt's reaction was next investigated. The concns. of HIO_3 and NaHSO_4 were so chosen that the reaction velocity was proportional to $[\text{H-ion}]^2$. The effect of viscosity was experimentally detd. from the reaction velocities in H_2O -glycerol mixts. of const. ρ_H . The reaction time in AcONa buffers of known ρ_H was also measured. The ρ_H of concd. ZnCl_2 solns. was calcd. from the reaction velocities and the above data; the ratio of the concn. of H ion to that of ZnCl_2 decreased with the latter. The reaction velocity also decreased with the concn. of ZnCl_2 in the presence of AcONa buffer. V. and S. conclude that $[\text{ZnCl}_2(\text{OH})_2]\text{H}_2$ hinders the reaction, while the $[\text{ZnCl}_2(\text{OH})]\text{H}$ ion exerts a favorable influence. KCl , CaCl_2 , MnCl_2 , LiCl and MgCl_2 increase the velocity in proportion to their concn. AlCl_3 in all concns. causes a great retard. CdCl_2 , $\text{Cd}(\text{NO}_3)_2$ and CdSO_4 retard the reaction when added in small amts., and accelerate it in large concns. The retarding action is probably due to complex formation by Cl^- ion and free I .

B. SOVENKOFF

Reaction of water on calcium aluminates. LANSING S. WELLS. *J. Res.* 33, 951-1006(1928). The mechanism of the reaction of H_2O with $\text{CaO} \cdot \text{Al}_2\text{O}_3$, $3\text{CaO} \cdot 3\text{Al}_2\text{O}_3$, $5\text{CaO} \cdot 3\text{Al}_2\text{O}_3$, and $3\text{CaO} \cdot \text{Al}_2\text{O}_3$ is discussed. Addn. of H_2O to $3\text{CaO} \cdot \text{Al}_2\text{O}_3$ produces a vigorous reaction and changes in compn. of the resulting aq. solns. could not be followed; the setting is probably due to the formation of hydrated tricalcium aluminate. The mechanism of the reactions of the other aluminates could be studied. During the early periods of the reaction CaO and Al_2O_3 in each case passed into $\text{Ca}(\text{OH})_2$ as the calcium salt of monobasic aluminic acid, the concn. of the aluminate form d. depending upon the compn. of the anhyd. aluminate or cement from which it was formed and upon the time of reaction. These monocalcium aluminate solns. are metastable and decomposed with pptn. of a portion of the CaO and Al_2O_3 . There was an increase in the molgr ratio of CaO to Al_2O_3 remaining in the soln. after pptn. Identical changes in the metastable solns. occurred when filtered from the reaction mixts. As equl. was approached, chem. analyses and microscopic exams. indicated that hydrated AlO and hydrated tricalcium aluminate were pptd. from the metastable solns. The constitution of the aluminates in soln. is reviewed with reference to previous investigations. The conclusion of Slade, Blum and Heyrovsky that aluminic acid is a relatively strong monobasic acid is confirmed. Changes in the aluminate solns. resulting from increased concns. of $\text{Ca}(\text{OH})_2$ were investigated. As the concn. of $\text{Ca}(\text{OH})_2$ is increased, increasing proportions of the total Al_2O_3 are pptd., until at a ρ_H of 12.0 or above the Al_2O_3 is completely pptd. Some CaO is pptd. with the Al_2O_3 . An aluminate of the compn. $4\text{CaO} \cdot \text{Al}_2\text{O}_3 \cdot 12\text{H}_2\text{O}$ seems to be formed at a ρ_H above 12.0. Changes in the aluminate solns. by the $\text{Ca}(\text{OH})_2$ liberated by the hydrolysis of tricalcium silicate are similar to those above. The hydrolysis of β -dicalcium silicate seems to be inhibited by the aluminate soln. The electrometric titration of AlCl_3 with $\text{Ca}(\text{OH})_2$ was made. AlO is completely pptd. as the hydruide between ρ_H 6.0 and 7.5; appreciable solution of the $\text{Al}(\text{OH})_3$ occurs when the ρ_H is greater than 9.0; $\text{Al}(\text{OH})_3$ redissolves completely at ρ_H 10.9; at higher alkalinities a calcium chloroaluminate is formed, its compn. approaching $3\text{CaO} \cdot \text{Al}_2\text{O}_3 \cdot \text{CaCl}_2 \cdot 10\text{H}_2\text{O}$ if the concn. of CaCl_2 exceeds 3%. The optical properties of this compd. were detd. and show $n = 1.550 \pm 0.003$ and $\epsilon = 1.51 \pm 0.003$. The crystals were thin uniaxial negative hexagonal plates. Ba chloroaluminate appears to be more sol. than Ca chloroaluminate. NH_4Cl and MgCl_2 both decompose Ca aluminate solns. with pptn. of $\text{Al}(\text{OH})_3$ by the NH_4Cl and formation of a mixt. of AlO and $\text{Mg}(\text{OH})_2$ by the MgCl_2 .

A. J. MONACK

The reaction between ferric sulfate solution and cuprous sulfide. LAWRENCE WHITBY. Chem. Res. Lab., Teddington, Eng. *J. Chem. Soc.* 1929, 60-1.— Cu_2S was prepd. by exposing Cu foil to H_2S . When small amts. of Cu_2S were immersed for 15 mins. at room temp. in 10 cc. of 40% $\text{Fe}_2(\text{SO}_4)_3$, the resulting reaction could be represented by the equation $\text{Cu}_2\text{S} + \text{Fe}_2(\text{SO}_4)_3 = \text{CuS} + \text{CuSO}_4 + 2\text{FeSO}_4$. The validity of this expression was established by analysis of the solid residue (CuS) and also by measurement of the amts. of $\text{Fe}_2(\text{SO}_4)_3$ reduced by known wts. of Cu_2S . Prolonged exposure caused further oxidation; $\text{CuS} + \text{Fe}_2(\text{SO}_4)_3 = \text{CuSO}_4 + 2\text{FeSO}_4 + \text{S}$. At 60–80°, the oxidation is so rapid that the reaction $\text{Cu}_2\text{S} + 2\text{Fe}_2(\text{SO}_4)_3 = 2\text{CuSO}_4 + 4\text{FeSO}_4 + \text{S}$ is a correct representation of the phenomenon. R. L. DODGE

The reaction between nitrous acid and hydrogen sulfide. LANCELOT S. BAGSTER. Univ. of Queensland, Brisbane. *J. Chem. Soc.* 1928, 2631-43. This reaction was studied by slowly passing measured vols. of NO into a vessel contg. H_2S in soln. and O_2 . The reaction products vary with the relative concns. When HNO_2 is in excess, NO and smaller quantities of N_2O are the principal reduction products. When H_2S is in excess, however, hydrogenated products are formed almost entirely, NH_3 and NH_4OH in acid soln., and chiefly NH_3 with a smaller amt. of NH_4OH in aq. soln. Except when HNO_2 is present in quantity and in excess, the H_2S concn. being small, H_2S is oxidized almost completely to S, with a relatively small amt. of SO_2 . Even when a rather concd. HNO_2 soln. is added to a fairly concd. H_2S soln., S predominates. The reaction between H_2S and NH_4NO_2 was also investigated. When H_2S was passed continuously through an approx. 0.05 N NH_4NO_2 soln., there was gradual but not complete reduction of nitrite to NH_3 , about 50% being reduced in 24 hrs. The low rate of oxidation compared to the high rate in the case of free HNO_2 suggests that the free acid, produced here by hydrolysis, is the active agent rather than the nitrite ion. The decrease in the rate of reaction on the addn. of $(\text{NH}_4)_2\text{S}$ and the increase on the addn. of $(\text{NH}_4)_2\text{S}_2$ or on the formation of S are ascribed to the influence of the polysulfide ion, which effects an increase in the concn. of the reducing ion. The following simple reactions are proposed, (1) and (2) for appreciable HNO_2 concn., (3) and (4) for small HNO_2 concn. and considerable H_2S concn.: (1) $3\text{HNO}_2 + \text{S}^{2-} \rightarrow 3\text{HNO} + \text{SO}_3^{2-} (+ 3\text{H}_2\text{O})$; (2) $\text{HNO}_2 + \text{S}^{2-} \rightarrow \text{HNO} + \text{S}^{2-} (+ \text{H}_2\text{O})$; (3) $\text{HNO}_2 + 2\text{S}^{2-} \rightarrow \text{NH}_4\text{OH} + (\text{H}_2\text{O}) + 2\text{S}$; (4) $\text{HNO}_2 + 3\text{S}^{2-} \rightarrow \text{NH}_3 + (2\text{H}_2\text{O}) + 3\text{S}$. As secondary products, NO may be formed by the reaction of HNO and HNO_2 , and N_2O and N_2 by the direct decompn. of HNO, or as secondary products of reaction (3). RUBY K. WORNER

Hypophosphoric acid. FRIEDRICH VOGEL. Univ. Berlin. *Z. anorg. Chem.* 42, 263(1929).—Replying to Speter's statement (*Z. anorg. Chem.* 41, 693; cf. *C. A.* 22, 198) that hypophosphoric acid is formed from the action of chloride of lime upon red P, and that a new form of P arises differing in its action toward oxidizing agents, it is shown that KMnO_4 in strongly alk. solns. changes P to $\text{H}_2\text{P}_2\text{O}_6$, and that H_2O_2 in alk. soln. or alone also oxidizes red P to $\text{H}_2\text{P}_2\text{O}_6$, and H_2PO_3^- . Exptl. results are given for detns. with $\text{Ba}(\text{PO}_3)_2$ obtained from given amts. of P used. No evidence of a new form of P was found. W. C. EBAUGH

Sulfurous acid and its salts. VI. Auto-decomposition of aqueous bisulfite solutions. F. FOERSTER AND E. HAUFFE. Tech. Hochschule, Dresden. *Z. anorg. allgem. Chem.* 177, 17-41(1929); cf. *C. A.* 21, 1420. It was shown earlier that bisulfite solns. decompd. as indicated by the equation $3\text{HSO}_3^- \rightarrow 2\text{SO}_3^{2-} + \text{H}^+ + \text{S} + \text{H}_2\text{O}$, and that the reaction occurred in 2 sharply defined phases, viz., (a) sulfates, thiosulfates and polythionates were formed, with almost complete disappearance of bisulfites, and (b) thiosulfates and polythionates were transformed into sulfates and free S with the re-formation of sulfites. The first phase was hastened catalytically by Se, which could be recovered quantitatively after the reaction. Exptl. detns. were made upon solns. of NaHSO_3 contained in glass flasks provided with suitable attachments for admitting and removing gases, measuring pressure, etc., at known temps., and for measured intervals of time. The decompn. of NaHSO_3 , the formation of sulfate, polythionate, acidity, amt. of Se and S sepd. and other necessary factors were detd. and the results presented in numerous tables and graphs. Conclusions are: (1) The auto-decompn. of bisulfite solns., whose velocity is known, is increased by the presence of Se and proceeds with increasing speed even autocatalytically. (2) This reaction yields at first $4\text{HSO}_3^- \rightarrow \text{SO}_4^{2-} + \text{S}_2\text{O}_4^{2-} + 2\text{H}_2\text{O}$. (3) The previously accepted idea that sulfate and tetrathionate were the decompn. products has proved to be erroneous. (4) The slower the reaction proceeds, the more time there is for the trithionate to change thus: $\text{S}_2\text{O}_4^{2-} + \text{H}_2\text{O} \rightleftharpoons \text{SO}_4^{2-} + \text{S}_2\text{O}_3^{2-} + 2\text{H}^+$. (5) The H ions, whose concn. increases, because of the disappearance of HSO_3^- , more rapidly than the acidity titrate-

able with methyl orange as indicator, are responsible for the autocatalytic course of the bisulfite decompn. (6) This effect depends upon the fact that the selenodithionate (formed immediately by Se or SeO_2 in a bisulfite soln.) is decompd. with increased velocity by H ions, thus: $\text{SeS}_2\text{O}_6^{--} + \text{H}_2\text{O} \longrightarrow \text{SO}_4^{--} + \text{SeSO}_3^{--} + 2\text{H}^+$. (7) SeSO_3^{--} reacts immediately with bisulfite solns. to form selenodithionate and trithionate presumably thus: (a) $\text{SeSO}_3^{--} + 2\text{H}^+ \longrightarrow \text{SeO} + \text{SO} + \text{H}_2\text{O}$; (b) $\text{SeO} + 2\text{HSO}_3^{--} \longrightarrow \text{SeS}_2\text{O}_6^{--} + \text{H}_2\text{O}$; (c) $\text{SO} + 2\text{HSO}_3^{--} \longrightarrow \text{S}_2\text{O}_6^{--} + \text{H}_2\text{O}$. (8) In the absence of Se the bisulfite is decompd. very slowly into sulfate and thiosulfate thus: $4\text{HSO}_3^{--} \longrightarrow 2\text{SO}_4^{--} + \text{S}_2\text{O}_6^{--} + 2\text{H}^+ + \text{H}_2\text{O}$. (9) The H ions so formed are responsible for the autocatalytically accelerated reaction velocity. (10) The exhaustive continuation of this process is applicable to the reactions involved even when no Se is present, yet the bisulfite decompn. proceeds with ever increasing velocity. VII. The mutual action of bisulfites and sulfhydrylates. F. FORSTER AND E. KIRCHHEISEN. Tech. Hochschule, Dresden. *Ibid* 42-60.—When H_2S and H_2SO_3 interact solns. of pentathionic and tetrathionic acids are formed, with some free S; and only traces of thiosulfuric and trithionic acids can be found. But if the primary alkali salts are used, i. e., the anions SH^- and SO_3H^- at small H-ion concn., a reaction occurs thus: $2\text{SH}^- + 4\text{SO}_3\text{H}^- \longrightarrow 2\text{SO}_4^{--} + 3\text{H}_2\text{O}$, and only small quantities of by-products are formed. Carefully prep'd solns. of NaSH and NaSO_3H were allowed to react and the formation of thiosulfates, etc., followed in detail. It is shown that (1) pure sulfhydrylate- and bisulfite-solns. mixed in the proportion $1\text{MSH} : 2\text{MSO}_3\text{H}$, at ordinary temps., interact almost instantaneously, yielding thiosulfates in practically theoretical amts., thus: $2\text{MSH} + 4\text{MSO}_3\text{H} \longrightarrow 3\text{M}_2\text{S}_2\text{O}_5 + 3\text{H}_2\text{O}$. (2) Sulfite and S are formed as by-products in the proportion $1\text{S} : 1\text{SO}_3^{--}$. (3) In the presence of bisulfites in quantity exceeding the above ratio, even at ordinary temps., instantaneous reaction occurs with the formation of trithionate and sulfite along with thiosulfate; the quantities of these products increase with increased excess of bisulfites used. (4) The reactions leading to the formation of thiosulfate proceed so extraordinarily rapidly that the effect of a marked excess only appears when the sulfhydrylate soln. is added to the bisulfite soln. When the procedure is reversed only thiosulfate is formed, and the bisulfite used in excess of the proportion $1\text{MSH} : 2\text{MSO}_3\text{H}$ remains unchanged. (5) Theories of the process involved show that the reaction probably proceeds thus: $\text{SO} + 2\text{HSO}_3^{--} \longrightarrow \text{S}_2\text{O}_6^{--} + \text{H}_2\text{O}$. VIII. Remarks on the contribution of H. Bassett and R. G. Durrant. The mutual relations of acids of sulfur. F. FORSTER. Tech. Hochschule, Dresden. *Ibid* 61-70; cf. C. A. 21, 2844. Polemical. Essential agreement as to the facts observed is acknowledged, but their theoretical interpretations are different. W. A. R.

Nitrosylsulfuric acid. II. CYRIL W. H. JONES, WM. J. PRICE AND H. J. BAKER. Warrs. Tech. Coll., Birmingham. *J. Chem. Soc.* 1929, 312-5, cf. C. A. 20, 1411. Nitrosylsulfuric acid (I) was prep'd from chlorosulfonic acid and N_2O_4 giving good evidence for the presence of an hydroxyl group in the structure of I. Attempts were made to prep. nitrosylsulfuric anhydride (II), by: (a) reaction of liquid SO_3 with N_2O_4 , (b) passing NO into liquid SO_3 , (c) distn. of I with P_2O_5 , (d) reaction of N_2O_4 with pyrosulfuric acid and (e) reaction of N_2O_4 with pyrosulfuryl chloride. Methods (a) and (e) gave a compd. considered as II with the compn. $\text{S}_2\text{N}_2\text{O}_6$, to which the structure $\text{O.NO.SO}_2\text{O.SO}_2\text{O.NO}$ is assigned. Methods (b) and (c), and distn. of II gave $\text{S}_2\text{N}_2\text{O}_6$ and $2(\text{2SO}_3\text{N}_2\text{O}_4)\text{SO}_3$ formed from II by absorption of SO_3 . I. H. C.

The equilibrium between water, sodium nitrate, and sodium chloride. A. CHRISTIAN AND E. CORNUC. *Compt. rend.* 188, 628-31 (1929).—Sol. measurements from -24.3° to 121.4° enable a phase diagram to be constructed showing the relationships between water, sodium nitrate, sodium chloride and sodium chloride dihydrate.

MALCOLM D. H.

The system: mercuric iodide-potassium iodide-acetone. (MISS M. J. JONES. *Compt. rend.* 188, 635-7 (1929); cf. C. A. 22, 1919.—The method of Schreiner is applied to the study of the solid-liquid equil. in the system HgI_2 , KI and acetone at 34° . The salt $2\text{HgI}_2 \cdot 3\text{KI}$ which exists at 56° is not found at 34° , but is replaced by a new salt $\text{HgI}_2 \cdot \text{KI} \cdot \frac{1}{2}\text{C}_2\text{H}_5\text{O}$.

MALCOLM D. H.

Attempted resolution of triethylenediaminenickel chloride. WILLIAM J. BUCKNALL AND WILLIAM WARWICK. Univ. of Birmingham, Edgbaston. *J. Chem. Soc.* 1929, 2739-42.—For the resolution, triethylenediaminenickel tartrate and triethylenediaminenickel *d*-camphorsulfonate were used, but with negative results. It appears either that the rotatory power of the active Ni triethylenediamine is very small or that the racemization in soln. is extremely rapid. Attempts to prep. the chloride tartrate by saturating the complex chloride with one equiv. of Ag tartrate result in a mixture of the normal tartrate and the original chloride. The tartrate, $[\text{Ni}(\text{en})_2][\text{C}_6\text{H}_5\text{O}_2\text{SO}_2]\text{H}_2\text{O}$.

was prepd. by this method, *vis.*, triturating the chloride soln. with the theoretical amt. of Ag tartrate, repeatedly extg. with hot H₂O and evapg. the soln. Two tartrates appeared to be present, one cryst. and one a gel. *Triethylenediaminenickel d-camphorsulfonate*, [Ni(en)₃](C₁₀H₁₆O₂S)₂·H₂O, was prepd. by adding Ag *d*-camphorsulfonate soln. in small quantities to a soln. of recrystd. triethylenediaminenickel chloride until the addn. of one drop caused no more pptn. of AgCl. RUBY K. WORTNER

A cobaltic mono-amine. CLÉMENT DUVAL. *Compt. rend.* 188, 176(1929).—Na cobaltiammonio-borate, [Co(BO₂)₃·NH₃]₂Na₂, has been prepd.: it is the first known compd. of the type [CoNH₃·X]₂M₂. Its method of prepn. is: heat 10 g. [Co(NO₃)₃·(NH₃)₃] for 15 mins. at 45° with 50 cc. H₂O and 7.5 g. Na metaborate. The liquid becomes purple, and NH₃ is evolved. Cooling causes a purplish gray ppt., little sol. in H₂O (about 1 part in 3000). Wash with EtOH and then with Et₂O. A. L. H.

Cobalt allylamines: a supposed coordination number of eight for cobalt. WILLIAM R. BUCKNALL AND WILLIAM WARDLAW. Univ. of Birmingham, Edgbaston. *J. Chem. Soc.* 1928, 2648-54.—A reinvestigation has been made of the compd. for which Pieroni

(cf. *C. A.* 15, 3036-7) deduced the formula $\left[\text{Co} \begin{array}{c} 6\text{C}_3\text{H}_7\text{NH}_2 \\ 2\text{O}_2 \end{array} \right] \text{Cl}_2 \cdot \text{H}_2\text{O}_2$, thus assigning

to Co a covalency of 8. When N₂ is drawn through a satd. soln. of CoCl₂ in abs. alc., purplish red, needle-like crystals sep. on cooling. These crystals are very deliquescent and unstable, give a blue soln. with alc., and decompose in H₂O with the pptn. of CoCl₂. P. assigned them the formula CoCl₂·3C₃H₇NH₂. When dry air is drawn through the reaction flask contg. the crystals in contact with the methanol, the color from purplish red to blue.

It would agree with the data of P. and P. and by Pieroni, but differs markedly. Whereas the data of P. and P. indicate a ratio of Co:Cl = 1:3, the new figures show a ratio of 2:2.982. New formulations,

are proposed which assign to Co valencies of 3 and 4 and covalency of 6, which is in agreement with Sidgwick's rule. From analytical data and detns. of the mol. wt. and the mol. cond., the first formula seems the more probable. Red crystals of *hexaallylamine peroxodihydroxodicobalt trinitrate*, $\left[3\text{C}_3\text{H}_7\text{NH}_2 \cdot \text{Co} \begin{array}{c} \text{O}_2 \\ \text{OH} \end{array} \text{Co} \cdot 3\text{C}_3\text{H}_7\text{NH}_2 \right] (\text{NO}_3)_3$, are formed by

the action of HNO₃ or a soln. of any metallic nitrate on the complex chloride. This compd. liberates HNO₃ when moistened with H₂SO₄, is slightly sol. in cold H₂O, hydrolyzes with pptn. of the hydroxide on standing or warming, and evolves allylamine on warming with NaOH. When distd. with NaOH and Devarda's alloy, the nitrate groups are reduced to NH₃. When either of the complex salts is treated with concd. HCl, a dark green, insol. substance is formed which on warming dissolves to a bluish green soln. of CoCl₂ and allylamine chloride. H₂SO₄ decomposes the complex ion, forming CoSO₄. With AgNO₃, the complex chloride gives an immediate ppt. of AgCl, together with a red ppt. in concd. soln. of the complex nitrate. (NH₄)₂S produces an immediate ppt. of CoS. When the complex salts are warmed with KI soln., I₂ is liberated, but no similar oxidation could be detected with KBr. The study is being extended to the products of atm. oxidation of alc. solns. of Co salts in the presence of various other amines. RUBY K. WORTNER

Chromites and ferrites of nickel and cobalt. (MILLÉ) SUZANNE VEIL. *Compt. rend.* 188, 330-2(1929).—The chromites and ferrites can be considered as formed from 2 oxides, one tervalent and the other bivalent. Hence they may be classed as spinels. Equimolar solutions of the sulfates were pptd. in the cold by soda, dried in the cold, calcined, and the coefficient of magnetization measured. This coefficient has already been shown to be characteristic. On adding NiSO₄ or CoSO₄ to either Cr₂(SO₄)₃ or Fe₂(SO₄)₃, the curve of α —tion of the calcined anhydrides reaches a max. and then falls to the value of the added pure sulfate. The max. corresponds to ferrite and chromite of Ni and Co. The magnetization values obtained are about 1000 times those of the pure constituents. Hence the presence of Fe in Ni or Co is important,

and reciprocally. These facts also explain the variations in the magnetic coefficients of different mineralogical specimens.

S. L. B. ETHERTON

A new kind of complex platinum compounds. Tervalent and quinquivalent platinum. PRAFULLA CHANDRA RAY AND KSHITISH CHANDRA BOSE RAY. *Z. anorg. allgem. Chem.* 178, 329-36(1929).—The methods of prepn. and compn. are given for 13 of a series of 14 sulfone derivs. of $[(C_2H_5)_2S_2PtCl]_n$ with NH_3 , alkyl and aryl amines, and piperidine. Mediating S atoms seem to serve as binding agents, making it possible for as many as 13 Pt atoms to occur in one mol. Pt in the mother substance has a valence of 5 but in the derivs. it has a valence of 3. Some contain a single quinquivalent atom. All the remaining valences of Pt after the Cl valence is subtracted must amount to a multiple of 4, so Pt never has an even valence in this series. The compds. contg. NH_3 , Cl, Pt_2Cl and Pt_3Cl all contain tervalent Pt and the remaining valences amount to a multiple of 4, but in compds. contg. 5 atoms of Pt, one must be quinquivalent. Graphic formulas are given for 2 such compds.

MARY E. LEAR

Studies on the physical and chemical properties of the cyanoplatinites. I. The hydrates of lithium cyanoplatinite. FRANK E. E. GERMAN AND O. B. MUENCH. *J. Phys. Chem.* 33, 415-23(1929). Methods of prepn. of cyanoplatinites and a review of the work on $Li_2Pt(CN)_4$ are given. Pure $Li_2Pt(CN)_4$ was prepd. and its hydrates were studied by a vapor-tension method. Canary-yellow anhyd. $Li_2Pt(CN)_4$ is formed at 25° with water vapor pressures below 1.02 mm. Hg. The only hydrate is $Li_2Pt(CN)_4 \cdot 4H_2O$; the others reported do not exist. $Li_2Pt(CN)_4 \cdot 4H_2O$ is variously colored, depending on method of prepn. and treatment. A tan modification is found at 25° by exposing the anhyd. salt to a pressure of water vapor greater than 1.02 mm. Hg. A blue modification is formed from the tan salt by exposing the latter to bright sunlight, ultra-violet light or water vapor at low pressures but above 1.02 mm. High water vapor pressures inhibit this change but it is catalyzed by hydrogen and cyanide ion. The grass-green form crystallizes in needles from water solns. The equil. vapor pressure of a satd. water soln. of $Li_2Pt(CN)_4 \cdot 4H_2O$ at 25° is 14.14 mm. Hg. C. W. W.

Oxidation with fluorine. XI. Action of fluorine on solutions of salts of thallium, manganese, copper and lead. FR. FICHTER AND ERNST BRUNNER. *Helv. Chim. Acta* 12, 214-21(1929). cf. C. A. 21, 2854. Tl_2SO_4 in neutral aq. soln. was treated with gaseous F_2 and reacted according to the equation

The presence of free H_2SO_4 aids the reaction by reducing hydrolysis. Tl_2SO_4 was dissolved in 3 N H_2SO_4 , cooled with ice and treated with gaseous F_2 and cryst. TlH was obtained. $TlNO_3$ soln. was also oxidized with F_2 . Manganous phosphate was oxidized to manganic phosphate. The action of F_2 on Cu and Pb salts is explained. Cu_2O can be obtained by the action of F_2 . Neutral or acid Pb soln. give only PbF_2 but alk. plumbite solns. treated with F_2 give PbO_2 . R. H.

The oxidation of cobalt sulfate and potassium cobalt oxalate with ozone. ERNST BRUNNER. *Helv. Chim. Acta* 12, 218-13(1929). A discussion is given of the conflicting theories on the oxidation of $CoSO_4$ to $Co_2(SO_4)_3$. A new method is for the prepn. of $Co_2(SO_4)_3$ by the action of ozonized O_2 on $CoSO_4$ in H_2SO_4 and is also given a new method for the prepn. of K cobaltic oxalate by the action of O_3 on K cobaltous oxalate. R. H.

7.—ANALYTICAL CHEMISTRY

W. T. HALL

Chart of indicators useful for pH measurements. CLARKE E. DAVIS and HENRY M. SALISBURY. *Ind. Eng. Chem., Anal. Ed.* 1, 92(1929).—The intervals of color change for 15 indicators are plotted all on the same scale of pH values so that at a glance one can at a glance which indicators are useful for any given case. W. T. H.

Cupric oxide as a standard in iodometry. T. F. BUEHNER AND C. MORGAN MASON. *Univ. Arizona. Ind. Eng. Chem., Anal. Ed.* 1, 68-70(1929).—Several samples of CuO were studied with respect to availability as standards in iodometry. The samples tested were 99.8-99.9 pure but more uniform than some samples of Cu foil. If, therefore, the Cu value of the well-mixed oxide, which has been ignited in O_2 at 400° and dried very carefully, is analyzed electrolytically, it will serve as an excellent standard.

If the H_2SO_4 soln. of the oxide is evapd. to dryness and then taken up in water, treatment with NH_4OH and HAcO is superfluous. In fact, the reduction of the Cu^{++} by KI succeeds in 0.2 N H_2SO_4 soln.

• **Experimental studies on quantitative emission spectral analysis. I. The basic principles of quantitative spectral analysis.** HILDE THURNWALD. *Tech. Hochschule Prague. Z. anal. Chem.* 76, 260-1 (1929). The principles upon which quant. spectral measurements depend are described critically and the necessary app. is shown. The various factors influencing the intensity of the spectral lines are discussed and some exptl. results given. A bibliography shows 16 papers written since 1880.

W. T. H.

The determination of alkali in seepage water (in oil wells). K. L. MALYAROV. *J. Russ. Phys.-Chem. Soc.* 60, 829-34 (1928).—Treat 100 cc. of the water with a slight excess of BaCl_2 soln. at 100° . Filter, evap. the filtrate in a Pt dish to dryness together with 6-15 g. of oxalic acid. Heat to dull redness, cool, dissolve in hot water, filter and titrate with 0.1-0.5 N HCl . The analysis is based on the assumption that the residue contains Na_2CO_3 .

B. SOYENKOFF

Determination and separation of rare metals from other metals. XIII. Testing gravimetric methods for determining vanadium and comparison with two other methods for its determination. LUDWIG MOSER AND OSKAR BRANDL. *Monatsh.* 51, 169-80 (1929); cf. *C. A.* 23, 1838. For the detection of V the most characteristic reaction appears to be the test with 3-6% H_2O in strong H_2SO_4 soln. The coloration is probably due to $(\text{VO})_2(\text{SO}_4)_3$ rather than to HVO_4 , as is commonly assumed. The test with phosphotungstic acid is equally delicate. The thiocyanate test is less delicate and the test with tannin is good and suitable for the detn. of small quantities of V. The tests with diphenylamine and with strychnine are less satisfactory. The detn. of V as NH_4VO_3 is very accurate; if low results are obtained it is usually due to slight volatility of V_2O_5 when heated with NH_4Cl . After washing the ppt. with cold, satd. NH_4Cl , therefore, the dried ppt. should be heated for some time at about 150° to volatilize all the NH_4Cl . Final ignition with HNO_3 or NH_4NO_3 is unnecessary if proper pains are taken with the ignition. The detn. of V as AgVO_3 is very easy and accurate. It is also possible to det. V as Ag_3VO_4 if the soln. is kept near the neutral point by the addition of a very little NH_4OH and some NaOAc . In the presence of NaOAc , treatment with AgNO_3 gives a ppt. consisting largely of Ag_3VO_4 ; if the soln. is cold. On heating with excess AgNO_3 present, the ppt. changes to AgVO_3 . To det. V as AgVO_3 add 3 g. of NaOAc and 0.5 cc. of concd. NH_4OH to the neutral soln. contg. 0.2 g. V_2O_5 in 200 cc. Add an excess of AgNO_3 and heat to boiling. After standing 0.5 hr. on the water bath, add more AgNO_3 to see if the pptn. is complete. Filter, wash with hot water, dry and weigh. It is also possible to det. V accurately as $\text{Pb}_2\text{V}_2\text{O}_7$. Expts. indicate that the primary form of the ppt. is $\text{Pb}_2\text{V}_2\text{O}_7$; but in the presence of excess Pb and sinking acidity, this changes to $\text{Pb}_3\text{V}_2\text{O}_7$. To the neutral soln. contg. 0.2 g. of V_2O_5 in 200 cc., add $\text{Pb}(\text{NO}_3)_2$ until the ppt. begins to coagulate. Then add $\frac{1}{4}$ as much more of the reagent and enough HNO_3 just to dissolve the ppt. Now add 0.1 N NaOH until the soln. remains barely acid. Add 0.1 g. of KBrO_3 and while boiling the soln. introduce a stream of air to prevent bumping and at intervals of 10 mins. add 2 cc. portions of a soln. contg. 12 g. KBr and 3.37 g. KBrO_3 per 100 cc., using 10-16 cc. of this mixt. Boil 2 hrs. longer, filter, wash, dry at 110° and weigh as $\text{Pb}_2\text{V}_2\text{O}_7$. The detn. of V as V_2O_5 after pptn. as Hg_2VO_4 has been often recommended. Expts. show, however, that it is difficult to obtain a ppt. of definite compn. and definite soly. The presence of HgO appears to be necessary and the addn. of H_2O_2 appears to be favorable. The following modified procedure is suggested. To the hot, neutral or slightly acid (with HNO_3) soln., which must be free from NH_4 salt, add 3 cc. of 10% H_2O_2 and an excess of HgNO_3 soln. (40 cc. of the hot, satd. soln. for 0.1 g. of V_2O_5). Boil 0.5 hr., filter, wash with cold water, ignite and weigh as V_2O_5 . XIV. Separation of beryllium from the alkaline earth metals of the ammonium sulfide and arsenic groups. LUDWIG MOSER AND FERDINAND LUT. *Ibid.* 181-9. —This, the last of several papers, concludes the survey of methods for the complete sepn. of Be from other cations. To accomplish such sepn. one of the best ways is to make the accompanying ion form a complex with

tannin; in this way Be can be sepd. from Al, Fe, Cr, Ti, Zr, Th and W. Another possibility depends upon the hydrolysis of the Be salt; thus Be can be sepd. from Mo by the addn. of NH_4NO_3 to the dil. aq. soln. The purpose of the present paper is to generalize and apply these 2 methods to various concrete cases. *Seprn. of Be from alk. earths and Mg.*—Except with Ba, it is best to ppt. $\text{Be}(\text{OH})_2$ by hydrolysis, adding NH_4NO_3 to keep the H concn. low and removing the liberated HNO_3 as Me ester. With Ba, this method fails because com. NH_4NO_3 is likely to contain a little sulfate. In this case, it is best to ppt. BaSO_4 by the "extreme diln." method and ppt. Be in the filtrate with tannin. *Seprn. of Be from the monoxides and from Ti.*—Treatment with NH_4NO_3 and MeOH to cause pptn. of $\text{Be}(\text{OH})_2$ serves to sep. Be from all the cations of this group. With Zn, however, it is also possible to ppt. ZnS first from dil. sulfosalicylic acid solns. in the presence of NH_4OAc . With Cd also, it is permissible to ppt. CdS from dil. H_2SO_4 soln. With Ni, the Ni salt of dimethylglyoxime can be obtained if tartaric or sulfosalicylic acid is present to prevent pptn. of $\text{Be}(\text{OH})_2$, but the NH_4NO_3 method is easier. With Mn, it is well to ppt. MnO_2 from dil. H_2SO_4 soln. by adding $(\text{NH}_4)_2\text{S}_2\text{O}_8$ and heating. With Ti, it is possible to ppt. Ti first as Ti_2CrO_7 , but the presence of considerable CrO_3 causes difficulty in the Be detn. *Seprn. of Be from the As group.*—The removal of As as insol. sulfide or as volatile AsCl_3 serves for the seprn. of Be from As. Pptn. of Sb as Sb_2S_3 serves for the seprn. of Be from Sb. With Sn, H_2S pptn. or formation of metastannic acid does not work out well. The following procedure which depends upon the formation of an adsorption compd. of quadrivalent Sn with tannin is excellent. To the clear soln. of the chlorides, strongly acid with HCl, add 5 cc. of 10% tannin soln., 10–20 g. of NH_4OAc and 10–20 g. of NH_4NO_3 . Boil, allow to stand on the water bath 1 hr., filter and wash with hot water contg. a little tannin. If more than 0.2 g. of Sn is present, dissolve the ppt. in HCl and repeat the pptn. A short summary of methods of seprn. when other cations are present is given. With W, the pptn. of this element by tannin is often incomplete. To remove traces of WO_3 from the filtrate add a clear 15% soln. of antipyrine and heat for some time on the water bath. W T H

The confirmatory test for aluminum. RAYMOND GEMMILL, ROBERT BRACKETT AND C. R. McCrosky. Syracuse Univ. *J. Am. Chem. Soc.* 51, 1165(1929) = Parégnan and Solivan (*C. A.* 22, 3859) recently published a modification of the Thénard blue test for Al, using asbestos fiber instead of a filter paper. Similar tests were made at Syracuse prior to this publication. The modified procedure also works well in the Zn test. W T H

Determination of chromium, tungsten, molybdenum, vanadium, manganese and cobalt in highly alloyed steel. H. MENDE. *Chem.-Ztg.* 53, 178-9(1929) = *Ind.* Cr.—Treat 1 g. of metal (0.5 g. if more than 10% of Cr is present) with 25 cc. of concd. H_2SO_4 and 25 cc. of water. If W is present, add at the same time 25 cc. of 20% Na_2HPO_4 soln. Heat till no more gas is evolved and add 20 cc. of 50% $(\text{NH}_4)_2\text{S}_2\text{O}_8$ soln. This accomplishes the oxidation of all carbides. If the Cr content is high, evaporate, adding the persulfate, till the vol. is reduced $\frac{1}{2}$ in order to make the black residue light and flocculent. It may be necessary to dil. with water and repeat this evaporation several times in order to get all of the sample into soln. Then add the persulfate soln. After this addn., dil. with 500 cc. of water, add 5 cc. of 0.2 N AgNO_3 soln. and continue as usual for the persulfate method of detg. Cr, adding more persulfate if necessary to produce the permanganate color. *Detn. of Ni.*—Treat 0.5 g. of metal with concd. HCl, oxidize with HNO_3 and dil. with 3 vols. of hot water. After standing a short time, filter and continue as in the usual dimethylglyoxime method. *Detn. of Co.*—Dissolve 2 g. of steel in concd. HCl and oxidize with HNO_3 in a 500-cc. flask. Add an excess of ZnO suspension in water to ppt. Fe, Cr, V, Mo, Ti, Al, Si, Cu and W. Dil. to the mark, mix and filter off 100 cc. Add 10 cc. of HCl and 40–60 cc. of nitroso- β -naphthol soln. (2 g. of the solid dissolved in 100 cc. of alc.; or 25 cc. of a soln. of 2 g. of the reagent in 50 cc. of AcOH can be used). Filter, wash, ignite and weigh as Co_2O_3 . *Detn. of W.*—If less than 5% of Cr is present, the W can be obtained as WO_3 by treatment with concd. HCl and HNO_3 . The first ppt. should be filtered off and digested with 3 N HCl and KClO_3 . If the steel is rich in Cr, the WO_3 will be black and contain Cr carbide together with some Mo and V. In this case, wash the first ppt. of WO_3 with water contg. NH_4NO_3 and fuse it with soda. Treat the melt with water and some HCl, transfer to a 500-cc. flask and treat with alc. to reduce the Cr. Then add NH_4OH , boil for some time and make up to 500 cc. Filter, take 250 cc. of the filtrate, make neutral to methyl orange with HCl and add 10 cc. of 0.1 N H_2SO_4 . Ppt. the W, V and Mo that are present in the first insol. residue by adding benzidine-HCl. Fuse the ppt. with $\text{K}_2\text{S}_2\text{O}_8$ and treat the melt with cold water and a little HCl. The WO_3 ppt. should now be pure. *Detn. of Mo and V.*—In the filtrate from the WO_3 the Mo can be detd.

as MoO_3 after prior pptn. as MoS_3 by pouring the soln. slowly into boiling KOH soln., filtering, making slightly acid and introducing H_2S under pressure. In the filtrate from the MoS_3 pptn. the V can be detd. as follows: Boil off H_2S , oxidize with Br_2 , boil off excess Br, make slightly ammoniacal and add an aq. soln. of 1 g. MnCl_2 . Filter, dissolve the Mn vanadate ppt. in HNO_3 , evap. 3 times with concd. HCl , then with H_2SO_4 and titrate with KMnO_4 . Or, if desired, the V can be detd. colorimetrically with H_2O_2 . In this case treat 25-50 cc. of ammoniacal filtrate from the $\text{Cr}(\text{OH})_3$ pptn. with 20 cc. of concd. HNO_3 , add 30 cc. of H_3PO_4 and 2 cc. of 3% H_2O_2 . For the Mn detn., it is recommended to dissolve 5 g. of the material in 50 cc. of HNO_3 with a little HF , dil., and ppt. the Fe and Cr with ZnO suspension. Then ppt. the Co with KNO_2 in the filtrate. Filter and treat with 4 g. of urea to remove HNO_2 and finally titrate the Mn with KMnO_4 after adding more ZnO . W. T. H.

The detection of gold and the metals found with crude platinum. SPORCO. Soc. mines d'or Kilo-Moto, Belgian Congo. *Bull. soc. chim. Belg.* 38, 21-4(1929).— SnCl_2 gives characteristic color reactions with the pure chlorides of the following metals: Au, blue-black color or ppt.; Pt, brown; Pd, brick red; Ru, pale yellow; Ir, orange-yellow. It has been shown (with the bead obtained after cupellation) that 0.001 mg. Au can be detected. The method may be used in prospection, but requires a certain practice; an excess of SnCl_2 should be used to eliminate the color due to Fe in the mineral investigated. It is also possible to use this method to detect Pt in refined gold. The order of magnitude of the precious metal content may be estd. from the intensity of the colors: this also requires training. Mo, W, V, Cu or Cr interfere with the reaction, but since Au is generally sought in quartz, this case is rarely met. A. L. H.

The electroanalytic determination of lead. A. V. PAMFILOV AND A. A. BLAGONRAVOVA. Polytechnicum at Ivanovo-Voznesensk. *J. Russ. Phys.-Chem. Soc.* 60, 699-706(1928).—A study of various electrolytic methods confirms the general opinion that anodic disposition of PbO is preferable to cathodic deposition of Pb. B. S.

New method for the rapid determination of mercury. G. SPACU AND J. DICK. Rumanian Univ. at Cluj. *Z. anal. Chem.* 76, 273-7(1929).—If an aq. soln. of Hg^{++} salt is treated with solid $(\text{NH}_4)_2\text{Cr}_2\text{O}_7$ and then pyridine is added as soon as the dichromate has dissolved, a fine, orange yellow ppt. of a complex salt of Hg with dichromate and pyridine is obtained, corresponding to the formula $[\text{HgPy}_2]\text{Cr}_2\text{O}_7$. The ppt. is insol. in water contg. dichromate and pyridine, in alc. and in ether. To 100 cc. of Hg^{++} salt soln. add 2 g. of powd. $(\text{NH}_4)_2\text{Cr}_2\text{O}_7$ and 1 cc. of pyridine as soon as the dichromate has dissolved. These quantities of reagents are sufficient for 0.30 g. of Hg. Stir for 5-10 mins., filter through a Gooch crucible and wash 4-5 times with water contg. 0.5 g. of $(\text{NH}_4)_2\text{Cr}_2\text{O}_7$ and 0.5 cc. of pyridine per l. Then wash with 80% alc. contg. 1 drop of pyridine for each 10 cc. of abs. used in prepg. the 80% soln. Finally wash with ether, dry in the air or in vacuum at room temp. and weigh. The ppt. contains 34.90% of Hg. The results are accurate. W. T. H.

Potentiometric determination of titanium in the presence of other metals, particularly iron. H. BRINTZINGER AND W. SCHIEFERDECKER. Univ. of Jena. *Z. anal. Chem.* 76, 277-80(1929).—By titration with CrCl_2 it is possible to det. the end point corresponding to the reduction of Ti^{++++} to Ti^{+++} accurately, although the break in the titration curve is small. In the presence of Cu, potentiometric titration shows that the Ti reduction is intermediate between the reduction of Cu^{++} to Cu^+ and Cu^+ to Cu^0 . When Fe is present with Ti the first break in the curve corresponds to the reduction of Fe^{+++} to Fe^{++} and the second to the reduction of the Ti. Good results are reported for the potentiometric detn. of Cu and Ti in the presence of one another and for the detn. of Fe and Ti. W. T. H.

Determination of tin in wires insulated with rubber. A. LEJEUNE. Inst. Meurice-Chimie, Brussels. *Bull. soc. chim. Belg.* 38, 25-30(1929).—To det. Sn in rubber-insulated wires, it is imperative to use a 5-m. sample at least, since the Sn coating is usually uneven. Rubber is peeled off, and the last traces of it must be removed with C_6H_6 . The wire is then dissolved in HNO_3 (d. 1.36). SnO_2 is filtered and weighed. Cu has never been found in the ppt. ALBERT L. HENNE

Variations in silver assaying. F. C. JOHNS. *Chem. Eng. Mining Rev.* 21, 152-4(1929).—In N. S. W. in the Broken Hill field, it is stipulated that assays must agree within 0.5 oz. Ag per ton. With ores assaying 3-13 oz. Ag per ton, few umpire assays are necessary but when over 70 oz. of Ag per ton are present, the differences between the assays for the buyer and for the seller are so great that most of the assays have to be umpired. In this paper 3 methods of assay were studied to show the difficulty in getting concordant results. Two methods, that of scorification and pot assay using niter, give practically identical results; but pot assaying using an Fe rod for desulfurizing

causes greater losses in Ag. In spite of all that can be done, there are bound to be Ag losses due to volatilization and to absorption by the cupel. It is difficult to make proper allowance for these losses and considerable skill is necessary on the part of the operator.

W. T. H.

Zirconium. III. Influence of lithium, rubidium, cesium and magnesium upon the detection of potassium by zirconium sulfate. RUFUS D. REED AND JAMES R. WITHROW. Ohio State Univ. *J. Am. Chem. Soc.* 51, 1062 5(1929); cf. C. A. 23, 791.—With 2 cc. of reaction mixt., a soln. of $Zr(SO_4)_2$ contg. 8.7% of dissolved salt will show the presence of 1.0 mg. or more of K in the presence of Li, Rb, Cs, Mg, Na and NH_4 ions. Since this is not true of $Na_2Co(NO_2)_6$, H_2PtCl_6 and $HClO_4$, which are the best-known reagents for detecting K, the value of $Zr(SO_4)_2$ as a reagent is obvious.

W. T. H.

A new procedure for the detection of minute amounts of iodine. A. N. SUCHUKA REV AND SUISSOV. *J. Russ. Phys.-Chem. Soc.* 60, 609 71(1928). When a cell with Pt electrodes connected to a galvanometer is filled with 0.1 N KI soln. and placed between the poles of an electromagnet (field strength 2000 gauss), a deflection is produced which increases about 10 times on the addn. of a trace of I_2 to the soln. A similar effect is obtained when the cell is not placed directly in the magnetic field but in series with a loop of Al wire in the field. The phenomenon is explained as an increase in the induced current strength due to the depolarization of electrodes by I_2 . Similarly, when an e. m. f. of a few millivolts is applied to the cell electrodes the resulting current is 20 or more times larger in the presence of I_2 (or Cl_2 in 0.1 N KCl soln.). I_2 in concns. which produce no color with starch can be detected by this method. B. SEYENKOFF.

The origin of the alkali and alkaline earth metals as impurities in reagents. A. FROST. *Trans. Inst. Pure Chem. Reagents* (Moscow) 1927, No. 6, 38-40. By analyzing NH_4 alum and $CdSO_4$ it is shown that the traces of alkali and alkaline earth metals found are not introduced during the analysis but are present in the original reagents.

G. B. KISTIAKOWSKY.

Quantitative estimation of chloride ion in reagents. A. FROST. *Trans. Inst. Pure Chem. Reagents* (Moscow) 1927, No. 6, 35-7. The effects of acids and salts on the nephelometric detn. of Cl^- by $AgNO_3$ have been investigated. With 20 cc. of soln. it was found that 1 cc. of 0.1 N $AgNO_3$ produces the max. turbidity and that further additions of this salt have no effect. Nitric acid first increases and then decreases the turbidity. The max. was obtained with about 1.5% acid. H_2SO_4 acts similarly. NH_4NO_3 , KNO_3 , K_2SO_4 , Na_2SO_4 , $KClO_4$, $CdSO_4$ and $Zn(CH_3COO)_2$ present in quantities of 1 g. in 20 cc. of soln. increase all the turbidity by about 40% when chloride ion concn. is 0.55 to 0.020 mg. in 20 cc. and by about +20% when the concn. is 0.44 to 0.01 mg. in 20 cc.

G. B. K.

Determination of the fluosilicate anion and of the fluoride ion in general. H. BAYLE AND L. AMY. *Compt. rend.* 188, 702 4(1929). By heating a fluoride with SiO_2 and concd. H_2SO_4 in a 60-100 cc. flask it is possible to transform the fluoride into SiF_4 gas. This gas when passed into water gives H_2SiF_6 and H_2SiO_3 . The H_2SiF_6 can then be converted into K_2SiF_6 , insol. in alc. and this salt can be titrated with KOH soln., phenolphthalein being used as indicator. Place the substance together with some SiO_2 in the distg. flask and add 10-20 cc. of concd. H_2SO_4 . Pass a current of dry air through the flask for 30 mins. to expel all moisture. Then raise the temp. to 100° and keep at this temp. for several hrs. Pass the gas through a tube dipping under Hg , so that it does not become clogged, and then into water. At the end of the expt. wash out this tube. From the H_2SiF_6 soln. thus obtained in the receiver, ppt. K_2SiF_6 by the addn. of an excess of KCl and enough 95% alc. to double the vol. of the soln. It is well to add also some ether. Neutralize carefully with KOH, using phenolphthalein as indicator. With pure H_2SiF_6 this neutralization would correspond to 2 KOH for each mol. of H_2SiF_6 . The ppt. of K_2SiF_6 , however, can be made to react with 4 more mols. of KOH as follows: Add a few cc. of 0.1% $CaCl_2$ and evap. off the ether and alc. on the water bath. Take up in hot water and titrate with KOH, using phenolphthalein as indicator.

W. T. H.

Applications of ceric sulfate in volumetric analysis. V. Potentiometric study of the reaction between ferrocyanide and ceric ions. N. HOWELL FURMAN AND OLIVER M. BYAM. Princeton Univ. *J. Am. Chem. Soc.* 51, 1128-33(1929).—The potentiometric titration of $Fe(CN)_6^{4-}$ with $Ce(SO_4)_2$ is accurate in solns. which are 1-5 N in H_2SO_4 or 0.5-2 N in HCl . The reverse titration is only accurate when the greater part of the $Fe(CN)_6^{4-}$ is added very rapidly. In the former case, the presence of a little Fe^{+++} in the Ce^{++++} soln. causes a greenish coloration (due to Prussian blue, which

disappears sharply at the end point so that the titration can be carried out with a visual end point which is practically identical with the potentiometric.

water, add 5 cc. of the sample and 5 cc. of 10% KI. Let stand overnight in a closed vessel shielded from direct sunlight and titrate the free I_2 with 0.1 N $Na_2S_2O_3$. The results are high because of the liberation of some I_2 in the absence of active O. When this amt. of I_2 is subtracted, the corrected results agree closely with those obtained by gas analysis.

Determination of sulfuric acid in the presence of chromic acid. B. SOYENKOFF. *Trans. Inst. Pure Chem. Reagents* (Moscow) 1927, No. 6, 31-4. Pptn. methods being unsatisfactory for the detn. of H_2SO_4 in the presence of CrO_3 , it is best to det. the total free acid by adding an excess of NaOH soln. and titrating back with H_2SO_4 using Congo red as indicator. The end point corresponds to the formation of $Na_2Cr_2O_7$ and Na_2SO_4 . To det. CrO_3 , make the soln. strongly acid and titrate iodometrically. G. B. K.

Determination of selenium dioxide in sulfuric acid. Tz. RAIKHINSTEIN. *Trans. Inst. Pure Chem. Reagents* (Moscow) 1927, No. 6, 27-30. A colorimetric detn. of SeO_2 in concd. H_2SO_4 has been worked out by using codeine phosphate in a modified Dragendorff method. By adding 0.1 cc. of a 4% aq. soln. of codeine phosphate to 10 cc. of SeO_2 soln. in concd. H_2SO_4 one obtains convenient depth of color between concns. 0.01% to 0.00005% SeO_2 . Arsenic acid in H_2SO_4 gives no perceptible coloration when present in concn. less than 1%. Ferric salts give a blue coloration of a different hue than SeO_2 . First indications of color appear when the Fe content exceeds 0.0015%. In the presence of phosphoric acid color appears only when the concn. of Fe is greater than 0.0074%. G. B. KISTIAKOWSKY

Determination of chloride in bromides. R. K. McALPINE. Univ. Michigan. *J. Am. Chem. Soc.* 51, 1065-73 (1929). With 1 g. samples it is possible by the proposed method to remove the Br and weigh the chloride as AgCl within about 0.1% of the original wt. of sample. With 10 g. samples, directions are given which will det. as little as 0.2% chloride with satisfactory accuracy. The method depends upon the preferential oxidation of the bromide by treating with $KMnO_4$ in solns. of definite acidity and in the presence of acetone which unites with the Br as fast as it is oxidized. The excess of $KMnO_4$ is removed by treatment with H_2O_2 and the chloride pptd. by treatment with $AgNO_3$ in the presence of dil. HNO_3 . W. T. H.

Modified iodine pentoxide method for determination of carbon monoxide in air and blood. MATHEW J. MARTINEK AND WM. C. MARTI. Health Dept., Chicago. *Am. J. Public Health* 19, 293-9 (1929). The method depends upon the liberation of I_2 by the interaction of I_2O_5 and CO and titration with 0.02 N $Na_2S_2O_3$ in a microburet. The app. can be used for the detn. of as little as 0.001 cc. of CO in 3 cc. of blood and the av. error in detg. CO in gasoline exhaust was 6% of the actual CO content. The gases under examn. are sucked successively through cold, concd. H_2SO_4 , H_2SO_4 heated to 150°, cold, concd. H_2SO_4 , activated charcoal, soda lime, solid KOH and "dehydrite." Then they are passed through a tube contg. "seasoned" I_2O_5 heated to 150° and the liberated I_2 is absorbed in a specially constructed absorption bulb contg. 10% KI soln. The gases do not come in contact with rubber connections at any place. W. T. H.

Determination of water in micas. K. I. VISKONT AND I. P. ALIMARIN. *Trans. Inst. Econ. Mineral Met.* (Moscow) 1928, No. 40, 18 pp. Considerable difficulty has been encountered in the detn. of H in silicates, like the micas, which retain the combined H very persistently even at high temp. and because some of the H is likely to be evolved as such by the oxidation of FeO to Fe_2O_3 by H_2O at the high temp. These difficulties can be overcome, however, and the method of Penfield used to advantage, if the substance is placed in a Pt boat together with some Pt black some PbO and some dry Na_2WO_4 powder. W. T. H.

The value of the combustion method in the determination of the cotton content of asbestos products. H. SOMMER. Staatl. Materialprüfungsamt, Berlin-Dahlem. *Gummi-Ztg.* 43, 1107-8 (1929).—The proportion of combined water in asbestos depends upon the quality of the asbestos and varies considerably among various grades. Therefore, the loss on combustion of an asbestos product is an uncertain and misleading indication of the presence of cotton, and a loss on combustion may be made up of both cotton and combined water, or either alone. Because of uncertain results recorded in the literature, the hygroscopic water, the loss after several hrs. at 600°, and after 1 hr. at 900° were detd. in 18 types of asbestos from various countries. The hygroscopic water varied from 0.34 to 2.37%, the loss at 600° from 0.28 to 13.18% and the

loss at 900° from 0.45 to 15.80%. A survey of various methods leads to the conclusion that the only satisfactory method for detg. cotton is the cuprammonium method of Heermann and S. (cf. C. A. 16, 4068). Continued use of this method has shown its great reliability, and if the treatment is prolonged, silk can also be removed from the asbestos.

C. C. DAVIS

The chemical analysis of silicates. JOSEF ROBRITSCHER. *Sprechsaal* 61, 233-5, 257-60(1928); cf. C. A. 22, 3109.—The recent methods for pptg. various cations by *o*-hydroxyquinoline are applied to the analysis of silicates.

R. A. HEINDL

The determination of total carbon in metallurgical products. JOSÉ GONZÁLEZ-RODRÍGUEZ Y GRÍ. *Quim. ind.* No. 61, 24-39(1929).—After a critical discussion of (a) Fleming's method, (b) Strohm's method and (c) the Cain-Maxwell method, comparative results in the analysis of various samples of Fe, steel and Fe alloys, it is shown that F.'s method gives consistently good results, S.'s method gives low values and is inapplicable to Fe-Mn and resistant iron. C.'s method gives higher results and, on the whole, is not satisfactory.

S. L. B. ETHERTON

Analysis of chrome ores. THOMAS R. CUNNINGHAM AND THOMAS R. MCNEILL. Union Carbide Res. Lab. *Ind. Eng. Chem., Anal. Ed.* 1, 70-2(1929).—Methods are given for the detn. of Cr, Fe, Al, SiO₂, CaO and MgO. Cr is detd. in a sep. sample which is fused with Na₂O₂. After the melt is leached with water and the Fe crucible removed, the soln. is treated with dil. H₂SO₄ and then HNO₃ is added. Then, after treatment with KMnO₄, AgNO₃ and (NH₄)₂S₂O₈, the procedure follows the usual method for detg. Cr in steel by the persulfate method. For the detn. of the other constituent it is recommended to digest a sample of the ore with H₂SO₄ and HClO₄; or, if the quartz content is high, to fuse with soda and borax. In the latter case, the B is removed by treatment with HCl and MeOH. After complete reduction of the Cr₂O₇²⁻ to Cr³⁺, the Fe²⁺ is oxidized with HNO₃ and the Ti and Fe are pptd. with cupferron. The Fe and Ti are then detd. in the usual way. In the filtrate from the cupferron ppt. the excess reagent is oxidized and the Cr³⁺ converted to Cr₂O₇²⁻ again by evapn. and heating with KClO₃ and HNO₃. After this the Al is pptd. by NH₄OH. The wt. of Al₂O₃ should be corrected for P₂O₅ and Cr₂O₃ which it will contain in small quantities. It is next recommended to add (NH₄)₂HPO₄ and ppt. both Ca and Mg as phosphate. The ppt. is ignited and weighed. It is dissolved in HCl and from the soln. CaSO₄ is pptd. by evapn. and treatment with H₂SO₄ and alc. The CaSO₄ ppt. is dissolved in dil. HCl and the Ca finally pptd. as oxalate. In the filtrate from the CaSO₄ ppt. Mg is detd. by the bismuthate method. Mg is computed from the wt. of the previous phosphate ppt. after allowing for the Ca₃(PO₄)₂ and Mn₃P₂O₇ which it contains. No values are given to show the accuracy of this procedure.

W. T. H.

Determination of sulfur in organic compounds. E. A. SMITH AND J. W. LEIN. *Can. Chem. Met.* 12, 287-8(1928).—The S content of samples of Ba lignosulfonate was detd. by the following 5 methods: Eschka's method, fusion with Na peroxide followed by gravimetric detn. of sulfate, Klason's method in which the oxidation is carried out by the fumes from asbestos soaked in HNO₃ in a combustion tube, Apitzsch's method using Pt gauze and O₂, and Carius' method. The most consistent and highest results were obtained by Carius' method, which was closely approached by Apitzsch's method. Losses evidently occurred in the other methods, which gave very variable results.

R. C. A.

A colorimetric method for the determination of butyric acid. R. J. ALLEN, W. H. PETERSON AND E. B. FARR. Univ. of Wis. *J. Bact.* 17, 79-87(1929).—The soln. to be tested was made to a definite strength, treated with a CuCl₂-HCl reagent (8.26 g. of CuCl₂·2H₂O in 1000 cc. of N HCl) and the mixt. shaken with CHCl₃. Known mints. of butyric and acetic acids treated in the same manner were used as standards. By careful standardization, the results with 17 butyric-acid-producing cultures of bacteria checked well with the Duclaux method. Good results were obtained in the presence of either acetic or formic acids.

A. W. D.

Method for determining formaldehyde. FARRIS LUTHER. Univ. Prague *Z. chem.* 76, 241-54(1929).—The method consists in making the HClO combine

with KCN and detg. the excess of the latter. Add 10 cc. of approx. 1.7 N HCHO soln. to about 75 cc. of KCN soln. carefully measured into a distg. flask. Mix well and allow to stand about 5 mins. Then add 40 g. of tartaric acid dissolved in water. Dil. to 200 cc. and distil slowly, eventually using a stream of air to help drive over the HCN. Collect the distillate in 2 absorption flasks, each contg. 50 cc. of clear 10% KOH soln. Finally titrate the KCN formed with AgNO_3 by the Liebig method, adding KI soln. to sharpen the end point.

W. T. H.

Applications of the nitrile method. I. Binding of hydrocyanic acid by albumin. II. Determination of formaldehyde in albuminous media. III. Quantitative relations between formaldehyde and albumin. FRITZ LIPPICH. Univ. Prague. *Z. anal. Chem.* 76, 255-60(1929).—In the preceding abstr., it was shown that HCHO can be detd. satisfactorily by making it form acetonitrile by interaction with KCN. The nitrile holds the CN radical sufficiently strongly so that the excess KCN can be detd. by adding tartaric acid and distg. off HCN from the alkali cyanide alone. It is proposed to call this procedure "the nitrile method." Before applying the method to various media, it is necessary to det. by expt. the extent to which these media react with KCN. Expts. with egg albumin, peptone, gelatin and several casein products show that these do not combine with HCN to any appreciable extent, or at least to a degree such that the HCN is not liberated by treatment with tartaric acid. The mols. of genuine albumins, globulins, gelatins, caseins, etc., do not contain free aldehydic, ketonic or phenolic groups. For very exact measurements of small quantities of KCN, however, it is necessary to allow for a slight absorption of HCN by these substances. The nitrile method, therefore, seems suitable for studying the combination of HCHO with proteins. It is shown by expt. that the presence of these substances does not make the nitrile more readily decomposable by tartaric acid. The amt. of HCHO absorbed by gelatin soln. was studied by allowing the HCN soln. to react with gelatin soln. for periods ranging from 1 min. to 87 hrs. The amt. of HCHO absorbed by 1 g. of gelatin increased slowly with the time from 8.2 to 24.6 mg. With 4 samples of casein, 4 g. of the protein united with 3.3-9.8 mg. of HCHO.

EDGAR T. WHERRY AND J. F. SCHAIER

Determination of the melting points of sulfide- and arsenide minerals. L. H. BORGSTRÖM. III. *Nord Kemistmodel* (Finland) 1928, 169-71.—The method discussed is very similar to the common method of detg. the m. p. of org. compds. For temp. baths the following were used: over 810° , NaCl , $630-850^\circ$, 7 pts. Na_2SO_4 and 3 pts. NaCl ; $380-650^\circ$, 3 pts. KCl and 1 pt. LiCl and $220-450^\circ$, 55 pts. NaNO_3 and 45 pts. KNO_3 . For temp. measurement a LeChatelier thermoelement, and for capillaries hard glass or quartz, were used. M. p. of AsS = 310° , As_2S_3 = 325° , Sb_2S_3 = 546° , Bi_2S_3 = 718° , $\text{Pb}_3\text{As}_2\text{S}_5$ = 450° , $\text{Ag}_3\text{Sb}_2\text{S}_5$ = 470° and Ag_3SbS_5 = 480° . Metal sulfides and arsenides gave m. ps. between 800° and 1200° , while many decomposed. Most of the m. ps. of metallo-sulfarsenides, sulfantimonates and related compds. fell between 400° and 600° , and some Bi sulfosalts above 800° .

O. A. NELSON

The presence of atacamite among the incrustations of Vesuvian lava in 1631. G. CARONNI. *Rend. accad. sci.* (Napoli) [3], 34, 78 83(1928).—Crystallographic measurement as well as chem. analysis has proved that crystals of atacamite, $\text{CuCl} \cdot 3\text{Cu}(\text{OH})_2$, are present in the lava incrustations from the eruption of 1631.

A. W. CONTIERI

X-ray investigation of the microcrystalline iron-hydroxide minerals. J. BÖHM. Univ. Freiburg. *Z. Krist.* 68, 567-85(1928).—The supposed existence of a series of hydrates of Fe_2O_3 , such as $\frac{1}{2}\text{H}_2\text{O}$ (hydrohematite or turgite), $\frac{1}{3}\text{H}_2\text{O}$ (hydrogoethite), $\frac{1}{4}\text{H}_2\text{O}$ (goethite), $\frac{1}{5}\text{H}_2\text{O}$ (limonite), $2\text{H}_2\text{O}$ (xanthosiderite) and $3\text{H}_2\text{O}$ (limnrite) is disproved. The only crystal. compd. is $\text{Fe}_2\text{O}_3 \cdot \text{H}_2\text{O}$, which is dimorphous, occurring as goethite (α -form) and lepidocrocite or "rubinglimmer" (γ -form). The α -form is orthorhombic, with $a = 4.60$, $b = 10.01$ and $c = 3.04$ A. U.; axial ratio for this 0.459:1:0.303. The calcd. d. is 4.195. The γ -form is also orthorhombic, with $a = 3.85$, $b = 12.5$, $c = 3.07$ A. U.; the axial ratio is 0.308:1:0.246 and the calcd. d. is 3.97. Powder photographs from 33 specimens, including xanthosiderite, limonite, ocher, "Bohners," "Schwarzhäuten," brown "Glaskopf," "Brauneisen-stalagmit," gave

patterns identical to those obtained from goethite or synthetic $\text{Fe}_2\text{O}_3 \cdot \text{H}_2\text{O}$. The only addnl. lines were due to impurities, such as quartz. There was evidence of amorphous material in a few of the samples. Addnl. water in excess of that called for by the formula is attributed to adsorbed H_2O or to impurities. Hydrohematite and red "Glaskopf" give the $\alpha\text{-Fe}_2\text{O}_3$ pattern. Some specimens of "Sumpferz" and "Pecherz" gave no lines at all, indicating an amorphous condition. No lines of $\gamma\text{-Fe}_2\text{O}_3 \cdot \text{H}_2\text{O}$ were obtained from any of the specimens. The structures of fibrous hematite and limonite are discussed. When a fiber of α -limonite is dehydrated, its b -axis becomes the c -axis of the new hematite structure, and, conversely, its c -axis becomes the new b -axis.

L. S. RAMSDELL

Pelargosite from Tremonti, Adriatic Sea. F. ONORATO. *Bull. soc. geol. ital.* **44**, 17(1926).—Pelargosite, $d. 2.834$, $H 4$, $n_D 1.529$, contained: CaCO_3 79.47, MgCO_3 3.13, SrCO_3 2.27, CaSO_4 3.94, Fe_2O_3 0.23, Al_2O_3 0.57, NaCl 3.66, KCl 1.63, SiO_2 0.47, H_2O 2.44, org. material 2.10%.

B. C. A

Stoichiometry of silicates. B. GOSSNER. Univ. Munich. *Z. angew. Chem.* **42**, 175-9(1929).—The compn. of natural silicates shows a slight deviation from a simple numerical relationship between SiO_2 and MO , a small excess of SiO_2 generally being found. This is investigated for a no. of *olivines*, *almandines* and *sandines*. With olivine, the relation $\text{SiO}_2:\text{M}'\text{O}$ is about 1:1.96, and the relation $\text{SiO}_2:\text{M}''\text{O}$ is about 1:2.03 ($\text{M}' = \text{Mg} + \text{Fe} + \text{Ca}$; $\text{M}'' = \text{Mg} + \text{Fe} + \text{Ca} + \text{H}_2$), a slight excess of SiO_2 in the first case and a slight deficiency in the second case. With almandine, the deviation from a simple numerical relationship is apparently very great, the ratio $\text{SiO}_2:\text{M}''\text{O}$ being about 2.75:1, but correcting for isomorphous replacements of the type $\text{SiFe} = \text{Al}_3$, there is then an excess of SiO_2 . With *nepheline* and the *zeolites*, a similar excess of SiO_2 is found, but with *sanidine* there is a slight deficiency. The occurrence of gaps in the structure is a possible explanation of this phenomenon. H. STOERTZ

Geologic remarks on phosphates from Niezwiska, Poland. JAN NOWAK. *Przemysl Chem.* **11**, 709-21(1927).

A. C. ZACHLIN

Polish phosphates. JULIAN TOKARSKI. LWOW Polytech. *Przemysl Chem.* **11**, 58-72(1927).—After a review of earlier work on the subject T. describes the phosphate deposits near Grodno and Rachow and those at Niezwiska.

A. C. ZACHLIN

Chemical composition of rock-making nephelite. JOZEF MOROZEWICZ. *Bull. intern. acad. Polonaise* No. 3A, 111-25(1928).—On the basis of 5 new chem. analyses and a complete survey of the literature, M. concludes that the correct formula for nephelite is $\text{K}_2\text{Al}_2\text{Si}_3\text{O}_{10} \cdot n\text{Na}_2\text{Al}_2\text{Si}_2\text{O}_8$ (where n is usually 4). Attention is called to the fact that nephelite is slowly attacked by moist air, which tends to alter its compn.

J. F. SCHAIER

The crystal structure of garnet. G. MENZER. Univ. Berlin. *Z. Krist.* **69**, 300-96(1928).—A detailed study of the garnet group, including the Ca-Al , Ca-Fe , Ca-Cr , Fe-Al , Mn-Al and Mg-Al varieties. Several new analyses are given. Garnet has a body-centered cubic lattice; the space group is O_h^{10} . The values for d_{100} are 11.840, 12.026, 11.950, 11.497, 11.603 and 11.510 ± 0.003 A. U., resp., for the above-mentioned varieties. The unit cell contains 8 mols. of $\text{M}_3'\text{M}_2'''\text{Si}_2\text{O}_{12}$. Other formulas proposed for garnet are incompatible with this unit cell. The positions of the bivalent, trivalent and the Si atoms are fixed by symmetry. The parameters for the O atoms are detd. for each variety. The arrangement is not the same as that of Nishikawa (C. A. **11**, 3170). Each Si atom is surrounded by O atoms at the corners of a tetragonal bipyramid, and each trivalent atom by O atoms at the corners of a distorted octahedron. Interatomic distances are calcd. and compared with values from other sources.

L. S. RAMSDELL

Garnet sand at Hel, on the Baltic Sea. W. WAROCKI. Krakow Univ. *Bull. intern. acad. Polonaise* 1928, 439-44.—A description of sand found at Hel together with the mechanical analysis, a sepn. of the lighter constituents with CHBr_3 , physical consts. and optical researches.

ALBERT L. HENNE

The chemical constitution of the micas. IV. Phlogopite. Part 1. JOHANN JAKOB. *Z. Krist.* **69**, 217-25(1928); cf. C. A. **21**, 3861.—Analyses are given for 8 phlogopites and 1 manganophyllite. Optical data are included for 5 of the specimens. The variations in compn. are explained by combinations in different proportions of simple mols. common to all.

L. S. RAMSDELL

The approximate content of gallium in the green kaolin from Tanokami. The existence of gallium in the solar chromosphere. S. IIMORI. *Sci. Papers Inst. Phys. Chem. Research, Tokyo*, Supplement 10, No. 8, 1-4(1928).—Ga has been estd. in the green kaolins from Tanokami (cf. C. A. **22**, 1119, 1121) by the optical method of Fapish

and Holt (*J. Phys. Chem.* 32, 142(1923)); the Ga content of the mineral is about 0.004 to 0.0004%. It is believed that Ga exists in the solar chromosphere, but the evidence is meager. The solar spectrum should be investigated in the near ultra-violet range with a view of finding the lines 2943.77 and 2944.29, which would be the best evidence of the presence of Ga.

ALBERT L. HENNE

The composition of tectites, particularly those from Cambodia. A. LACROIX. *Compt. rend.* 188, 284-8(1929).—The billitonite from Billiton, and the mineral called by Damour "explosive obsidianite from India" belong to the same deposit, represented by the large tectite in the Singapore museum. D. had noted that when attempting to break this obsidian, it shattered into fragments with violence. L. opened a spherical specimen 8 cm. in diam. with precautions described and found an eccentric spherical cavity of 6 cm. diam. The rupture is due to the presence of gas within. There are 3 types of tectites (a) Darwin glass, Tasmania, (b) moldavites of Moldavia and Bohemia, (c) australites and billitonites of Malaya and the tectites of Cambodia. Tectites have the common character of high free SiO_2 , high free Al_2O_3 , no phosphoric acid and a K content greater than the Na. L. gives a genetic hypothesis, and analyses of Darwin glass, moldavites, australites and billitonites, making 16 samples in all. The morphological, phys. and chem. properties of Cambodia glass resemble billitonite from Malaya and will be described later.

S. L. B. ETHERTON

• **Operative causes in ore deposition.** H. C. BOYDELL. *Bull. Inst. Mining Met.* No. 277, 85 pp.(1927); No. 280, 23-9; No. 284, 41-2; No. 285, 1-5; No. 287, 2 pp.(1928).—B. gives a general summary of the phys.-chem. principles underlying the deposition of ores from aq. solns., including in his paper such titles as H-ion concn. of ore solns., effect of temp. and pressure on concn., deposition due to evapn., change in temp., mixing of solns., length of time necessary for deposition, ore deposition from colloidal solns. and modes of deposition from colloidal ore-forming solns. The influence of pressure on limestone contact-metamorphic deposits is discussed at length and the reversibility of the chem. reactions stressed. In the discussion, V. M. Goldschmidt calls attention to a fundamental error in Boyde's statements concerning the reaction $\text{CaCO}_3 + \text{SiO}_2 \rightleftharpoons \text{CaSiO}_3 + \text{CO}_2$.

J. F. SCHAIRER

Ore genesis. JOHN A. GRIMES. *Mining and Met.* 9, 532-6(1928).—G. summarizes the modern theories concerning the genesis of ores genetically connected with igneous rocks. The result of progressive changes in the character of the solns. especially as regards their acidity is emphasized. Geological evidence points to the conclusion that the emanations from a cooling magma change radically from time to time and probably this change is continuous. The progressive change from the acid-gaseous to the alkaline-liquid type may be explained by the difference in pressures and temps. which would permit the escape of steam and acids as gases with attendant concn. of the ore-forming minerals in alk. soln.

J. F. SCHAIRER

The ferruginous sands of Necocha. Chemical composition and metallurgical application. PEDRO T. VIGNAU. *Rev. facultad cienc. quim. Univ. La Plata* 4, No. 2, 1-32(1927).—Microscopic examn. of the magnetic components showed magnetite, ilmenite, hornblende and picrotitanite. The coarser fraction of the nonmagnetic minerals contained quartz, plagioclase and hornblende. The fine fraction contained ilmenite, magnetite and some hornblende. Of a 10 kg. sample, there was 29.27% magnetite, 24.76% ilmenite, 27.89% medium sand and 80.3% common sand. These analyzed as follows:

Factor	Magnetite	Ilmenite	Medium Sand	Coarse Sand
Density	4.6908	4.2785	3.6093	2.8877
Moisture at 105°	0.079%
Fe_2O_3	76.599%	62.86%	41.114%	22.62%
TiO_2	15.940%	22.55%	8.5%	2.05%
SiO_2	1.80%	7.92%	45.3%	57.18%
MnO_2	3.71%	4.80%	1.71%	1.28%
Al_2O_3	1.19%	1.11%	2.22%	12.65%
MgO	0.50%	0.45%	0.31%	0.28%
CaO	0.08%	0.2%	0.71%	3.63%
Not detd.	0.1%	0.1%	0.11%	0.12%
Total Fe	55.44%	49.5%	29.76%	16.37%

The methods of analysis are discussed at length. Titaniferous sands are found on both sides of the Andes, along both sides of the South American littoral and in the interior, particular places being named. The Necocha sands extend about 15 km. at 30-80 m.

width and most deposits are similar so that there is no shortage of material. Similarity is brought out by the analyses given. Metallurgical products are discussed with analyses. V. adduces reasons for considering that economic working is practicable. The bibliography contains 72 references.

S. L. B. ETHERTON

Origin of iron ores of Iron Mountain and Pilot Knob. JOSEPH T. SINGEWALD, JR., AND CHARLES MILTON. *Am. Inst. Mining Met. Eng., Tech. Publication No. 197, Class 1, Mining Geology, No. 22*, 12 pp. (1929).—Evidence is deduced supporting Crane's theory of the origin of the specular hematite deposits of Mo. The ore bodies of Iron Mountain are of replacement character. In the mine are seen olive-green garnet rock contg. hematite, quartz, calcite and an amphibole. The porphyry contained orthoclase, plagioclase, quartz, hematite, sphene, chlorite, epidote and garnet, thus indicating high-temp. mineralization. The Shephard Mountain deposits are more decidedly fissure fillings and the mineral assemblage suggests hypothermal mineralization. The principal minerals of the rock at Cedar Hill are quartz, orthoclase and muscovite. The replacement and other phenomena indicate high-temp. mineralization under pegmatitic conditions. The relation of ore to gang and the constituent minerals at Pilot Knob indicate epigenetic high-temp. mineralization. All stages of replacement are seen.

H. C. PARKIN

Economic minerals of the pegmatites. JOSEPH P. CONNOLLY. *Black Hills Engineer* 17, 21-38 (1929).—The formation of spodumene $\text{LiAl}(\text{SiO}_3)_2$ is still not quite settled; it is mined for Li, and crystals 47 ft. long occur. The common material is variable; theoretically 9.4% Li_2O should be present, whereas it varies from 0.2 to 6%. LiOH is used in alk. electrolytic type storage batteries, LiBr , LiI in photography, LiCl for red light in signals, Li citrate and carbonate and phosphate in medicine. Amblygonite, Li-Al phosphate, should contain 10% LiO but runs less; it is more easily worked for Li and occurs in pegmatites. Lepidolite, a complex silicate of the mica class, is used now in special glasses. Black Hills lepidolite contains Cs and Rb. Triphylite, lithiophilite are Fe-Mn phosphates. Feldspar is abundant in this region. It is used for fine china and potteries, enamels, finer grades for artificial teeth, and as an abrasive in soaps. Mica, one of the principal minerals of the granite group, is used as separator in dynamo commutator segments, in condensers and the like, in lanterns, goggles, windows of conning towers on battleships, as diaphragms in phonographs, head phones, etc. Splittings are used to build up sheets with shellac. Mica occurs along with tin and may be profitably worked. Beryl, Be Al silicate, is found in the region. From it is made $\text{Be}_3(\text{NO}_3)_4$, which is used to harden gas mantles. The mineral greatly improves porcelain. Columbite tantalite is found, the first running 18-40% Ta oxide and the second up to 80%. It is used for steels and acid-resisting parts. Andalusite-sillimanite, AlSiO_3 , is used in spark plugs and has a future in the refractory industry. Quartz chiefly of the pink variety is found and a Cs silicate, pollucite, is also found. Small deposits of cassiterite, SnO_2 , are worked.

S. L. B. ETHERTON

Exposition at Karabugaz in 1927. B. L. RONKIN AND I. M. KUCHUK. *Inst. anal. phys. chim. (Leningrad)* 4, 225-46 (1928).—Natural deposits of NaCl and Na_2SO_4 are being worked in the Karabugaz district of the Caspian Sea. The Na_2SO_4 compd. is dehydrated by means of the natural solar heat. The actual yield of the anhydrous product is 25 to 27%.

REA MA

Relation of diatoms to petroleum formation. A. P. V. STAHL. *Petroleum* 24, 1278-9 (1928).—The presence of oil droplets in the cellular spaces of diatoms gives weight to the hypothesis that these organisms have played an important part in oil formation.

Contact relations of the Donagel granite. GERALD ANDREW. *Mem. Proc. Chester Lit. Phil. Soc.* 72, 211-20 (1927-8).—A. concludes that when rocks of similar mineralogical compn. are incorporated with a molten granitic magma, the incorporation is largely mechanical with only minor chem. readjustments aided by the volatile constituents of the magma. Analyses of an oligoclase = porphyroblast schist and banded gneiss are included.

J. F. SCHAGER

Composition of basaltic lava of Indo-China. A. LACROIX. *Compt. rend.* 186, 985-91 (1928).—The decompn. of these rocks gives rise to the red soil upon which are the chief riches of Indo-China—rubber and coffee plantations—hence the desirability of an accurate analysis of the rocks. The analytic limits are: SiO_2 41-54, Al_2O_3 11-17, Fe_2O_3 2-8, FeO 5-8, MgO 6-10, CaO 7-10, Na_2O 3-4, K_2O 0.5-2, TiO_2 2, P_2O_5 0.5, H_2O up to 2, MnO up to 0.2%. This basaltic series may have much free SiO_2 or, where there is a deficiency of SiO_2 , there may be much olivine. The first type includes

pyroxene and magnesian augite. Titanite and ilmenite may be found. The structure is doleritic and of variable grain.

Deep prospecting by boring at Ferrières-en-Bray (Lower Seine, France). PIERRE PRUVOST. Univ. Lille. *Ann. office nat. comb. liquides* 3, 429-57, 851(1928).—Borings by means of diamond drills to a depth of 1172.7 m. show that neither petroleum, coal, salt, workable H_2O or a large reserve of H_2O exists under the region of Bray. The

R. E. SCHAAD
Processes involved in the decomposition of wood with reference to the chemical composition of fossilized wood. SELMAN A. WAKSMAN AND KENNETH R. STEVENS. New Jersey Agr. Expt. Sta. *J. Am. Chem. Soc.* 51, 1187-96(1929).—Decompn. of wood under anaerobic conditions, as in peat bogs or in the process of fossilization, brings about the disappearance of the celluloses and hemicelluloses and a marked accumulation of the lignin complexes. The nature of the chem. processes involved in the decompn. of wood under aerobic conditions depends largely upon the micro-organisms concerned in the process. There is no justification in assuming that in the decompn. (rotting) of wood, oxycelluloses are formed as an intermediary step in the formation of "humus" from celluloses. These results, with those of other investigators, definitely establish the fact that the process of decompn. of wood is largely microbiological in nature and the nature of decompn. will depend upon the organisms active in the process, as influenced by the environmental conditions and the chem. compn. of the plant constituents. Tables are given showing the chem. compn. of decompd. wood, healthy wood, 2 samples of fossilized wood and the influence of alkali treatment of lignin from straw and peat.

C. J. WEST
The form of organically deposited calcium carbonate, and the influence of the medium. F. ULRICH. *Z. Krist.* 66, 513-5(1928).— CaCO_3 deposited by Cyanophyceae from nutrient solns. contg. Ca, at $15-22^\circ$, is rhombohedral. The habit of the crystals varies with the concn. of agar-agar.

H. G.
The frequency ratios zirconium-hafnium and columbium-tantalum. G. VON HEVESY AND K. WÖRSTLIN. *Z. Physik. Chem.* 139A, 605-14(1928).—Since, on account of the great similarity of Hf and Zr, it is improbable that one or the other should be preferentially removed from the silicate shell of the earth's surface, the assumption can be made that the relative frequencies of their occurrence in rocks and minerals represents their proportions in the solar system which can be identified with the relative nuclear stabilities. For Zr:Hf, the ratio, determined by x-ray analysis of a no. of minerals, is 50:1; for Cb:Ta it is not essentially greater than 1:1. For the latter pair, chemical similarity is not so great as to prevent the occurrence of a mineral whose predominant constituent is Ta; but no minerals are known in which the principal constituent is Hf, or in which the Hf content exceeds the Zr.

Foundry technology in 1928. HUBERT HERMANN. *Giesserei-Ztg.* 26, 61-77 (1929).—The mech. side of foundry technology is reviewed. J. W. W. S.
Remodeling of industrial works into foundries. A. F. HAGER. *Giesserei-Ztg.* 26, 3-14(1929).—The transformation of a steel mill into a gray-Fe foundry and of a Cu

mill into a gray- and white-Fe foundry are described and illustrated, together with a general flowsheet of foundry materials.

JOHN W. W. SULLIVAN

Efficiency in hydraulic current classification of finely crushed ores. T. GRAHAM MARTYN AND M. E. JOHN. *J. Chem. Met. Mining Soc. S. Africa* 29, 140-4(1928); cf. *C. A.* 22, 4089.—A discussion by J. R. Thurlow describes 6 tests applying the classification to Pt ores crushed to different degrees of fineness. Results indicate that the application of the classifier to Au ore and to Pt ores, using the flotation process, is limited. It should be useful in grading an ore preparatory to gravity concn. and may have a field in connection with the prepn. of sand for concrete and building purposes, and under certain conditions be useful in dressing Sn ores.

W. H. BOYNTON

Crushing and concentrating molybdenum ore at Climax, Colorado. WILLIAM J. COULTER. *Eng. Mining J.* 127, 476-80(1929).—The crushing plant, the transportation of the ore to the mill by aerial tram, and concn. to a high-grade product are outlined. The mill has a daily capacity of 1000 tons (909,000 kg.) with 90% recovery and an 87% concentrate with an av. concn. ratio of 105:1 at a total cost of 70¢ per ton. A flow sheet of the concentrator and several illustrations are included.

W. H. BOYNTON

A study of differential flotation. C. R. INCE. *Am. Inst. Mining Met. Eng., Tech. Pub. No. 195*, 24 pp (1929).—Six series of tests were run as follows: gang-slime coatings, bubble tests on slime-coated particles, bubble tests on slime-free particles, absorption tests, absorption tests with collecting agents and migration of slime particles. Results are tabulated and 8 conclusions drawn: (1) Slimes do or do not coat sulfide particles according to the elec. charges existing on the surfaces of the two types of particles; (2) the nature and magnitude of the elec. charge may be altered by dispersion agents; (3) the amount of slime coating may be controlled by means of dispersion agents; (4) a slime-coated sulfide does not float as readily as a slime-free one; (5) the floatability of a particle depends in part on the presence of a collecting agent at its surface; (6) cyanide and $ZnSO_4$ do not affect slime coatings; (7) cyanide and $ZnSO_4$ decrease the concn. of collecting agent at the surface of certain sulfides, rendering them less floatable; and (8) $CuSO_4$ is capable of restoring the floatability by permitting the concn. of collecting agent at the surface of the sulfide.

W. H. BOYNTON

Oxidized ore flotation at Chief Consolidated Mill. G. H. WIGTON. *Mining and Met.* 9, 541-2(1928).—Flotation of the oxidized minerals from siliceous ores is brought about without adding a reagent for producing a sulfide film. With sulfide filming, efficiency decreases rapidly with increase of hydrated iron oxides in the ore. Aero float (cresylic acid and P_2S_5) with ethyl xanthate is used as a frothing agent and collector of sulfides and oxidized minerals. Na silicate is used for conditioning. Amounts of reagents used per ton are 3 lb. Na silicate soln., 0.6 lb. Aero float and 0.5 lb. ethyl xanthate. Flotation of the slime present in the ball mill feed was unsuccessful. Differences between lab. control and mill operation were found to be due to differences in H-ion concn. After the development of the H-ion control in the grinding and flotation circuits steady com. operation of the mill was begun on oxidized ores from various parts of the district. Ball mill pH is held at 6.8 to 7.0, the primary flotation cells at 7.0 and the scavenger cells at 7.2.

J. W. SHIPLEY

Experiments with flotation reagents. A. F. TAGGART, T. C. TAYLOR AND C. R. INCE. *Am. Inst. Mining Met. Eng., Tech. Pub. No. 204*, 75 pp (1929). The experimental work on flotation reagents was classified as follows: (1) collecting agents; (2) frothing agents; and (3) inorg. reagents. (1) is subdivided into: (a) a method for quantifying collecting effect; (b) coating with undissolved collecting agents; (c) action of dissolved collecting agents. (2) is subdivided into: (a) a method for quantifying frothing effect; (b) relation between frothing effect and chem. compn. (3) is subdivided into: (a) methods of studying the effects of these reagents; (b) effect of slime dispersion; (c) effect on sulfides. A statistical study is made of the relation between structure and soly. of org. compds. and their functions in flotation.

W. H. BOYNTON

The recovery of apatite from waste ore slimes by flotation. WALTER LEYKEN AND HANST BIERBRAUER. *Mitt. Kaiser-Wilhelm-Inst. Eisenforsch. Dusseldorf* 10, 317-21(1928).—In the Swedish mine, Lekomberg, the Fe ores are sep'd by flotation. An intermediate product contg. 42% Fe and 1% P is obtained in this process. On screening it is found that most of the P is in the fine-grained material. By using Na palmitate with 200 g. of material and 600 cc. water, it was found possible to obtain a concentrate with 13% to 15% P and a recovery of 74-85%. The relatively large quantities of Na palmitate consumed (5 kg. per ton) may be avoided by recirculating the flotation liquor. Semi-works scale operation confirmed the lab. results.

HANS C. DRUS

The theory and classification of concentration tables. WALTER LUYKEN. *Mitt. Kaiser-Wilhelm-Inst. Eisenforsch. Düsseldorf* 11, 1-14(1929).—General discussion.

Zinc from sulfide ores. V. P. IL'INSKII AND A. P. SAGAIACHNUI. *J. Applied Chem. (Russia)* 1, 109-12(1928).—In the calcination of Zn sulfide ores contg. Fe at 650° to 750° the following reactions take place: $2\text{ZnS} + 2\text{O}_2 \longrightarrow 2\text{ZnO} + 2\text{SO}_2$; $2\text{SO}_2 + \text{O}_2 \longrightarrow 2\text{SO}_3$ (catalytic reaction of Fe_2O_3); $\text{ZnO} + \text{SO}_3 \longrightarrow \text{ZnSO}_4$, the Zn being entirely converted into ZnSO_4 in the atm. of SO_2 . Ninety-five % of Zn is dissolved after treatment with concd. acids (H_2SO_4 or HCl), whereby about 40% of elementary S is sepd. Eighty % of Zn is obtained from calcined ores after treatment with caustics, the soln. being free from Fe and Cu.

Zinc and lead deposits in Helgeland, Northern Norway. J. C. TORGENSEN. *Norg. Geol. Undersøkelse* No. 131, 69 pp. (with English summary of 10 pp) (1928).

Economic size of the open hearth. F. A. KING. *Mining and Met.* 9, 550-1 (1928).—Increasing economic efficiency and quality of product followed the use of larger furnaces. Deep furnaces require less limestone per ton of metal and the tendency to oxidation is reduced. Tilting furnaces are as efficient as the stationary type. Little bottom trouble has been experienced with either type at Weirton. The largest stationary open-hearth furnace yet constructed, 300 tons, made its first cast Feb. 4.

Blast-furnace and open-hearth practice. C. A. MEISSNER. U. S. Steel Corp. *Blast Furnace and Steel Plant* 17, 289-400(1929); cf. following abstract.—The practice of iron and steel production in the U. S. compares favorably with European practice. Some furnaces produce 850-950 tons and occasionally over 1000 tons of iron per day. European open hearth furnaces use blast furnace gas with coke-oven gas, a practice not followed in America. The newer units under construction in Europe differ little from the standard American furnace. The dimensions of 8 typical blast furnaces are given.

European blast-furnace practice. C. A. MEISSNER. U. S. Steel Corp. *Mining and Met.* 9, 537-8(1928); cf. preceding abstract.—The European tendency is to place high-pressure, superheated steam turbines in all new installations. Cleaning blast-furnace gas electrically is not practised in Central Europe. Screening of ores or crushing of coke is not generally practised in Germany. The paper includes details of furnace practice in France and Germany.

The blast-furnace process. IVAR BOHM. *Jernkontorets Ann.* 82, 145-208(1927).—From a full-charged charcoal furnace samples were taken at different levels. Ores of different character were used. The reduction begins with transition of specular iron ore to magnetite, and continues with contemporary formation of metallic Fe and FeO. The last of the FeO disappears only after the iron is fluid. The speed of reduction depends largely on the physical and petrographical character of the ore. Dense ores that by heating become porous are reduced faster than sinter, though this is porous to begin with. In a charge with ore rich in SiO_2 the formation of slag is complicated. In certain parts of the shaft the slag is considerably more acid than the final slag. In a charge without addn. of limestone, the slag is formed essentially through melting down of gang. Examn. of the movement of the charge in the blast furnace has given results differing from those of earlier investigators. The paper contains a series of diagrams, and photographs of ores, partly reduced ores, slags, iron and coal from different levels of the blast furnace.

Blast-furnace practice. R. P. BETHELL. *Proc. Staffordshire Iron and Steel Inst.* 42, 76-93(1926-27).—The mech. equipment and operation of a blast-furnace plant are briefly described. Ways and means of overcoming furnace irregularities are discussed in some detail.

A comparison of the coal-dust rotary (Brackelsberg) furnace and the cupola for producing superior temper castings. H. KALPKERS. *Gießerei-Ztg.* 26, 78-82(1929).—Older investigations of temper castings report 34-38 kg. per sq. mm. tensile strength and 2-3% elongation; a more recent investigation of 26 cupola cast irons reports an av. tensile strength of 38.9 kg. per sq. mm. tensile strength and elongation of 3.8% in 60 mm. Foundry "A" employing the coal-dust rotary (Brackelsberg) furnace for making temper castings reports an av. for 38 runs of 46.4 kg. per sq. mm. tensile strength and 5.4% elongation in 60 mm. Foundry "B," also using the Brackelsberg furnace, reports an av. for 60 runs of 42.5 kg. per sq. mm. tensile strength and 6.3% elongation. The range of values for foundry A is 39.1-52.2 kg. per sq. mm. tensile strength and 4.2-7.5% elongation; for foundry B 38.3-47.3 kg. per sq. mm. tensile strength and

3.3-11.3% elongation. The Brackelsberg furnace is illustrated by a photograph and 2 sketches. A cost comparison of the cupola and Brackelsberg furnace, based on 2 assumptions regarding fuel consumption, indicates that the cost of running 1 ton of Fe in the cupola is 15.72 M. and in the Brackelsberg furnace 9.39 M.

JOHN W. W. SULLIVAN

The influence of oblique charging of the cupola on the smelting process. E. KNOPFICK. *Giesserei-Ztg.* 26, 109-10(1929).—Oblique mech. charging produces large variations in the compn. and temp. of the gas in the front and rear of the furnace. Mech. charging, despite its advantages, at present appears to be inferior to hand charging. Each of two cupolas was equipped with an oblique charging device, a sketch of which is given. The cross sections of the smelting zone were 1.2 m. and 0.8-1.0 m. in diam.; the cupolas were charged 35-45 times daily; the daily capacities were 900 and 600 kg. of iron; coke addns. varied from 8 to 15%. Twenty runs were made on each cupola to det. the effect of oblique charging. In each run the following data were taken: coke addn., blast pressure, and temp. and analysis of gas withdrawn from the front and rear of the furnace.

JOHN W. W. SULLIVAN

Changes in carbon during cupola furnace fusions. H. PINSL. *Giesserei-Ztg.* 26, 1293-1301(1928).—Studies are made on the effect of fusing in cupola furnaces with or without a forehearth, and in a Schürmann furnace, and of varying conditions of charge, coke and blast on the C content of the melt. In the cupola furnace with a forehearth, the desired C lowering (between 2.6 and 2.8%) may be obtained by properly increasing the amt. of Fe charged, and decreasing the coke. The C content is lowered further, but easily, rather than by difficultly, fused materials. The results are less certain and less favorable in cupola furnaces without a forehearth, and in Schürmann furnaces. In these the steel must be in the most easily fusible form to give a low C content. The C cannot be lowered below 3% by doubling the quantity of blast, or the Fe charged, or by reducing by the use of smaller scrap. A general discussion of the changing of the C content in cupola furnace fusions is given.

J. BALOGH

The question of carbonizing of steel chips in the cupola furnace. MARTIN MIELAU. *Giesserei-Ztg.* 26, 182-3(1929).—A theoretical paper in which the carbonizing of steel chips is considered generally. It is maintained that the degree of carbonizing is different in different furnaces. In fusing the steel it must be considered as fundamental that the furnace is suitably constructed, the passage through is hotter, the tapping time is kept correct and the chips are chosen suitably. Osann's rule for calc. the charge mixts. does not hold here in every case.

J. BALOGH

Magnesite or dolomite for basic bottoms. MICHAEL KARNAUKHOV. *Iron Furnace and Steel Plant* 17, 545-7(1929).—Directions are given for building and repairing open-hearth steel furnace bottoms with burned magnesite, and a comparison of costs is made between magnesite and dolomite for this purpose. Suitable compn. and proper burning temp. are very important in obtaining high-grade magnesite for furnace bottoms. The results of an investigation of the mineralogical compn. of magnesite bricks are included.

JOHNS SCHAE

Studies of the Lancashire process. GUNNAR VINELL. *Jernkontoret* 82, 131-42(1927).—The paper gives the results of exams. covering temp., slag, the course of the process and the Lancashire iron produced, together with photographs of slags and Lancashire iron. The slags are mainly FeO and Fe₂O₃, evolved in ferrous silicate. The SiO₂ content of the slags is less than 11%. During the melting down Fe, Si, Mn and P are quickly oxidized. The sepn. of P depends on the temp. At low temp. the slag can contain more P. The slag content of Lancashire iron varies generally from 0.6 to 1%. The total Mn and Si content of the iron is contained in that slag. P in some degree may reduce FeO during the cooling of the iron. The brittleness of Lancashire iron is largely caused by badly decarburized parts. A. DE SMIT

Quality cast iron, difficulties in its production and new manufacturing processes. LAUCKA. *Giesserei-Ztg.* 26, 104-6(1929).—This is a survey of making cast iron in the cupola, elec. furnace and rotary furnace.

JOHN W. W. SULLIVAN

Some factors in the production of sound gray-iron castings. R. W. KIEHL AND KURT S. CLOW. James B. Clow & Sons, Chicago, Ill. *Am. Foundrymen's Assoc. Preprint* No. 29-7, 163-63(1929).—Scientific control of foundry methods is advantageous and does not involve unwarranted expense. For efficient production, castings should be designed for economical and uniform distribution of metal, angle draft, straight parting lines, and means for holding and venting cores. Tensile and permeability tests are very useful on all mold materials, and may be made readily on the same specimen by a method illustrated. The fineness, fusion conc. and moisture content are also detd. on all sand. The strength of sand molds is increased by proper

moisture content, increasing clay content up to 20%, smaller and non-uniform grain-size, more intense mixing and ramming, and longer, slower drying. Permeability varies directly as the square of the grain diam., and is not greatly improved by drying. The blowability value, or gas pressure generated when molten Fe is poured on the permeability specimen, may be detd. with a device described, and should be below 10 g. for safe avoidance of scabby surfaces and gas pockets. Venting is important, and pouring in green sand must be rapid enough to develop ferrostatic pressure faster than mold pressure. Defects of metallurgical origin may be due to CO gas produced on mixing FeO with C in the metal, the oxide generally being formed in pouring. Pouring temps. should not be too high, the atm. in the mold should be reducing, and the Fe exposed to air as little as possible. The pouring basin should be so designed as to sep. the dirt from the metal entering the gate.

GEO. F. COMSTOCK

The production of cast-steel anvils. HEINRICH KREUTZ VON SCHEELÉ. *Giesserei-Ztg.* 26, 15-6(1929).—There is described briefly the manuf. of cast-steel smith anvils, weighing 30 to 80 kg., from steel melted in the basic elec. furnace and of the following analysis: C 0.52-0.65%, Mn 0.70-1.10, Si 0.30-0.40, P 0.04 max., S 0.04 max.

JOHN W. W. SULLIVAN

Lead poisoning in bronze foundries. FRANK G. PEDLEY AND GORDON SPROULE. *Montreal General Hosp. Can. Med. Assoc. J.* 19, 566-71(1928).—Bronze frequently contains Pb. In the melting operation a temp. is reached high enough to cause considerable volatilization. The volatility of Pb from bronze at the temp. of treatment for casting (2100° F.) is about 0.020 g. per sq. in. of surface per min. Ten cases of Pb poisoning under such conditions are reported.

A. T. CAMERON

Cobalt magnet steel. P. H. BRACE. *Elec. J.* 26, 111-21(1929).—Co-steels with addns. of W, Mo, Cr or preferably of both W and Cr are good permanent magnets. The additions reduce the rate of pptn. and crystn. of C. A max. energy product is obtained from alloy of Fe 57, Co 35, Cr 4, W 2, and C 0.9%. The costs of constituents are tabulated showing that high cost of Co limits its practical use to app. demanding special magnetic material such as the multiple element portable oscillograph. The precautions required for manuf. and treatment of these steels and their properties are described.

M. MCMAHON

The new (welding) burner made of light metal. ANON. *Apparatebau* 41, 55-6(1929).—Description of the "Griesogen" welding torch

J. H. MOORE

The temperature distribution in the acetylene welding flame. F. HENNING AND C. TINGWALDT. *Z. Ver. deut. Ing.* 72, 1828-30(1928); cf. *C. A.* 23, 1350.—In addn. to measuring the spatial distribution of the temp., H. and T. found that the maximum temp. was lowered 40° with 20% excess of O and 60° with 7% excess of acetylene.

F. D. ROSSINI

What is dross in the galvanizing pot? WALLACE G. IMHOFF. *Iron Age* 123, 536-8(1929).—Dross varies from 8 to 50%. The av. is 12 to 20%. Dross is a Zn-Fe alloy. Its compn. varies with temp. and quantities of Zn and Fe present. Zn will dissolve Fe to form a satd. soln.; then the addition of more Fe causes the sepn. of the Zn-Fe alloy crystals. This dross settles to the bottom of the pot. The satn. point is reached when more than 0.1% Fe is dissolved at a certain temp. At a higher temp. dross is dry and sandy while low-temp. dross is wet and metallic. The av. dross contains 3.8% Fe, 0.2% Pb and 96% Zn. Following are 6 sources of Fe in order of their importance: (1) pickling solns., (2) overheating Zn, (3) steel base, (4) Fe corrosion products, (5) material dropped in the pot, (6) Zn used. Probably 50 to 70% of dross produced is caused by pickling solns. From 788° to 860° F. the action of molten Zn on Fe is very slight. From 860° to 900° this action is accelerated, while at 900° it becomes violent.

H. C. PARISH

Absorption of gases by metals. A. SIEVERTS. *Z. Metallkunde* 21, 37-46(1929).—S. discusses the mechanism of absorption for H_2 , N_2 , SO_2 , H_2 , and inert gases in various metals and alloys, both isobars and isotherms being plotted. In an appendix numerical data are given in tables for the systems Ag- CH_4 , Cu- SO_2 , Fe- N_2 , CO- H_2 , Fe- H_2 , Ni- H_2 , Cu- H_2 , Ag- H_2 , Pt- H_2 , Pd- H_2 , the soly. of the gases being expressed in mg. of gas per 100 g. of metal, atoms of gas (or mols. of SO_2) per 10,000 atoms of metal, and vols. of gas per unit vol. of metal.

H. STORITZ

Investigation of gases in metals. W. HESSENBRUCH. *Z. Metallkunde* 21, 46-57(1929); cf. *C. A.* 22, 2625.—H. discusses the significance of impurities, the manner in which gases are held, and various methods for the detn. of gas in metals, with a description of app. melting in vacuum is given as the most important method, and the results of a few gas detns. by this method for Cu, Ni, Al, Zn and Fe are included. In

refined Cu at 1250° the gas content ranged from 0.73 to 2.72 cc. per 100 g. of metal, SO₂ predominating (33-61% by vol.), while in electrolytic Cu the gas content was 7.98 cc./100 g., H content being 39.5% by vol. Ni at 1470° contained much higher gas content (113-803 cc./100 g.), electrolytic Ni, however, showing about the same quantity as electrolytic Cu (7.88 cc./100 g.). Detns. on Sn showed that as the metal is heated from 20° to 1350° the gas given off contains about 60% CO, 15% CO₂ and 25% H₂, while the gas given off while the temp. is held at 1350° contains about 25% CO and 68% H₂. In one sample 8.24 cc./100 g. is evolved between 20° and 1350° and 4.00 cc./100 g. at 1350°.

H. STOERTZ

New dilatometric investigations. MAX HAAS. *Z. Metallkunde* 21, 58-63 (1929).—Comparative curves show the resemblance between the results obtained with the *new mech. differential dilatometer* of Chevenard and the *optical differential dilatometer*. Dilatometer curves of various technically important alloys are given, with special attention to Al-Si, Al-Cu and Cu-Be alloys as well as *laulil* and *elektron*.

H. STOERTZ

The properties of fused metals and alloys and their significance for the casting process. F. SAUERWALD. *Giesserei* Z. 16, 49-55 (1929).—The exptl. results of S and his co-workers are summarized.

J. BALOZIAN

Fatigue phenomena, with special reference to single crystals. I. HERBERT J. GOUGH. *J. Royal Soc. Arts* 76, 1025-44 (1928). A brief historical survey of early fatigue expts. is followed by a description of the machines used at the Natl. Phys. Lab. for applying cycles of direct, bending and torsional stresses. Typical endurance test data are given for C and alloy steels, cast Fe, cast steel, Al, Cu, Ni, Mg, duralumin, brass, bronze, Monel and Mg alloys. Tests made at room temp. as to the effect of frequency upon the fatigue limit show that no appreciable speed effect exists up to frequencies of about 7000 cycles per min. It is concluded from data showing the values of the limiting range of stress with various mean stresses on some ferrous and non-ferrous alloys, that there is no general relation for metals between the safe range of stress and the mean stress of the cycle. II. *Ibid* 1045-62. Exptl. results are cited showing the effects of sudden discontinuities of section, and of small surface defects on endurance limit. From the results of many fatigue tests at elevated temps. and the general behavior of these metals under prolonged statical loading at the same temp., it appears that the existence of a fatigue range at elevated temp. still remains an uncertainty, and that the lengthy endurance observed under high ranges of rapidly applied stress are probably really due to a "time" or "delayed creeping" phenomenon. III. *Ibid* 1065-81. The importance of the effect which environment may exert on the fatigue resistance of metals is shown by the expts. of Haigh, Lehmann, McAlpin and Moore. The work of Stanton and Bairstow on impact fatigue tests of steel is discussed to show that the ratio of the endurance limit to the impact fatigue limit for these materials varies but little and that no relation exists between the ordinary impact and the impact-fatigue value. IV. *Ibid* 1085-1114. As a result of the work of Bairstow on steel and that of several investigators of the Natl. Phys. Lab. on Ni-Cp and Armco FP, the cyclic stress-strain relationships during a fatigue test can be summarized, briefly, in 3 distinct stages, as follows: (1) during the first stage of the test relatively large unclosed loops are observed whose widths tend to diminish with subsequent cycles; (2) during the second stage the loop may maintain a const. width, or may slowly increase or decrease; (3) during the third stage of the test the rate of increase of permanent set and of cyclical permanent set usually increases and fracture results. Changes in the microstructure of steel, Armco Fe and Cu, under fatigue stress, are described and illustrated by photomicrographs. V. *Ibid* 1117-42. The work of other investigators on the static deformation of single metallic crystals is summarized before the behavior of single crystals of Al under fatigue stressing is considered. It is shown that the safe range of stress on a crystal of Al is a state not of "primitive" but of "acquired" elasticity, as with an aggregate. The change in shape of a crystal of Al subjected to reversed direct stresses showed that the crystal had deformed by a process of single shear on one set of planes in a particular direction, the plane of shear being in exact agreement with the plane containing the traces of the slip planes, thus proving that slip bands really represent the traces of gliding planes by which deformation proceeds. The mechanism of deformation under static, fatigue and impact stressing is proved to be of the same nature. The hardening of single crystals of Al, when deformed plastically, so as to be able to resist further cycles of stress without further deformation, is found to be a real effect and not due to stress redistribution. Slip on one plane results in a mass hardening of the material. Fatigue failure is recognized as a special case of the general problem of the cohesion of matter, and the main problems concerning it will be solved when a more complete under-

standing is obtained of 3 main phenomena, viz., the cause of the low initial strength of crystals and the mechanism and consequences of slip and strain hardening.

Choice of materials for steam-turbine blading. E. A. KRAFT. *Elektrotechnik und Maschinenbau* 46, 301-5(1928). Five % Ni steel and stainless steel are the materials which can be used in the blades.

DOWNES SCHAAP

Attempts to improve the resistance of steel blading by surface treatment were not satisfactory. Zn, lacquer, enamel, Cr and Ni were tried, but all the coatings were eroded away. At present, stainless steel is the best material to use, though it is probably not the final answer. A binding wire which is soldered on to long blades to stiffen their edges presented soldering difficulties, since stainless steel must not be heated over 800°, and the soldering cannot be done well at much lower temps. Good work depends on nice temp. control, and much of the responsibility rests on the solderer. As it is impracticable to measure the temp. of each individual blade while the soldering is being done, a comparison method is used. A blade like those being soldered is maintained at the proper temp. by accurate instruments, and the workman matches its color against that of the piece he is soldering. To get accurate matching the work is done in a dark room. Perfect work can be turned out by this method. Other soldering involving costly steels is conducted in accurately controlled elec. resistance furnaces, with H passing through to avoid oxidation.

BENJAMIN MILLER

Metals for blades of the modern steam turbine. A. BODMER. *Chaleur et ind.* 9, 163-81, 239-44(1928), cf. C. A. 22, 3385. Brass (72% Cu, 28% Zn, Pb trace) usually resists the chem. action of impure steam but its mech. resistance is too low over 200°. However, as it can be given any profile, its use has been extensive. With the increase in power of the turbine and in peripheral speed, better metals have been desired. Ni and Ni alloys of about 50% Cu, 10% Ni and 40% Cu-15% Ni have been used. As with brass, the resistance falls as the temp. rises. 80% Cu-15% Ni can stand 350° and this alloy is used for low and medium pressures. 65% Ni-28% Cu is good up to 300°, but does not resist erosion very well. Monel metal is hardly better than brass under high operating conditions. Iron-Ni alloys (25-36% Ni) although resistant to oxidation, rapidly give way under the action of steam. Steel with 5% Ni is the best metal at present. If the steam is pure, turbine-vane corrosion can be avoided, but if salts, etc., are present, corrosion is certain. Erosion is more difficult to avoid than corrosion. The higher the steam temp., other conditions being the same, the less is the corrosion. To prolong the life of the blades, these were coated with difficultly oxidizable metals, but the coating itself eroded. Electrically deposited Cr was no better. Steels with low Ni content but high in Cr have given no better results. Various stainless steels have been tried, they become fragile and undergo oxidation in due course. Alloys with high Ni and Cr contents (A. T. V. metal) are best of all. Their resistance to oxidation and erosion is very good even with high-temp. steam. Numerous photographs illustrate pitting, corrosion, erosion, fracture and failure of turbine blades.

S. L. B. ETHERTON

Some experiences in sand control. E. F. WILSON. Jefferson Union Co., Lockport, N. Y. *Am. Foundrymen's Assoc.* (preprint) No. 29 8, 183-98(1929).—The vibratory test of sand with water in a bottle was unsatisfactory. Permeability varied linearly with clay content up to 10%. The permeability when hot may be less than when cold, or even neg. if the sand contains org. matter coal or water. The time element is important in regard to hot permeability. The pressure of gases from the sand must be low by the time the metal solidifies, to avoid porous castings. Too sudden gas evolution from damp strong sand causes sand-holes, appearing like slag, in the metal. In addn. to standard sand-testing methods, a clay detn. by vol., and a compaction test, are advocated. Facing sand especially should be tested regularly. Addns. of new sand should be as small as possible without reducing the green strength. Moisture should be as low as is compatible with good workability, and clay content barely high enough to permit low moisture. Sea-coal in the sand is useful to provide a reducing atm. at the surface of the casting, so that FeO is not formed there to cause adherence of the sand. Dry strength of the sand is important, but if too high cracked castings result. The correct gating is related to sand condition. Mulling of old sand without clay increases the bond strength by exposing fresh absorbent material below the surface of the grains. Screening of old sand before mulling is advantageous.

G. F. C.

Baking practice for oil-sand cores. H. L. CAMPBELL. Univ. of Mich. *Am. Foundrymen's Assoc.* (preprint) No. 29-13, 289-94(1929).—In baking cores made of sand, water and linseed oil, the temp. must first be raised high enough to evap. the water. During the evapn. period the temp. of the cores did not rise much, but afterward hardening was produced by oxidation of the oil at 175° to 230°. Gases must be removed rapidly from the oven, and an oxidizing atm. maintained, for efficient hardening. As the baking temp. was increased, the time of treatment needed became less. The strength was lower after baking too long, or at too high temp. At the higher temps., the time of treatment must be more accurately controlled. No damage resulted from placing these cores directly in ovens at the max. baking temp. G. F. C.

Shrinkage in white cast iron. H. A. SCHWARTZ. Natl. Malleable and Steel Castings Co., Cleveland, O. *Am. Foundrymen's Assoc.* (preprint) No. 29-10, 205-34 (1929).—The type of shrinkage forming porous spots in white cast Fe is discussed, and the complexity of the subject is emphasized. The freezing of a sphere of ideal metal with uniform phys. characteristics at all temps., resulting in a central cavity, is described. The presence of temp. gradients in the casting, and of differences in cooling rates, explains the occurrence of shrinkage. Thus if cooling is much delayed, shrinkage is reduced. A higher coeff. of expansion for liquid as compared with solid Fe increases shrinkage, but expansion in freezing as in gray Fe decreases it. The d. of liquid cast Fe varies linearly with temp., but the rate of change is a function of the Si content between 0.5 and 4% Si. The d. of white Fe varies linearly with the C content; at the f. p. it is 1.0043 times the value at room temp. The solid Fe may be more or less dense than the liquid, depending on the Si content. Previous work on the change of vol. during freezing is also reviewed, a contraction of 1.4 to 3.6% being indicated for white Fe. Tests were made by means of spheres 2.5 in. in diam., cast from a small gate, so as to freeze quickly and allow the shrinkage to be detd. from the d. of the casting as a whole. One expt. showed the voids in metal poured hot to be 1.67%, and poured cold, 1.30%, 4 tests of each being in good agreement. Further tests are reported on metal with different Si and C contents, 2.53% C and 1425° pouring temp. giving the lowest percentage of voids. The errors involved in sp. vol. detns. are discussed. Specimens from 5 foundries were tested, and a formula was derived as follows: sp. vol. = $0.126491 + 0.001074 C + 0.000534 Si$, allowing the sp. vol. to be calcd. from the C and Si contents with as good av. accuracy as from a d. detn., or better than 0.1%. Other factors than the C and Si contents, however, have a marked influence on the shrinkage. Smaller spheres are recommended for further work. GEO. F. COMSTOCK

Practical aspects of white-fracture malleable. D. P. FORBES. Rockford North western Malleable Corp., Rockford, Ill. *Am. Foundrymen's Assoc.* (preprint) No. 29-22, 397-404(1929).—By "white-fracture" malleable is meant malleable Fe of good ductility and machinability, with no combined C, but breaking with a white cryst. fracture, caused by intercryst. sepn. The grain boundaries are weaker than the ferrite grains. Most occurrences were in Fe contg. over 1.1% Si and 0.2% P, annealed at a max. temp. over 850°, and cooled slowly to below 540°. Heating to 450° and quenching, as in galvanizing, very often caused the "white fracture," and oxidation or slow heating in melting had the same tendency. Heating to 650° and rapid cooling corrected the tendency toward "white fracture." Metal exhibiting this defect showed a constituent different from ferrite along the grain boundaries, and this may be a P compound. More research on the subject is required. GEO. F. COMSTOCK

Controlling the atmosphere in malleable annealing ovens. W. F. GRAHAM. Ohio Brass Co., Mansfield, O. *Am. Foundrymen's Assoc.* (preprint) No. 29-14, 205-204 (1929).—In a well-insulated furnace for annealing malleable Fe, fired by powdered coal in the usual way, it was impossible to maintain a neutral atm. during the high temp. holding period without having a higher temp. near the burner than at the front of the furnace, as excess air was required to distribute the heat uniformly. To remedy this condition, some of the waste gases were returned to the burner. This resulted in less than 1% O in the furnace atm., uniform temp. at both ends of the furnace, and annealed Fe of good quality. The mechanism adopted is illustrated. No saving of fuel is claimed. G. F. C.

Properties of cast iron of interest to the metallurgist, founder and engineer. SUB-COMMITTEE ON RESEARCH OF THE COMMITTEE ON GRAY CAST IRON, JAS. T. MAC-KENZIE, et al. *Am. Foundrymen's Assoc.* (preprint) No. 29-17, 331-42(1929). A list of properties, classified as "causative," "formative," and "effective," of cast Fe is presented in great detail. The causative properties are chem. compn. and phys. constitution. The formative properties are those affecting the making of castings and

condition of the finished metal. The effective properties are peculiarly of interest to the engineer. Methods of test for most properties listed are discussed very briefly. The present method of detn. of combined C by difference is unsatisfactory. Tension, impact, and fatigue tests are worthy of study. Resilience is a useful property for evaluating cast Fe.

GEO. F. COMSTOCK

Remarks on the work of D. Hanson: "The properties of silicon-carbon-iron alloys and a new theory of cast iron." ERICH SCHEIL. *Giesserei Z.* 15, 1086-8(1928).—The basic assumption of Hanson (*C. A.* 22, 4432), which lacks exptl. support, that equil. exists between graphite and cementite and that the double diagram of Heyn and Charpy contradicts the phase rule, is not acceptable. Numerous investigations are cited to support the contention that cementite is unstable. If this takes up only a small quantity of the third substance in solid soln, then it is most probably an unstable phase in ternary compds. At all experimentally obtainable pressures cementite is stable.

J. BALOZIAN

The mechanical properties of deoxidized cast iron. PETER BARDENHEUER AND KARL L. ZEYEN. Kaiser Wilhelm Inst. Eisenforschung, Düsseldorf. *Giesserei Z.* 15, 1124-8(1928).—The deoxidation of cast Fe with ferro-Ti, and the effects of this, S and P on cast Fe are studied. The no. of fusions is insufficient to give final conclusions on the removal of O from cast Fe with ferro-Ti. It is shown that on addn. of 0.25% Ti there is an increase in the C content. The tensile properties of cast Fe are made slightly worse by Ti, but the elongation of annealed chill castings is improved. With S addn. up to 0.27% an unfavorable influence on the mech. properties of cast Fe could not be detected, its effect being less than with ordinary cast Fe, however. In cast Fe contg. 0.3% P the bending and tensile strengths are max. With increase in P the sagging and impact strength decrease uniformly, while the hardness and brittleness increase.

J. BALOZIAN

High-test cast iron. R. P. LEMOINE. *Am. Foundrymen's Assoc.* (preprint) No. 29-12, 250 88(1929).—A graphical representation of the constitution of cast Fe is discussed. The best mech. properties are attained when the Fe is composed only of graphite and pearlite, with the lowest total C. Free cementite is less detrimental than free ferrite. The cooling speed must be controlled to get equally good properties in different thicknesses of section. The Si content has somewhat the same influence as the cooling speed, but it also tends to diminish the C content of pearlite, so that under certain conditions increased Si giving more graphite does not involve the formation of ferrite. With low total C and high Si, the effect of cooling speed is diminished, giving uniformity of structure in all sections, and high strength. The French practice in making semi-steel shells during the war is reviewed. The Lanz and Thyssen-Emmel processes, based on the pearlite-graphite structure, are not considered novel, or practical for varied work. The use of expensive alloys in cast Fe is not necessary for high mech. strength. Elec. melting is useful for the chem. improvement of poor raw materials, and for refining the graphite, possibly by allowing kish to float out at high temp. Steel scrap is the best base for elec. furnace charges, which can readily be brought by addns. to any desired compn. The cost may be reduced by using a cupola for melting, and refining electrically. In this duplex practice, the cupola product should be as near the correct C content as possible, to save current consumption. To obtain a low-C cast Fe from the cupola, melting of steel scrap must be hastened by high air-pressure with only 12 to 14% coke, so that the fused drops passing the tuyères contain only 2% C. The use of a bottom receiver is an advantage to raise the temp., and the absorption of too much C in the receiver is best prevented by replacing some of the coke in it with brick fragments. Low-C Fe made in this way from rusty scrap may be wild and oxidized, but with ample Si it should be sufficiently fluid and quiet. Losses of Si through the cupola are lessened with an acid slag. High-Si steel scrap and high-Si pig Fe in the charge, are useful, pig Fe contg. 2.7% C and 4% Si is practical and convenient, but addns. of ferro-Si may be resorted to. The quality of such cast Fe is between that of semi-steel and elec. cast Fe, and its cost is not excessive.

GEO. F. COMSTOCK

High-test gray cast iron. European developments. EDWARD E. MARBAKER. Whiting Corp., Harvey, Ill. *Am. Foundrymen's Assoc.* (preprint) No. 29-23, 405-16 (1929).—The work of Goarens in 1906 showed that for max. strength, cast Fe should have a pearlitic structure, with fine and evenly distributed graphite. Cast Fe made with steel addns. to decrease the C content is best melted in the elec. furnace. According to Wüst, the C should be 2.2 to 3%, with Si 1.2 to 2.2%, and Mn 1%. The Lanz process, involving the use of low-Si Fe in heated molds, is described. It is complicated, but gives excellent results. By superheating the molten Fe above 1500°,

Piwowsky and Hanemann showed that the graphite is made finer, and uniform structures are attained. The high temp. may be obtained in the cupola, by oil or high blast pressure (Corsalli process). Schüz proposed the use of the graphite eutectic, contg. 3.6% C and 3.3% Si, cast in chills, giving high strength and stability. Meehanite is made by adding Ca silicide in the ladle, with 2.2 to 2.7% C and 1 to 1.8% Si. Deschene's process is purely mech., involving jolting the molten Fe to dissolve C completely, and eliminate gas and slag. Mitinsky and Osann are quoted as advocating the use of eutectic cast Fe for high-strength castings. In a pure alloy, this would contain 4.3% C; but with 2% Si and 1% P, the eutectic contains 3.33% C. Kish or primary graphite crystals should be avoided; then with C not over the eutectic percentage, highest gray Fe is obtained. All the processes involve the above principle. The eutectic alloys do not pipe; there is no segregation and min. shrinkage. G. F. C.

The influence of carbon, manganese and silicon on the growth of cast iron. O. BAUER and K. SIPP. *Giesserei* Z 15, 1018 26(1928). The influence of Mn (0.5-1.5%), Si (0.5-3.0%) and C (2.5-3.5%) on the growth of cast Fe was investigated. The rods were annealed at 450° (4 × 40 hrs.), 650° (4 × 10 hrs.) and 850° (4 × 10 hrs.) in an electrically heated muffle furnace, and the growth was detd. by the change in length before and after the annealing. The effect of compn. increases with temp., being most evident at 850°. Si favors the growth of cast Fe, this being slight with low Si even at 850°. The influence of Mn is considerably less favorable than that of Si, the growth decreasing with increase in Mn. C causes practically no change, its influence being of no importance with high Si or Mn. With high Si and low Mn, the action of the latter in increasing growth is aided considerably by C. *Ibid* 1047 60. —Microscopic investigation showed that at 450° the amt. of ferrite increased slightly with high Si; Mn, C and low Si are without effect on the structure at this temp. At 650° and 850° the structure is greatly influenced by these elements, even with shorter annealing. With low Si, at these temps., the pearlite becomes granular, and the graphite flakes become larger and denser. With high Si there is a large increase in the amt. of ferrite. Mn behaves similarly to the "growth" expts., while C produces only a slight change in the structure. Specimens annealed at 850° in contrast to those at 450° and 650° show sharply bordered zones. Here cementite (free or in pearlite) does not sep. out, but C from the solid soln. appears. Numerous photomicro. and photomicrographs are given. J. BALOZIAN.

Comparative tests on the mechanical characteristics of cast steel at elevated temperatures. ANTON POMP. *Stahl u. Eisen* 48, 1321 30(1928). The work was undertaken to obtain information on the behavior of cast steel at elevated temp. so as to lay the foundation for the development of specifications for cast steel used at high temp. and pressure. Test pieces were prepd. from 8 Siemens Martin steels, 1 dec. and 7 Bessemer steels. The analyses and histories of the samples are given in the form of a table. Tests were carried out at 20°, 100°, 200°, 300°, 400° and 500°. The test pieces were heated up to 200° in an oil bath, above that in a bath consisting of equal parts of KNO₃ and NaNO₃. Elongation was measured with the Martens junior instrument. The elastic limit decreased linearly with increase of temp. The yield point shows a similar curve, except that the values for the higher temps. are not quite as low as those of the limit of elasticity. The values at high temp. are between 42 and 67% of the original values, the highest values being for Mn steels (0.85-0.1% Mn) from 3 Bessemer samples; the one with the lowest S and P content shows the lowest yield point, 12.5 kg./sq. mm. With increasing temp. the tensile strength at first decreases, then increases; it shows a max. between 200° and 300°, which may be higher or lower than the original value, after that it decreases to a point 45-68% of the original value at 500°. The least reduction was 60-61%, obtained with high Mn steel. The elongation and reduction in area show a min. between 200° and 300°, followed by a rapid increase. The curves of the impact strength show great variations in their form, but all have a max. between 100° and 300°. The impact strength values depend on the size of the test piece and its place in the casting. J. A. SHERMAN.

Alloy cast steels. DAVID ZUNGE. *Silver Steel Casting Co., Milwaukee, Wis. Am. Foundrymen's Assoc.* (preprint) No. 29-20, 361-84(1929). Only machinable alloy cast steels of high phys. properties are discussed. Cr produces a hard carbide, retards the austenite transformation, and refines the grain of cast steel. Ni also retards the transformation, and hardens the ferrite. Mn acts in both ways, improving the properties of pearlitic steels. V is a scavenger, but also forms double carbides, increasing the yield point without loss of ductility. Mo acts with other alloys to improve the ease and stability of hardening. V, or 1.2 to 1.6% Mn, are the alloys most used in castings which are heat-treated only by the usual simple anneal. Av. phys. properties

of these steels are tabulated. Compression tests of cylinders are illustrated to show the superior ductility and strength of the Mn steel over ordinary C steel. Quenching and drawing improved the phys. properties of the Mn steel as compared with the usual normalizing. Cr up to 1% has improved the abrasion resistance of steel castings. Ni up to 1.5% is generally added with Cr, and the properties are shown to be superior to those of the Cr steel after any heat-treatment. The Cr-Ni steel was better than the Mn-C steel when hardened to high Brinell value, but when normalized, at lower hardness, the latter had better ductility. Mo up to 0.35% imparts air-hardening properties to Cr-Ni cast steel. Intricate shapes may thus be air-quenched and drawn to develop over 200,000 lbs. per sq. in. tensile strength with 10% elongation. Phys. properties of this steel with C contents from 0.28 to 0.42%, and drawing temps. from 370° to 840° are tabulated. Even when drawn at 540° the hardness was 430 Brinell. In yield point and impact resistance this Mo steel was especially superior to the other alloy steels. Photomicrographs show that when normalized and drawn at 680°, the Mn-C steel showed marked ferrite sepn, while the Ni-Cr-Mo steel showed none, and the Ni-Cr had an intermediate structure. The high-alloy steels are more expensive than the alloy cost alone would warrant, because of difficulties in handling. The importance of other factors than chem. compn. is emphasized. G. F. C.

Nature of martensite. N. SELVAKOV. Physico-Tech. Lab., Leningrad. *Nature* 123, 204-5 (1929).—Three transition points, viz., 100°, 235° and 300°, exist in the tempering of quenched steel. X-ray studies show that tetragonal martensite disappears at 100° and according to Honda this is a transformation from a tetragonal to a cubic lattice. S. assumes that in the tetragonal martensite the positions of the C atoms are fixed at the centers of those faces which are perpendicular to the tetragonal axes, while in the case of the cubic lattice the positions of the C atoms are not fixed, some replacing Fe atoms in the lattice and some being situated at the centers of the faces. These irregularities in position give a continuous variation of lattice parameter and account for the decrease in the intensity of the spectral lines, but not for their broadening.

W. W. STIFLER

Relative safety of mild- and high-tensile alloyed steels under alternating and pulsating stresses. B. P. HAIGH. *Chemistry and Industry* 48, 23-30 (1929).—A wide variety of tests and expts. with alternating and pulsating stresses and the conditions under which fatigue cracking may be a source of danger are described. It is shown that the relation between the fatigue strength and yield point of mild steel is such that fatigue cracking is necessarily uncommon in mild steel with ordinary conditions of loading. In high tensile steels the relation between the 2 kinds of strength is often such that fatigue cracking is more frequent. The article constitutes a rather complete though brief treatment of fatigue for the engineer.

ROBERT F. MEHL

The elastic limit of steel at elevated temperature. F. KORBER. *Stahl u. Eisen* 49, 273-7 (1929).—The results obtained by K. Schleip and P. Fischer (cf. *Kruppsche Monatshefte* 6, 185 (1925)), Urbanzyk (cf. *C. A.* 22, 1940) and Korber and Pomp (cf. *C. A.* 22, 2536) are tabulated and the ratio $(\sigma_0/1T^\circ)/(\sigma_R/20^\circ)$ is called ρ where $\sigma_{0.2}$ is the stress corresponding to a permanent deformation of 0.2%, for various temps. (T° between 20° and 500°, for the steel samples tested, and σ_R is the tensile strength of the same steel at 20°. The same ratio was calcd. for 12 melts of steel: 3 C (0.12-0.53%) Siemens-Martin; 2 high-Mn (0.74-0.85%) steel samples (one Siemens-Martin, the other an elec. steel); 3 high-Mn (0.77-1.07%) Bessemer; 2 Si (0.84-0.92%), 2 Ni (1.05-2.08%) steel samples (the last 4 samples were from the Siemens Martin furnace). The values of this ratio for the various steel samples tested are at 20° between 0.54 and 0.68, at 100° between 0.43 and 0.66, at 200° between 0.41 and 0.59, at 300° between 0.33 and 0.51, at 400° between 0.21 and 0.43 and at 500° between 0.17 and 0.31. The ratio decreases only about 10% up to 200°, after that it decreases rapidly. While the exptl. results are not yet complete, deductions are made from the above figures for the construction of boiler plates operated at elevated temps.

J. A. SZILARD

Flocks in chromium steel. WALTER AICHHOLZER. *Stahl u. Eisen* 48, 1332-4 (1928).—Flocks are observed frequently in steels with 1-3% Cr. Steel specimens were investigated with 0.8-1.2% C, 1-3% Cr, 0.2-0.3% Si and Mn; the S and P contents were below 0.02%. In general more flocks are observed in tools made from large, than in those made from small blocks. The irregularities detected as flocks in the tools can be observed in specimens from the blocks before working, as fine hair fissures. The structure of the steel surrounding the fissures is not the normal structure, but shows patches richer in carbide. By proper heat treatment it was shown that these patches have different C and Cr contents than the rest of the steel. Thus, flocks consist of 2 constituents, A with about 1% C and 3% Cr (as intended), and B

a more highly alloyed steel with 2% C and 13% Cr. If the steel is hardened at 950°, it represents a considerable overheating of A, but is only the normal hardening temp. for B. Around the large carbide areas a structureless ground mass is visible, while the rest of the specimen shows a coarse martensitic structure. Tests showed that during hardening of a melt corresponding to A, its linear expansion is 0.135%, or 18 times as much as that of B, which is 0.0075%. The flocks are probably caused by internal stress, effective at higher temp. (pearlite transformation) than the hardening temp. The coarse crystalline, shiny appearance of the flocks cannot be explained by their chem. compn. according to which they should be of finer grain size than the surrounding normal structure. But, as just the opposite is true, flocks must represent hot cracks; this assumption was proved by breaking tests at red heat and room temp. J. A. S.

X-ray investigation of iron-nitrogen alloys. ATOMI ŌSAWA AND SHUJIRO IWAI-ZUMI. *Z. Krist.* 69, 26-34(1928). (English).—There are 2 compds. in the system Fe-N. Fe₃N is cubic, with $a = 3.86$ A. U. The calcd. d. is 6.57. Fe₂N is hexagonal; $a = 2.743$ A. U. and $c/a = 1.59$; calcd. d. = 5.02. The Fe atoms form a close-packed hexagonal lattice, with one N atom in each elementary parallelepiped. The mechanism of the change from the cubic to the hexagonal lattice is explained. The calcd. diameter of the N atom, 1.26 A. U., is in good agreement with the value of Bragg. L. S. R.

Hardness and magnetic properties of iron-copper alloys and their relation to the equilibrium diagram. A. KUSSMANN AND B. SCHARNOW. *Physik.-Techn. Reichsanstalt. Z. anorg. allgem. Chem.* 178, 317-24(1929).—The Rockwell hardness, magnetic satn., and coercive force in the system Fe-Cu was investigated. The hardness of the Fe-rich side of the diagram rises sharply, and in the heterogeneous range changes only slightly, whereas the coercive force rises even in the heterogeneous range because of contraction tensions. In a repetition of the work of Ishihara (*C. A.* 17, 719) the increase in soly. of Cu in Fe is shown by quenching expts., in which both hardness and coercive force were measured. The soly. increase above the A₂ point was detd. by both methods. Contrary to the work of Ishihara no irregular change in the coercive force or hardness was found at the A₂ transformation. ROBERT F. MEHL

Brass and special brasses. W. WUNDER. *Z. Ver. deut. Ing.* 73, 165-8(1929), cf. *C. A.* 22, 209(1928).—The following topics concerning brass are discussed: early history, equil. diagram, specifications for German standard brasses with their fabrication and industrial uses, recrystn. of α -brass, residual strains after forming and their removal by annealing. The normal tensile strength of 28,000 lbs./sq. in. for cast brass and 57,000 lbs./sq. in. for worked and annealed brass may be increased to 57,000 lbs./sq. in. for cast special brass and 90,000 lbs./sq. in. for worked and annealed special brass. The metals added to brass to increase its strength may be divided into two classes: those which displace the limit of the α -field toward the Zn side, e. g., Ni and those which displace it toward the Cu side, e. g., the remaining elements, Mn, Al, Zn, Mg, Si, Pb, Fe. The Zn equivalents of the elements are Al + 2, Sn + 2, Mg + 2, Si + 10, Pb + 1, Fe + 0.9, Mn + 0.5, Ni - 1.4. With the addn. of several of these elements the apparent Zn content may be calcd. by the formula $B' = (B + 2q)/A$, ($A + B + 12q$) where B' is the apparent Zn content, B is the true Zn content, A is the Cu content, q is the quantity of added elements of Zn equivalents (l). Two rules apply: (1) The apparent Zn content may not rise above 45%, since above this the alloy becomes brittle. For hot forming without cracking the Zn content should be between 45 and 38%; for cold forming between 0 and 38%. (2) Ni does not impart brittleness in any proportion of metals. With addn. of Ni more of the other element may be added than without Ni. The special brasses are prepd. usually by the use of master alloys. They are better than the ordinary brasses in strength, hardness and corrosion resistance. Occasionally their color is an advantage. Compositions for 9 special brasses are given. ROBERT F. MEHL

The repair of cast aluminum parts by welding. H. REININGER. *Gießerei-Z.* 26, 125-31(1929).—The prepn. of the weld, autogenous welding app. and microstructure of the weld are illustrated. JOHN W. W. SULLIVAN

X-ray investigation of the system: lead-thallium. F. HALLA AND R. STAUBER. *Z. Krist.* 68, 299-330(1928).—Additional discussion of a previous article (*C. A.* 22, 2058). It is concluded that there is no symmetrical distribution of the Pb and Tl atoms. L. S. RAMSDELL

The preparation of bearing metals. WALTER VOIGT. *Giesserei* Z. 15, 6(1928) (1928).—General metallographic principles are applied to the prepn. of the 17% Pb, 6.8% Sn, 1.8% Ni alloy. J. BALDWIN

Antifriction metals. J. DAUTERANDES. *Chaleur et Ind.* 9, 418-4(1928).—The following precautions should be observed on pouring: (a) The melt should be very well mixed

(b) it should not remain undisturbed for any long period since particles of different densities and hardness may segregate; (c) the part about to receive the antifriction metal should be previously heated to about 400° F.

Survey of Cu-Sn alloys. GIESSEI-Zig. 20, 91-103(1929).—This is a survey of (I) pure Cu-Sn bronzes, (II) the influence of small quantities of other elements on Cu-Sn bronzes, (III) the influence of larger amounts of Zn, Pb and P on the mechanical properties of bearing bronzes, and (IV) the separate constituents of the bronze bearing metals. In tabular form the following data are presented: (1) ultimate strength, elastic limit, elongation, Brinell hardness, and Fremont impact strength of (a) pure Cu-Sn alloys, (b) Cu-Sn alloys contg. 0.04 and 0.62% Zn, (c) Cu-Sn alloy contg. a trace of P; the friction, temp., and degree of wear of (a) Cu-Sn alloys Pb free, and (b) contg. 4.82-31.32% Pb; (3) wearing out strength and elongation in 2 in. of Cu-Sn alloys contg. 0.37-0.86% P; and (4) wearing out strength, elastic limit, and elongation in 2 in. of Cu-Sn alloys contg. 1-3% Zn.

JOHN W. W. SULLIVAN

Physical properties of dental materials (gold alloys and accessory materials). R. L. COLEMAN. Bur. Standards, *Research Paper No. 32*, 867-938(1928).—Methods of testing the properties of the different materials were developed and a large no. of tests were made on representative com. products. The more important results of the investigation follow: (1) the mech. properties of many of the Au alloys can be markedly improved by suitable heat treatment; (2) the porosity prevalent in dental Au alloy castings can be minimized by changes in sprue design and the placing of a feeder of suitable size close to the pattern; (3) net linear casting shrinkage of an alloy, contg. 90% Au and 10% Cu was found to be approx. 1.25%; (4) the thermal expansions of 5 inlay pattern waxes were found to vary from 0.7 to 0.8% in linear dimensions over the temp. range of 25-40°; (5) the usual investment for inlay castings expands approx. 0.25% on setting; (6) the compressive strength of the investments studied were not affected by heating to temps between 200° and 800°, but cooling from these temps. resulted in a marked loss of strength; (7) the investments expanded 0.2 to 0.3% by heating to 250-300°, contracted when heated to 350-450° and expanded up to 1.0% or contracted as much as 0.5% depending on the investment when heated to 600°.

DOWNES SCHAAF

Resistance of iron-nickel-chromium alloys to corrosion by acids. NORMAN B. PILLING AND DONALD E. ACKERMAN. Am. Inst. Mining Met. Eng., *Tech. Publication No. 174*, 3-33(1929).—The effects of compn. of Fe-Ni-Cr alloys and heat treatment thereof on the resistance in acids were studied for alloys varying from 0 to 100% Ni, 0 to 30% Cr and 0 to 100% Fe. Tests were made in air-satd. solns. with test pieces wholly submerged and rotated. Discontinuous changes in soly. occur in the corrosion of Fe-Ni-Cr alloys. In non-oxidizing acids, if the Ni content is below a certain critical amount, Cr increases the rate of soln. and Ni decreases this rate; this critical content of Ni is about 13%. Alloys contg. more Ni corrode at const. rates independently of Cr or Fe contents. The rates depend upon p_H and acid radical but the crit. Ni content does not. The latter is independent of microstructure or lattice structure of the alloys, but heat treatment, without effect on either of these, shows a marked effect on the location of the limit of attack. In the soly. in HNO_3 the points at which passivity is attained depends upon Cr content only. The Cr content necessary is a function of HNO_3 concn. The soly. in H_2SO_4 is markedly influenced by the presence of dissolved salts necessitating a change in Cr content for protection. The observed effects are not compatible with Tammann's theory relating corrosion resistance to lattice structure, but are believed to agree with current views on the electrochemical nature of corrosion.

B. E. RORTHELI

Corrosion phenomena appearing in aluminum bronze, brass and copper tubes in practice. A. MARR AND E. BRENNKE. Bergakademie Clausthal. *Giesserei Z.* 15, 1128-33(1928); cf. C. A. 22, 4099.—A metallographic study of the corrosion of Al bronze, brass and Cu condenser tubes under actual conditions, using neutral alkali chloride liquors (after operation for 4 weeks), river H_2O (after 15 years) and alkali chloride and $MgSO_4$ liquors, resp. In the Al-bronze tube the corrosion occurs in the grain boundaries and the slip bands (principally here), while in the brass tube it occurs in the grain boundaries of the brass. In both cases the influence of grain size is not great. These tubes should be annealed after cold working to remove internal strains. In the brass tube, Cu is present in the salt deposit and on the metal surface in consequence of the soln. of the brass and the subsequent pptn. of the Cu from the soln. It is recommended that these tubes should consist of homogeneous α -brass, and not of ($\alpha + \beta$)-brass. Here, tinning is of advantage only when it is uniform; otherwise it is a disadvantage.

The presence of seams and furrows in the structure of Cu tubes is explained by the corroding action of the salt particles, steam, and air.

J. BALOZIAN

The reaction limit of magnesium-cadmium alloys and their potential-concentration curve. C. KRÖGER. Univ. Göttingen. *Z. anorg. allgem. Chem.* 179, 27-48(1929).—The reaction of these alloys with MeOH, with which Mg reacts rapidly with the evolution of H, and toward which Cd is inert, was investigated. Cast and rolled (unannealed) plates gave a reaction limit at about $\frac{2}{3}$ mol. fraction Cd, but showed some reaction up to $\frac{4}{5}$ mol. fraction Cd. A 23-hour anneal in this range (55-73% Cd by wt.) at 430° sharpened the reaction limit and eliminated the reaction above $\frac{2}{3}$ mol. fraction Cd. Attack by EtI, contg. a little free I, gave exactly similar results. Calculation of the protective action of the insol. Cd atoms on the sol. Mg atoms on the basis of random distribution of the protective atoms in the space lattice gives a higher protective value than that actually found. By assuming, however, a regular distribution of Cd atoms, the reaction limit obtained becomes explicable. The electrode potential of these alloys was measured in a cell $\text{Cd} | \text{N MgSO}_4 | \text{Cd, Mg}$, and in each case a potential-time curve taken. Alloys with less than 50% Cd showed a rapid decrease in potential in the first 20 hrs., then remained const. for 25 hrs. and then again fell to more "noble" values. With more than 50% Cd the potential at first rose, in the course of 3 hrs. reached a max. and then behaved as before. The potential concn. curve showed a close correlation with the structure of the alloy (C. A. 21, 3528). The effect of band membranes upon the potential is discussed in detail.

ROBERT F. MEHL

Corrosion of metals as affected by stress, time and number of cycles. D. J. McADAM, JR. Am. Inst. Mining Met. Eng. *Tech. Publications No. 175*, 57 pp (1929). This paper discusses the interrelationship of stress, time and number of cycles in causing penetration of metals under corrosion. The resultant fatigue limit is used as a criterion of the depth and sharpness of corrosion pitting (cf. C. A. 22, 1318). Four variables and their interrelationship are considered. The paper first discusses the relationship between corrosion-stress and resultant fatigue limit with the other two variables held const. The form of the graph, representing this relationship, indicates local strengthening of the metal at the bottoms of the corrosion pits. The field of investigation is then extended to include stresses between zero and the endurance limit. By widening the range of corrosion-stresses it was then possible to extend the range of cycle frequencies so as to include frequencies as low as 5 cycles per hr. "Constant-damage" graphs were then developed so as to represent the stress-time cycle relationship with resultant fatigue limit held const. Const. damage graphs are discussed as various views of const. damage surfaces. Const. damage graphs and surfaces on a logarithmic scale are the most useful method of representing the relationship among the four variables. Graphs for alloy steels varying widely in comp. and physical properties are discussed. From the constant damage graphs, other graphs and surfaces are developed to represent the damage (due to cyclic stress) in excess of the amount of damage that would be caused by stressless corrosion alone.

B. E. ROETHLI

The direct determination of metal corrosion by the measurement of current density and its significance. F. TÖDT. *Z. Ver. deut. Zuckerind.* 79, 1-10(1929). A method is given whereby the corrosion of metals may be read off directly on a current indicator. The exptl. and theoretical bases for this method of measuring corrosion are discussed. The practical applications of the new process are presented in a general way and then specifically in relation to the sugar industry.

E. A. FINGER

Surface films protect metals against corrosion. P. N. SPELLER. *Chem. Met. Eng.* 36, 85-7(1929).—Various methods of corrosion protection are cited as being due to the formation of surface films. The passivity of Cr and Cr-Ni steels is attributed to the presence of a highly resistant surface film rather than to lowered soln. pressure.

B. E. ROETHLI

Laboratory corrosion tests of mild steel, with special reference to ship plate. HENRY S. RAWDON. *Bur. Standards J. Research* 2, 431-40(1929).—Total immersion and alternate wet and dry tests of ship plate and mild steels varying in Cu content up to 0.60% showed no significant differences in the corrodibilities of Cu bearing steels. The corrosion rate was uniform for all steels in submerged corrosion. The corrosion product was flocculent and easy to remove. The rate of attack in the wet and dry method was greater but the rate decreased because of the formation of a dense hard scale which was difficultly removable. It is believed that differences in service conditions will account satisfactorily for the alleged difference in corrosion behavior of these steels.

B. E. ROETHLI

Introductory address at the annual meeting of the Imperial Committee for Metal

Protection and report on the scientific work of the committee for the fiscal year. E. MAASS. *Korrosion Metallschutz* 5, 1-7(1929).—Metals placed in corroding solns. of various salts under conditions of total immersion in absence of air, total immersion in presence of air, partial immersion (liquid aerated), total immersion (soln. stirred) and total immersion (temp. 95-100°) corroded at relative rates for the order named of 1, 3, 3, 5 and 8.6. Ferrous metals were attacked most strongly while Cu, high-Cu brass, bronzes and special Fe alloys were attacked relatively slightly. Solid salts in an atm. having the same humidity as that outdoors attacked all metals to some degree. Ferrous metals were uniformly attacked, while the attack on resistant metals and special Fe-Cr-Ni alloys was slight, but of a pitting character. The order of corrosiveness of the salts investigated decreased for the following materials: $MgCl_2$, carnallite, rock salt, NaCl, KCl and $MgSO_4$. The corrodibility of Al in acid solns. is decreased by annealing and rolling. Paint pigments, when dusted on Fe electrodes, changed the electrode potentials as follows: Minium +0.01v. to -0.015v., lead peroxide +0.033v., lead oxide +0.047v., Pb (powder) -0.167v. (+ indicating more noble). Upon exposure the plates dusted with minium and Pb showed rust spots after 14 days while the other plates showed none. The protective influence of Pb oxide may be attributed to the formation of an alk. product upon immersion.

B. E. ROETHELI

• **Galvanized pipes - metal coatings.** BATTIGE. *Apparatebau* 41, 53-5(1929).—B. claims that galvanizing gives no permanent protection against corrosion in H_2O pipes.

J. H. MOORE

Turbine corrosion and degasification. G. PARIS. *Chaleur et ind.* 9, 188-90 (1928).—Corrosion may occur (a) on the blade or (b) on the edge of the blade and may be rust or just erosion by water droplets. Corrosion may result from faulty working, or from matter entrained in the steam. Among entrained matter may be (a) oxygen, (b) water, (c) solids. Among means for reducing corrosion are (1) to make the blades of difficultly oxidizable metal, (2) degasification of the water, physically or chemically. A line diagram shows a water purifier and deaerator system.

S. L. B. ETHERTON

Resistance of a few steels to chemical action in relation to carbon, nickel and chromium contents. FRITZ SCHMITZ. *Z. Metallkunde* 21, 64-5(1929).—The types of metal examd. were unalloyed steel with increasing C content (0.06-0.92%), steel with Cr content between 8 and 18% and Ni content increasing from 0.5 to 62%, and steel with high Cr content (15-18%) and relatively low Ni content, but with very high C content (1.33-1.84%). The reagents studied were cond. H_2O , sea water, HNO_3 (dil. and concd.), H_2SO_4 , H_2SO_4 (dil. and concd.), HCl (dil. and concd.), 80% acetic acid, citric acid (1:2), concd. NH_4OH , KOH (1:2), and aqua regia, and the results are expressed in terms of % loss in wt. after 180 hrs. treatment. In unalloyed steel the effect of increasing C content is increased protective action against sea water, cond. water, H_2SO_4 , dil. or concd. HCl and oxidizing gases, but action by dil. H_2SO_4 is more severe with high C content. The influence of increased Ni content in a Cr-Ni steel is at first an increase in attack with dil. H_2SO_4 , followed by reduction in attack. In cond. and sea water, dil. HNO_3 , citric acid, NH_4OH and KOH, increase in Ni content has very little effect. In HNO_3 and KOH, these Ni-Cr steels can be regarded as completely passive. The results show that in oxidizing agents the protective action is due solely to Cr, while in dil. H_2SO_4 and dil. and concd. HCl, the Ni is the constituent which exerts a protective action. Thus an alloy with 0.42% Ni and 14.5% Cr shows 38.5% loss in dil. H_2SO_4 , while an alloy contg. 54.4% Ni and 12.4% Cr shows only 0.193% loss in the same reagent.

Concentrating ores by flotation. A. H. FISCHER (to D. Guggenheim, M. Guggenheim, S. R. Guggenheim, S. Guggenheim, J. K. MacGowan and E. A. C. Smith (trading as Guggenheim Bros.)). Brit. 296,270, Dec. 29, 1927. Flotation sepn. is effected in the presence of frothing agents such as cresylic acid or pine oil together with a water repellent org. compd. contg. a thiocarbonyl group, e. g., ethoxythiocarbonyl ethoxy carbonyl sulfide (which is formed by allowing ethyl chlorocarbonate to react with an aq. soln. of K ethylxanthate at a temp. below 20° and dilg. with water and fractionally distg. to sepn. from xanthic anhydride). Cf. *C. A.* 22, 2136.

Recovering platinum and other precious metals from ferruginous sulfide ores. S. C. SMITH. Brit. 296,744, June 7, 1927. The ore is treated to remove silica and the resulting mat, comprising principally Cu sulfide, is treated with acid to dissolve Fe and Ni; the leached mat is then roasted and the product is treated with acid to dissolve most of the Cu and any remaining Fe and Ni. The residue is then treated for the extn. of Pt (suitably by the process described in Brit. 289,220) (*C. A.* 23, 2000). The H₂S liberated in leaching the mat may be used to ppt. Cu and Ni from the liquor obtained by leaching the roasted residue, or for conversion into H₂SO₄ for use in the leaching.

Pumping system for mining gold, etc., in placers by direct leaching with cyanide solutions, etc. B. STOKES. Brit. 296,813, June 9, 1927.

Roasting spathic iron ore and like ores. ANTON APOLD and HANS FLEISCHER. Ger. 472,194, June 25, 1926. See Austrian 100,862 (*C. A.* 23, 1009).

Jigs for treating tin ores or other materials. T. V. O'HARE. Brit. 296,889, June 26, 1927. Structural features.

Precipitating copper from solutions. I. G. FARBENIND, A. G. Brit. 296,831, June 9, 1927. In pptg. Cu by use of iron, the soln. is agitated by means of a gas (e.g., SO₂ and O (suitably air contg. a small proportion of SO₂ or waste gases from a plant for making H₂SO₄ by the contact process)).

Treating copper ores. F. DIRTZSCH. Brit. 296,869, Sept. 26, 1927. Oxidized Cu ores are leached with a soln. of HCl, the soln. is reduced by SO₂ during or after the leaching operation, Cu is pptd. by H₂S and the residual liquor (contg. free HCl) is either used in a further leaching operation or, when its H₂SO₄ content is sufficiently high, is used to generate H₂S for use in the process from a sulfide such as a mixt. of Ca and ferrous sulfides obtained by melting lime 3 with pyrites 10 parts. In treating sulfide ores, the SO₂ produced in the preliminary roasting of the ore is utilized in other stages of the process. Cf. *C. A.* 23, 1860.

Treating iron ore. VEREINIGTE STAHLWERKE A.-G. Brit. 297,096, Sept. 16, 1927. Fe ore is treated with Cl or HCl vapor, to form and volatilize FeCl₃, and the FeCl₃ is then reduced to Fe (suitably by H). The chlorination is preferably effected under 10 atm. pressure, and with alterations of pressure. Brit. 297,097 specifies the use, as chlorinating agents, of compds. such as NH₄Cl which can be used in a cyclic process alone or with other compds. such as Cl, HCl or MgCl₂. HCl liberated in the reduction of the FeCl₃ may be combined with NH₃ liberated in the chlorination stage, thus regenerating NH₄Cl.

Iron from ores. VEREINIGTE STAHLWERKE A.-G. Fr. 647,530, Jan. 22, 1928. Fe is prepd. from its ores by chlorination to FeCl₃ by means of Cl or substance contg. it and direct reduction to Fe by H. The chlorination is carried out under a pressure of 10 atm. and the reduction under pressure in the presence of a catalyst such as spongy Fe. If the ore contains As or Sb, it is first treated with HCl at temps. of about 100°. Cf. *C. A.* 23, 590.

Removing arsenic from ores. METALLGES. A.-G. and A. G. PAUL PALÉN. Ger. 472,475, Dec. 22, 1926. Arsenic is driven off as As_2S_3 from ores contg. As and S by heating the ores in an upright muffle in which the ore continuously descends while fresh ore is fed in from above. The As_2S_3 is withdrawn through a side pipe.

Centrifugal apparatus for casting metals. A. POSSENTI and C. SCORZA. Brit. 296,902, Sept. 28, 1927. Structural features.

Apparatus for centrifugal casting of pipe or similar metal articles. CARL PARDUN and PAUL VOETTER (to Centrifugal Pipe Corp.). U. S. 1,708,849, April 9.

Casting and rolling copper. ANACONDA COPPER MINING CO. Brit. 296,746, June 7, 1927. A cake of Cu for subsequent rolling into sheets is formed by casting endwise in a tapered mold which may also be formed of Cu.

Apparatus for subjecting castings or forgings to magnetic tests to detect irregularities of structure of the metal. ALLGEMEINE ELEKTRICITÄTS GES. (to International General Electric Co.). Brit. 296,303, Aug. 27, 1927.

Foundry molding apparatus. W. LEWIS. Brit. 296,568, Sept. 21, 1927. Mech. features.

Ingot mold. EMIL GATHMANN. Ger. 472,048, Dec. 25, 1924.

Semi-permanent sectional molds for casting cylinders of internal-combustion engines, etc. C. CROSTHWAITE and W. E. STYLES. Brit. 296,863, July 22, 1927. Structural features.

Blast furnace. AUGUST KUSEMANN. Ger. 471,884, May 4, 1927. An open cooling chest is provided.

Cupola furnace. WOLFGANG MANN. Ger. 471,870, Sept. 3, 1926. On the forehearth, one or more flat surfaces are built with gratings which hold back the slag and ore, but allow the molten metal to flow through and enable the gases to be blown in.

Furnace for heating metals such as steel scrap by a flame centrally projected into an annular mass of the metal. LYLE C. LOSBOUGH. U. S. 1,708,509, April 9. Structural features.

Rotary inclined chemical furnace suitable for smelting lead or zinc ore. LUIGI TOCCO and MICHELE LANDI (to Soc. "Le Four Chimique Rotatif"). U. S. 1,708,526, April 9.

Furnace and cyanide pot for use in heat treatment. WILLIAM J. MERTEN (to Westinghouse Elec. & Mfg. Co.). U. S. 1,707,313, April 2. A liquid seal is arranged to prevent creeping of molten material over the support on which the edge of a cyanide pot is mounted.

Heat-treating furnace including a pot or crucible for a fused cyanide bath. JAMES C. WOODSON (to Westinghouse Elec. & Mfg. Co.). U. S. 1,707,294 5, April 2. A seal or shield is provided for preventing material from the crucible creeping to its outer surface. Cf. C. A. 23, 2145.

Superposed hearth furnace for roasting ores. METALLGES. A.-G. (formerly Metallbank und metallurgische Ges. A.-G.). Brit. 297,053, Sept. 13, 1927. Structural features.

Apparatus for injecting powdered material through the tuyères of blast furnaces so as to modify instantaneously the nature of the slag. SOC. ANON. JOHN COCKERILL. Belg. 352,300, July 31, 1928. Mechan. features.

Porous slag. WILLY KINBERG. Fr. 647,573, Jan. 21, 1928. A porous slag is obtained by adding to the molten slag, particularly from blast furnaces, substances such as sand, charcoal or powd. stone which will form vapors at high temps.

Converter for transforming cast iron into steel or pure iron. LA CARBONISATION SOC. GÉNÉRALE D'EXPLOITATION DES CARBONES. Fr. 647,014, Jan. 12, 1928.

Malleable iron having a black fracture. C. E. KLUJTMANS. Belg. 351,246, June 30, 1928. A charge consisting of steel scrap, residues from previous melts, ferro-Si and ferro-Mn is melted in a cupola. Charcoal with very low S content is used as fuel. The castings are packed cold in sand and waste ore, and heat-treated in an annealing furnace. Cf. C. A. 23, 1863.

Malleable cast iron. LESLIE H. MARSHALL (to Ohio Brass Co.). U. S. 1,707,529, April 2. Iron is annealed in the hard iron condition by subjecting the iron to heating for a sufficient time to change the combined C into free or graphitic C, and the annealed iron is then stabilized by quenching it before its temp. has been allowed to drop below that which will cause the iron to be embrittled. A chart of times and temperatures is given.

Annealable white-iron casting. ALFRED L. BORGENHOLD (to General Motors Research Corp.). U. S. 1,707,753, April 2. An annealable white-iron casting free from flake graphite comprises Fe, C, a graphitizing agent such as Si capable of promoting

the formation of temper C during annealing and a suitable metallic ingredient such as Mo, V, Ni or Cu which serves to obstruct the formation of flake graphite during solidification of the casting.

Iron sponge. S. E. SIEURIN. Brit. 296,235, Dec. 6, 1927. In producing iron sponge by reducing pulverized briquetted ore embedded in a solid reducing agent intimately mixed with lime or magnesia, at a temp. below the m. p. of the metal and in the absence of air or other gas, an excess of the reducing agent, such as C, is used, such that free C is present in the ash when the reduction is completed. The cooling of the product is accelerated to prevent recombination of S with the reduced metal sponge.

Pearlitic iron with nodular graphite. C. KLUJTMANS. Belg. 351,110, June 20, 1928. Steel trimmings, residues from previous melts, ferro-Si and ferro-Mn are melted in an ordinary cupola provided with tuyères through which air is blown under a pressure depending on the diam. of the cupola. The castings are subjected to heat treatment depending on their thickness.

Iron salts. BRÜCK, KRETSCHEL & Co. and OTTO KIPPE. Fr. 647,497, Jan. 19, 1928. Fe salts for briquetting Fe ores or blast-furnace dust are obtained by dissolving hammer or rolling slag or Fe bloom in HCl.

Rendering iron and steel non-oxidizable. F. DEGRÖOTE. Belg. 351,800, July 27, 1928. After cleaning, the metal is immersed in a bath contg. an acid and a salt of an acid of which one or more of the acid functions has been neutralized by an alkali or alk.-earth metal or a metal of the Pb group, and also an inert oxide of a metal or of a metalloid.

Steel. FREDERICK C. LANGENBERG and MARCUS A. GROSSMANN. Fr. 647,541, Jan. 28, 1928. See U. S. 1,695,594 (C. A. 23, 812).

Steel. GRANULAR IRON CO. Fr. 647,587, Jan. 21, 1928. In the production of Fe "produced in the solid state" a sufficient proportion of oxide of Fe is retained in reduced to prevent liberation of P in the elementary state in the ultimate manufacture of steel from the Fe.

Purifying metals. HENRY HARRIS. Fr. 647,632, Jan. 24, 1928. Cu is removed from metals or alloys by submitting the molten metal or alloy to the action of sulfur gases yielding S in the absence of air, and removing the slag of sulfide formed. Reducing agents such as resin may be added to the melt.

Zinc. HENRY E. COLEY. Fr. 647,768, Jan. 18, 1928. Zn is obtained from its ores or oxide by preheating the ore, etc., and passing it at a temp. between 700° and 1100° through a zone where it comes in contact with a hydrocarbon fed in through a cooled tube, so that decomposition of the hydrocarbon occurs only in contact with the ore, which is thereby reduced.

Apparatus (with a rotary drum having internal pockets) for producing liquid zinc from blue powder. FILIP THAKALONEN. U. S. 1,708,403, April 9.

Thin nickel flakes. EDMUND BREUNING (to Electric Storage Battery Co.). U. S. 1,707,217, April 2. Sheets are formed with alternating layers of Cu and Ni and the Cu is dissolved in a soln. of ferric salts such as $Fe_2(SO_4)_3$ free from Cl and acid. $FeCl_3$ sulfate and air accelerate dissolving of the Cu.

Metals and alloys. HERBERT VACUUMSCHMELZE A.-G. and WILHELM P. Ger. 471,503, Sept. 7, 1926. C-free metals and alloys are prepd. by subjecting the C-contg. materials to the action of MgO in vacuo.

Chilled-roll alloy. FRANK D. TAGGART. U. S. 1,707,232, April 2. A chilled-roll alloy comprises Fe together with C 3.5, Cr 1.75, V 0.20, Si 1.0 and Mn 0.50, with small quantities of S and P.

Alloys for use as solders. AMERICAN MACHINE & FOUNDRY CO. Brit. 296,586, Oct. 20, 1927. Pb contg. 0.05-0.1% Pb phosphide, with or without about 0.5% of a "brightening metal" such as Al, Sb, Sn or Zn, is used for soldering.

Aluminum alloy. TH. GOLDSCHMIDT A.-G. Fr. 647,407, Jan. 17, 1928. An Al alloy contains Mg, Si 1.5 (± 0.2), Cu 1.2 (± 0.2), Ti 0.5 (± 0.2) and Mn 0.8 (± 0.2). This alloy, after mech. treatment, is heated to 520-550°, rapidly cooled and cooled at a higher temp. The elasticity is increased by exposing it to a temp. of 110-120° for 6-24 hrs., the tenacity by exposing it to a temp. of 130-145° for 6-24 hrs., or for a particular tenacity to a temp. of 145-160°. To obtain elasticity and resistance to corrosion the aging is not carried out until 6-48 hrs. after the initial heating and cooling.

Silver alloys. I. G. FARMENING A.-G. Brit. 297,105, June 30, 1927. Silver alloys are formed contg. up to 22% of a mixt. of Al and one or more of the elements Ti, Mg, Zn, As, Sb, Bi, Sn or Si; or contains up to 22% of a mixt. of Al and Mn and at least one of the elements As, Bi, Sb, Mg or Ti, with or without Zn, Sn or Si.

Lead and lead alloys. H. HARRIS. Brit. 296,557, Sept. 3, 1927. In the purification of Pb or its alloys, the molten metal (at a temp. between its m. p. and redness) is brought into contact with a reagent comprising molten caustic alkali, with or without NaCl or other fusible chloride) to which has been added one or more of the oxides of Pb or other metals having less affinity for O than that of the impurities to be removed. The oxides may be supplied in the form of a dross. Fractional and successive removal of different impurities may be effected, such as successive removal of As and Sn from antimonial Pb.

Iron alloys containing chromium and nickel. ELECTRO METALLURGICAL CO. Brit. 297,045, June 9, 1927. Various articles are formed by welding rolled members of an Fe alloy contg. Cr 15-40, Ni 2-15, Si 0.7-3.0%, Mn 0.7-3.0% and C not more than 1%.

Steel alloy. MAX BAEKE. Fr. 646,974, Jan. 11, 1928. A steel alloy particularly for tools contains C 0.6-1.5, Ni 0.5-3, W or V 1-5%.

Steel alloys. FRIED. KRUPP. A-G. Fr. 647,236, June 8, 1927. Steel alloys for the manuf. of articles hardened with N contain Si, Mn, Ni, Cr, Mo, W, V, Ti or Zr either singly or mixed 1-8, Al less than 0.5 and C up to 0.7%. If the content of Si, etc., lies between 4 and 8% the content of Al is preferably 0.5-2%.

High-phosphorus scale-resisting alloy steel. FRANK R. PALMER (to Carpenter Steel Co.). U. S. 1,707,364, April 2. An alloy steel which is suitable for use at high temps. contains C less than 1.50, P 0.05-0.50 and Cr 3-30%.

Apparatus for tempering ferromagnetic materials. EISEN- u. STAHLWERKE HORSCH and WILLY HEIDENHAIN. Fr. 647,296, Dec. 15, 1927.

Case-hardening. A. E. TAYLOR, H. W. BARTON and F. A. JONES. Brit. 297,163, June 25, 1927. A material for use in case-hardening mild steel or other ferrous metals comprises disintegrated dried or heat-treated doom palm nut, coquilla nut or apple nut, with or without corozo nut and BaCO_3 ; charcoal and Na_2CO_3 also may be added.

Apparatus for atomizing and spraying molten metals, etc. METALLISATOR BERLIN A-G. and E. GREISER. Brit. 296,546, Aug. 24, 1927. Structural features.

Metallization by spraying of parts of valveless motors. MINERVA MOTORS and J. DE JONG. Belg. 351,469, June 30, 1928. Light steel parts are sprayed with metals that are suitable for reducing friction to a min.

Apparatus for finishing metal sheets by rolling. SAMUEL E. DIESCHER (to S. Diescher & Sons). U. S. 1,708,411, April 9.

Preparing metal sheets for tinning. SAMUEL E. DIESCHER (to S. Diescher & Sons). U. S. 1,708,412, April 9. A pack of wet metal sheets after pickling is subjected to high pressure applied progressively from a mid-portion to the edges of the pack to remove water and assocd. chemicals remaining from the pickling operation.

Uniting metal bodies. CHARLES F. SHERWOOD. 1,708,193, April 9. In uniting metal bodies such as clips and flexible elec. conductors, a suitable metal powder, e. g., Cu, Sn, Pb and graphite, is placed between them and heated in a non-oxidizing atm. to effect union of the particles with each other and with the metal bodies to be united.

Rubber-lined metal tube. IRWIN F. KEPLER (to B. F. Goodrich Co.). U. S. 1,708,141, April 9. Mech. features.

Silvering. L. J. V. GRANIER. Brit. 296,667, Sept. 2, 1927. In silvering metals and alloys other than certain Sb alloys, AgCl is pptd. from a soln. of AgNO_3 by use of NaCl, the ppt. is washed and dissolved in Na thiosulfate soln. and NaHSO_4 soln. and whitening are added. The article to be silvered is wiped with a pad moistened with this product.

Coating iron sheets with aluminum. F. JORDAN. Brit. 296,474, June 1, 1927. Details of heating and rolling metal sheets or strips together are specified.

Protecting metal of electric conductors from chemical action of sulfur in insulating materials. F. KIRSCHNER and J. HESS. Brit. 297,161, June 23, 1927. Zn is used as a coating material for the conductor, preferably after a preliminary coating with Sn or a Sn alloy. A coating of Ni may also be applied before coating with Sn.

Apparatus for removing surplus spelter from galvanized articles by streams of air from blast nozzles. WAYNE RAWLEY and ORAND A. PLASKEY (to Blaw-Knox Co.). U. S. 1,707,770, April 2.

Mounting of electric cables to prevent corrosion. J. W. HOFMANN. Brit. 297,160, June 23, 1927. Parts of a clamp or tension mounting for an elec. cable which are in contact with the conductor are made of the same metal as the latter while other parts are made of iron or steel.

Rust preventing. Wm. H. COLZ. Fr. 647,314, Dec. 26, 1927. Fe and steel are

protected against rust by treating them with a soln. contg. phosphates of Al, Zn, Fe and Cr. Cf. C. A. 23, 138.

Electric welding. ERNEST LUNN (to Pullman Car and Mfg. Corp.). U. S. 1,707,405, April 2. Elec. current is applied at intervals of successively longer duration, in order to facilitate welding of "black stock" steel without preliminary picking or sand-blasting.

Electrode mounting for automatic electric welding apparatus. AUGUSTIN J. HAND (to Calif. Corrugated Culvert Co.). U. S. 1,707,433, April 2. Structural features.

Electrodes for arc welding. E. M. F. ELECTRIC CO. PROPRIETARY LTD. Brit. 296,509, June 28, 1927. Electrodes are provided with coatings contg. a substance which is decompd. in the arc to liberate H to protect the fused metal from oxidation and nitrogenization. A suitable coating mixt. comprises fluxes and slags and contains "vegetable black" or similar carbonaceous material and a hydrated Al silicate such as china clay, the combined water from which is liberated in the arc and is converted into H and CO. Various structural and other details are given. Cf. C. A. 23, 1612.

Arc-welding electrodes. COMPAGNIE FRANÇAISE POUR L'EXPLOITATION DES PROCÉDÉS THOMSON-HOUSTON. Fr. 647,002, Jan. 12, 1928. The electrodes are made by heating the wire forming the core in an alk. soln. contg. Fe_2O_3 , one or more Ca compds., e. g., CaO, and a small quantity of Na_2SiO_3 , until a thin homogeneous layer is formed. Cf. C. A. 23, 1106.

Welding cast iron. HENRY V. WILLE. U. S. 1,708,815, April 9. In producing a soft fusion weld on cast iron, there is added to the weld ferrous metal contg. 4-20% total C. Cf. C. A. 22, 1323.

Flux for welding and soldering aluminum and other metals. W. REUSS. Brit. 296,923, Nov. 10, 1927. H_3BO_3 or a mixt. of H_3BO_3 and borax is used with KOH or other free caustic alkali; e. g., an aq. soln. may be formed from equal quantities of borax, H_3BO_3 , and KOH. Cf. C. A. 23, 1100.

10—ORGANIC CHEMISTRY

CHAS. A. ROUILLER AND CLARENCE J. WEST

Inflammation of mixtures of the olefins and air in a closed spherical vessel. G. B. MAXWELL AND RICHARD V. WHEELER. Sheffield Univ. *J. Chem. Soc.* 1929, 245-51; cf. C. A. 22, 167.—Data are given for the inflammation of mixts. of C_2H_4 , C_3H_6 , and C_4H_8 and air, the mixts. initially at atm. pressure and room temp. and ignited by a secondary discharge at the center of a closed spherical vessel of bronze, the interior highly polished. As with the paraffins, there is with each olefin a marked displacement of the observed max. pressure mixt. from the theoretical mixt. for complete combustion toward excess of hydrocarbon. These displacements can only be attributed to the effects of dissociation, since the calcd. values, for which an allowance is made for dissociation, are similarly displaced. As with the paraffins, the close correspondence between the observed values for the max.-speed mixts. and the calcd. values for the max.-temp. mixts. shows that, for mixts. of a given combustible with air, flame temp. is the controlling factor in detg. the mean rate of development of pressure. C. J. WEST.

Some new tautomeric phenomena in the allylic series. CHARLES FRIEDEL. *Compt. rend.* 187, 1052-4 (1928).— $\text{CH}_2\text{CHCH}(\text{OH})\text{Et}$ (I) and $\text{EtCHCHCH}(\text{OH})\text{H}$ (II) are mesomeric at room temp. but at about 300° some transformation of I into II takes place. A pseudo-isomeric bromide corresponding to II is formed from I by action of PCl_5 , while the action of PCl_5 on I yields 2 different chlorides, $\text{CH}_2\text{CHCH}(\text{Cl})\text{Et}$, b. 93°, d^{20}_4 0.8966, n^{20}_D 1.4224, and $\text{CH}_2\text{CCH}(\text{Cl})\text{CH}_2\text{Et}$, b. 109.5°, d^{20}_4 0.8995, n^{20}_D 1.4146, resp. These chlorides are mesomeric and become desmotropic above 150°. After allowing them to react with NaOAc , only $\text{AcOCH}_2\text{CH}(\text{CH}_3)\text{CH}_2\text{Et}$ could be isolated while NaOEt with either chloride yields a mixt. of $\text{CH}_2\text{CHCH}(\text{OEt})\text{Et}$, b. 102°, d^{20}_4 0.8798, n^{20}_D 1.3996, and $\text{EtCHCH}(\text{OEt})\text{CH}_2\text{Et}$, b. 123°, d^{20}_4 0.7930, n^{20}_D 1.4009. A. L. HENRI.

Catalytic splitting off of alcohol from acetals (preparation of unsaturated ethers). FRITZ SIGMUND AND REINFRIED UCHMANN. Univ. Wien. *Monatsh.* 51, 234-52 (1920).— $\text{Me}(\text{CH}_2)_3\text{CH}(\text{OR})_2$, b. 203-5°, heated with a Ni catalyst, or with porous clay, splits off EtOH and gives amylinyl *Et ether*, b. 173-5°. Similarly, the di-*Pr* acetal gives 70% of amylinyl *Pr ether*, b. 184-7°. $\text{PhCH}_2\text{CH}(\text{OMe})_2$ gives β -methoxystyrene (36% yield); with brass turnings the reaction is incomplete at 400°. The di-*Pr* acetal

gives 70% of PhCH:CHOPr . MeCH(OEt) gives 60% of MeCH:CHOEt . PhC(OMe)Me gives 86% of PhC(OMe):CH_2 . $\text{PhC(OPr)}_2\text{Me}$ gives 97% of α -propoxystyrene, b. $214-9^\circ$ (cor.).

Allyl β -hydroxyethyl sulfide and derivatives. S. M. SHERLIN AND V. V. VASILEV-SKII. Moscow High Tech. *J. Russ. Phys.-Chem. Soc., Chem. Part* 60, 1629-32 (1928); *J. prakt. Chem.* 121, 173-6 (1929).—Allyl β -hydroxyethyl sulfide, $\text{HOCH}_2\text{CH}_2\text{SCH}_2\text{CH:CH}_2$, was prepd. thus: With uninterrupted stirring and strong cooling a concd. aq. soln. of 73 g. KOH was slowly poured into 87 g. crude allyl mercaptan. To the mercaptide thus obtained 104 g. $\text{ClCH}_2\text{CH}_2\text{OH}$ was cautiously added drop by drop with cooling. The mixt. was heated on a water bath till the emission of ethylene ceased. KCl pptd. and 2 liquid layers were formed, the upper presenting a light yellow oil and the lower a satd. aq. soln. of KCl. The reaction mixt. was dild. with H_2O to complete soln. of the KCl, the oil was sepd., dried with K_2CO_3 and fractionated *in vacuo*, the fraction b_{12-13} $87-95^\circ$ being refractionated. Thus 34.5 g. of the product was obtained, representing a 50% yield on the mercaptan. It is a colorless and almost odorless oil, b_{12} $90-2^\circ$, readily sol. in EtOH , Et_2O , almost insol. in H_2O . It rapidly decolorizes Br in cold CS_2 . Allyl β -chloroethyl sulfide.—Through a separatory funnel 30 g. PCl_5 was cautiously dropped into 52 g. of the β HO compd., after which the mixt. was heated 1 hr. on a water bath and, on cooling, poured into ice-water. An oil was formed which was sepd., washed with H_2O and dissolved in C_6H_6 . The C_6H_6 soln. was washed with 2% Na_2CO_3 until neutral, dried with CaCl_2 and, after evapn. of C_6H_6 , fractionated at 12-13 mm. taking the fraction b. $64-71^\circ$. After a refractionation, 27 g. of the product was obtained, the yield being 45%. It is a colorless liquid, b_{12} $67.5-69^\circ$, an unpleasant odor, insol. in H_2O , readily sol. in org. solvents. It slowly decolorizes Br in CS_2 .—*Acetoxyethyl allyl sulfide*.—Six g. Ac_2O and 1 drop H_2SO_4 were added with cooling to 5.3 g. of the HO compd., then the mixt. was heated 20 mins. on a water bath and the product obtained was fractionated, collecting the fraction b_{12-13} $93-7.5^\circ$ and distg. it again, this time taking the fraction b_{12} $94.5-96^\circ$; 3.5 g. of perfectly pure acetate was thus obtained. The same product can also be obtained thus: 10.5 g. of the β -Cl compd. is poured into a paste of 15 g. AgOAc and 22 cc. 86% EtOH and the mixt. is refluxed 10 hrs. on a water bath while agitating from time to time. The liquid is sepd. by suction from the AgCl formed, dried with CaCl_2 and fractionated. It is a colorless liquid with a fairly pleasant odor of fruit, insol. in H_2O , readily sol. in org. solvents. It instantly decolorizes Br in CS_2 . Gasparini and Savini's method of electrolytic oxidation (*Gazz. chim. ital.* 37, II, 437) had to be used to analyze the HO compd. and its acetate, as the attempt to analyze the latter by the Carius method provoked an unusually violent explosion. BERNARD NELSON

Action of acetylene on selenium. F. P. MAZZA AND L. SOLAZZO. Univ. Naples. *Rend. acad. sci. Napoli* 33 [3], 236-9 (1927).—Dry, pure HC CH reacted with finely powd. Se at $250-300^\circ$ with evolution of flames. A brown oil was formed and evolution of a gas (H_2Se) was noticed, which decompd. rapidly, giving a deposit of Se. The reaction product was extd. with EtOH . After evapn. of the EtOH the residue was subjected to fractional distn. The 1st fraction consisted of selenophene (I), reddish, b. $113-4^\circ$, while the selenophene obtained by Foa (*C. A.* 5, 693), b_{12-13} $147-8^\circ$. The 2nd fraction consisted of selenonaphthene (II), yellow crystals from $\text{PhH-Et}_2\text{O}$, m. $53-4^\circ$; picrate, golden yellow. II is probably formed by condensation of I with PhH , which latter may be formed from HC CH by polymerization. The H_2 liberated in this condensation combines with Se, giving rise to formation of H_2Se . G. S.

Esters of phosphoric acid. I. Phosphates of cetyl alcohol, cholesterol, chloroethyl alcohol and ethylene glycol. ROBERT H. A. PLIMMER AND WM. J. N. BURCH. St. Thomas' Hospital Med. School and Westminster School. *J. Chem. Soc.* 1929, 279-91.— POCl_3 (3.5 g.), added slowly to 5 g. cetyl alc. in CHCl_3 and heated 2 hrs. on the water bath, poured into water, neutralized with BaCO_3 and Ba(OH)_2 , the filtrate concd. and treated with EtOH , gives 60% (5.5 g.) of *Ba monoacetyl phosphate*, pale yellow, crystals with 1 H_2O ; dil. H_2SO_4 gives the free phosphate, m. 72° (Biehinger, *Ber.* 38, 3974 (1905)). Heating 9 g. POCl_3 and 25 g. cetyl alc. in CHCl_3 until HCl is no longer evolved and pouring into Ca(OH)_2 gives 5 g. *Ca monoacetyl phosphate*, and 10 g. (60%) of *diacetylphosphoryl chloride*, yellow, boiling the latter with Ba(OH)_2 for 10 hrs. gives *Ba diacetyl phosphate*, which is easily hydrolyzed by acid. Boiling cetyl alc. and POCl_3 in mol. proportions gives only cretine. POCl_3 (3 g.) gradually added to 5 g. cetyl alc. on the water bath gives *triacetyl phosphate*, m. 61° , also obtained by boiling an excess of the alc. with P_2O_5 in H_2O . POCl_3 (4.2 g.), slowly added to 12 g. cholesterol (I) in CHCl_3 , and after 24 hrs. poured into H_2O and neutralized with BaCO_3 and Ba(OH)_2 , gives a small yield of *Ba monocholesteryl phosphate*, crystg. with

4H₂O; dil. H₂SO₄ gives the *di-H deriv.*; the Pb and Ag salts are insol., the Cu and Na salts are sol. in H₂O. POCl₃ (2 g.) and 8 g. I, treated as above, give a very small yield of *Ba dicholesteryl phosphate*; the *di-II deriv.*, obtained with dil. H₂SO₄, could not be obtained by Euler and Bernton's method (C. A. 22, 89). *Tricholesteryl phosphate*, yellow, could not be freed from cholesteryl chloride. POCl₃ (15 g.) and 30 g. ClCH₂CH₂OH, after 24 hrs., give 3 cc. of *tri-β-chloroethyl phosphate*, b₅₅ 140°, d. 1.39, and 12 g. of a mixt. of Ba salts, from which was isolated *Ba β-hydroxyethyl phosphate* (II). Using 15 g. POCl₃ and 15 g. ClCH₂CH₂OH and heating 2 hrs. on the water bath, there results a mixt. of mono- and di-derivs., from which the *Ba δ-β-hydroxyethyl phosphate* is sepd. by crystn. from H₂O. ClCH₂CH₂OH (8.2 g.) in 40 cc. C₆H₅N at -20°, slowly added to 30.6 g. POCl₃ in 80 cc. C₆H₅N at -15°, gives 7 g. *Ba β-chloroethyl phosphate* (III), crystg. with 1 H₂O, decompg. 120°. III yields a *brucine salt*, crystg. with 4 H₂O, removing the brucine with NH₄OH and boiling with yellow PbO gives II. O₂POEt and ClCH₂CH₂OH give III. The action of yellow PbO or Ag₂O upon the trichloroethyl phosphate gives the *di-β-hydroxyethyl deriv.*; this also results from ClCH₂CH₂OH and Na₂PO₃; the Na salt crystals with 6 H₂O. (CH₃O)₂Na₂ and POCl₃ give very sol. products which may be salts of (CH₃O)₂POOH. The various esters of H₃PO₄ are completely hydrolyzed by dil. acid. The mono- and di-esters of the aliphatic alcohols with H₃PO₄ are not hydrolyzed and the tri-ester is hydrolyzed to the di-ester, by dil. alkali. All esters of PhOH with H₃PO₄ can be completely hydrolyzed by dil. alkali. II. The action of ethyl metaphosphate on alcohols, ammonia and some amino compounds. *Ibid* 292-300.—By the action of various alcs. on O₂POEt (I) there results a mixt. of esters of H₃PO₄ and usually a mixed ether, sometimes a simple ether. EtOH gives the mono- and di-Et esters; PrOH gives mono- and di-Pr and mono- and di-Et esters and Pr₂O; cetyl alc. gives the mono- and dicetyl and mono- and di-Et ester; and Et cetyl ether and dicetyl ether; PhOH gives the mono- and di-Ph and mono- and di-Et esters and EtOPh; cholesterol gives the mono-cholesteryl and -Et esters and Et cholesteryl ether. *Ba Et phosphate*, crystals with 1 H₂O; the *di-Et ester* is anhyd. 10 g. (I) give 10.9 and 4.5 g. of these esters, resp. I (11 g.) and 12 g. PrOH give 6 g. of the *di-Pr ester*, 11 g. di-Et ester and *Ba di-Pr pyrophosphate*, converted into *Ba Pr phosphate* by warming with dil. Ba(OH)₂. *Ba Ph phosphate*; *Ba di-Ph phosphate*, crystals with 4 H₂O. Tyrosine and I do not react. I and dry NH₃ in CHCl₃ appear to yield NH₄EtHPO₄. *di-NH₃ Et phosphate* results from the Ba salt and (NH₄)₂SO₄. *NH₃ Et phosphate* likewise results from the Ba salt and (NH₄)₂SO₄. I and NH₃ give apparently hydrazine *Et di H phosphate*, which yields with CuSO₄ hydrazine sulfate, blue, and EtCuPO₃. PhNHNH₂ gives a salt of itself and EtH₂PO₃. Alamine appears to give a salt with Et tri H pyrophosphate, which becomes a salt of Et di H phosphate on treatment with H₂O. *Guanidine di-Et pyrophosphate* results from I and guanidine carbonate in dry CHCl₃. C. J. WELSH.

Strength and volume relationships in organic linkages in molecules. F. E. HERTZ. Chem. Inst. Univ. Bonn. *Z. anorg. allgem. Chem.* 178, 292 (1929).—A study of the compds. formed when Ni(CN)₂ is combined with NH₃, MeNH₂, EtNH₂, PrNH₂, BuNH₂, Me₂N and Et₂NH. Stability was detd. by measuring the vapor pressures while analyses of the compds. gave the vol. relationships in their formation. R. C. ROBERTS.

A modified Curtius degradation. III. The degradation of saturated fatty acids and benzoic acid. C. NABGRI, LYDIA GRONTUCH AND P. LENDORFF. *Ber. chem. Ges.* 53, 1227-61 (1920); cf. C. A. 23, 113.—A flask fitted with a ground glass connected reflux condenser with a glass-stoppered side tube at the lower end which permits addition of NaN₃ (I) was used for the interaction of acid chlorides and I. The quality of I has a great influence on the rate and completeness of the reaction and it was found that I, prepd. by Thiele's method (cf. C. A. 2, 3315), was generally more active than that of other com. products. The rate of reaction is also greatly influenced by the quantity and kind of solvent; PhH appears to be the solvent of most general use; Et₂O cannot be used for aliphatic acids of low mol. wt. and for polybasic acids since the b. p. is below the temp. at which the azide is converted to the isocyanate and the reaction products are explosively unstable. *Heptadecylamine-HCl* (II) was prepd. by adding 1.5 g. I to 6 g. C₁₇H₃₅COCl (cf. Kraft and Bürger, *Ber.* 17, 1378 (1884); C. A. 22, 498). After warming for 2.5 hrs. nearly all of the N₂ was evolved, the mixt. was filtered from pptd. NaCl, washed with a small amt. of hot PhH, 10 cc. concd. HCl added to the filtrate, carbonate CO₂ warmed, the PhH removed by warming *in vacuo*; 5.4 g. II was sepd. by filtration and dried over KOH; recrystd. from abs. EtOH or by pptn. from EtOH with Et₂O at m. 188°. The *free base* (3.8 g.) was prepd. by treating 6 g. C₁₇H₃₅COCl with I in PhH as above, filtering the reaction product into a tubulated retort contg. 15 g. slaked lime.

then adding 15 g. more lime, closing the retort with a cork covered with Na silicate, distg. off the PhH and then distg. the base into a receiver protected from CO_2 with soda lime tube; at the end of the distn. the base is dissolved in ligroin, sepd. from H_2O , dried over KOH and then distd. over Na in an atm. of N_2 ; colorless crystals, m. 49° , were obtained. A 19% yield of *stearic heptadecylamide*, m. 88° , was obtained by interaction of 6 g. $\text{C}_{17}\text{H}_{35}\text{COCl}$ and 1.4 g. I in PhH, filtering, warming 1 hr. with glacial AcOH, removing PhH and AcOH by warming *in vacuo* and recrystg. the residue from EtOH; evapn. of the mother liquors gave 4.8 g. *acetic heptadecylamide* which was recrystd. from EtOH, then from ligroin and m. 62° . Similarly from palmitic acid, 80% *pentadecylamine*, m. 33.5° , b₇₆₀ 301° , 95.5% of its HCl salt, softens 164° and m. 199° , and 80% *acetic pentadecylamide*, m. 72° , were obtained. From lauric acid were obtained 80% *undecylamine-HCl* as colorless crystals which soften 180° and m. 190° , 71% *undecylamine*, m. $15-16^\circ$, and 76% *acetic undecylamide*, m. 48° , b₁₂ 192° . Isovaleric acid gave 71% *isobutylamine-HCl*, m. 164° , from which the free base was prepd., and 79% *acetic isobutylamide*, b. 227° . A 60% yield of $\text{MeNH}_2\cdot\text{HCl}$ was prepd. by adding 6 g. I to 6 g. AcCl in 20 cc. dry PhH, warming to $70-80^\circ$ until N_2 is evolved (cooling when the reaction becomes violent), adding 20 cc. concd. HCl with cooling, warming to $30-40^\circ$ until CO_2 is evolved, removing PhH by distn. *in vacuo*, drying the residue on a water bath and then at 110° , extg. with abs. EtOH and pptg. from EtOH with Et_2O . When 5 g. AcCl and 5 g. I in 50 cc. PhH are warmed to $65-75^\circ$ at such a rate that the N_2 is evolved in 20 mins. then treated with 30 cc. glacial AcOH, the PhH removed *in vacuo*, the residue distd., the distillate dissolved in Et_2O , treated with solid NaOH, filtered and fractionally distd., 72% of *acetic methylamide*, b₇₆₀ $202-4^\circ$, was obtained and from this a nearly theoretical yield of $\text{MeNH}_2\cdot\text{HCl}$ can be obtained by hydrolysis with HCl in a sealed tube. An 80% yield of *diphenylurea* was obtained by interaction of 3 g. BzCl and 1.5 g. I in PhH; when Et_2O replaced the PhH as the solvent 60-74% $(\text{PhNH})_2\text{CO}$, 17% BzOH and 4% PhNH_2 were obtained. A 75% yield of $\text{PhNH}_2\cdot\text{HCl}$ was obtained from BzCl and I in PhH in a manner similar to the prepn. of II. The prepn. of PhNHAc from BzCl and I in a manner similar to the prepn. of the other amides above gave only a 0.4% yield but when 10-15 cc. of glacial AcOH contg. 5% Ac_2O was used 90% of PhNHAc and 6% PhNHBz were obtained.

N. A. LANGE

Modification of the Curtius synthesis of primary amines. RICHARD H. F. MANSKE. Yale Univ. *J. Am. Chem. Soc.* 51, 1202-4 (1929).—It is suggested that the hydrolysis of alkylureas and urethans, when acid or alkali hydrolysis is impracticable, be accomplished by means of phthalic anhydride and subsequently with $\text{N}_2\text{H}_4\cdot\text{H}_2\text{O}$. Octamethylene-1,8-dimethylurethan (4 g.) and $\text{C}_6\text{H}_4(\text{CO})_2\text{O}$ (8 g.), heated at 230° for about 30 mins., give 7.4 g. of 1,8-diphthalimideoctane, m. 138° , hydrolysis gives octamethylenediamine. $\text{PhOCH}_2\text{CH}_2\text{CH}_2\text{CONHNH}_2$ from $\text{PhOCH}_2\text{CH}_2\text{CH}_2\text{CO}_2\text{Et}$ and $\text{N}_2\text{H}_4\cdot\text{H}_2\text{O}$, m. $81-2^\circ$, with NaNO_2 and HCl gives the azide which, heated with dil. AcOH, gives di- γ -phenoxypropylurea, m. 150° ; with $\text{C}_6\text{H}_4(\text{CO})_2\text{O}$ this yields γ -phenoxypropylphthalimide, m. 94° , hydrolyzed by $\text{N}_2\text{H}_4\cdot\text{H}_2\text{O}$ to $\text{PhOCH}_2\text{CH}_2\text{CH}_2\text{NH}_2$. β -[3-Indolylethyl]urea gives β -[3-indolylethyl]phthalimide, pale yellow, m. 164.5° ; hydrolysis with $\text{N}_2\text{H}_4\cdot\text{H}_2\text{O}$ gives tryptamine quant.

C. J. WEST

The influence of poles and polar linkings on the course pursued by elimination reactions. II. The mechanism of exhaustive methylation. CHRISTOPHER KELK INGOLD AND CHARLES CYRIL NORREY VASS. *J. Chem. Soc.* 1928, 3125-7; cf. C. A. 23, 2150.—The decompn. of quaternary NH_4 compds may occur along 2 lines: $\text{CHR}_1\text{R}_2\text{CR}_3\text{R}_4\text{NMe}_2\text{OH}$ gives $\text{CR}_1\text{R}_2\text{CR}_3\text{R}_4 + \text{NMe}_2 + \text{H}_2\text{O}$ (reaction A), or $\text{CHR}_1\text{R}_2\text{CR}_3\text{R}_4\text{NMe} + \text{MeOH}$ (reaction B). The following facts should favor B at the expense of A: R_1 and R_2 should have more influence than R_3 and R_4 ; when R_1 and R_2 increase, B should increase progressively until it reaches a const. value, when $\text{R}_1\text{R}_2\text{CH-}$ or any part thereof is branched, B should be greater than with the isomeric unbranched compd. These predictions have been verified by measuring the % olefins (reaction A) obtained when $\text{R}_3 = \text{R}_4 = \text{H}$, while R_1 varies. The results were: Et 95%; Pr 84%; Bu 79%; Am 77%; C_6H_{13} 76%; C_6H_{11} 74%; C_6H_9 75%. The const. value is thus 75%. The last prediction is verified by the fact that the value for Bu is 79% while for iso-Bu it is only 72%. III. The decomposition of dialkyl sulfones. GEOFFREY WILLIAM FENTON AND CHRISTOPHER KELK INGOLD. *Ibid* 3127-30.—Theory requires that dialkyl sulfones decomp., in a similar way to quaternary NH_4 hydroxides, into an olefin and an alkylsulfinic acid. It is experimentally found that Et_2SO , m. 71° , is decompd. by KOH at 200° into C_2H_4 and EtSO_2H . Ethyl octyl sulfone, m. 68° , prepd. by oxidizing the sulfide, b₁₀ $109-3^\circ$, with HNO_3 gives C_8H_{16} and octanesulfinic acid with KOH at 200° , but no octane or EtSO_2H . Diethyl sulfone, m. 76° , obtained

from the sulfide, b_p 180°, and HNO_3 (d. 1.49), is not affected by being refluxed with 90% KOH.

ALBERT L. HENNE

Action of the Grignard reagent on highly branched carbonyl compounds. J. B. CONANT AND A. H. BLATT. Harvard Univ. *J. Am. Chem. Soc.* 51, 1227-36(1929).—Besides the normal addn. of the Grignard reagent to CO compds., 3 other reactions—reduction, enolization and condensation—may take place; as the alkyl groups present in the CO compd. are increased in size and complexity, there is a decrease in the rate of the addn. reaction and the other reactions become predominant. The limiting case is $\text{Me}_3\text{CCO}_2\text{Et}$, which is recovered unchanged after boiling with *tert*-BuMgCl(I) for 10 hrs. I and AcH give 80% of $\text{Me}(\text{tert-Bu})\text{CHOH}$. Me_3CHCHO and Me_2CHMgBr give 78% of $(\text{Me}_3\text{CH})_2\text{CHOH}$, whose *phenylurethane* m. 96-9°. Me_3CHCHO and I give 20% of iso-BuOH and 44% of $(\text{Me}_3\text{CH})(\text{Me}_2\text{CHCH}_2)\text{CHOH}$. Et_2CO and BuMgBr give 60% of diethylbutylcarbinol, b_p 116-8°, d_4^{20} 0.8409, n_D^{20} 1.4390. No Et_2CHOH could be isolated; its 3,5-dinitrobenzoate, prepd. for comparison, m. 101°. No definite products could be isolated from Et_2CO and I. $\text{Me}_2\text{C}(\text{Ac})$ and BuMgBr give 25% of methylbutyl-*tert*-butylcarbinol, b_p 84-7°, d_4^{20} 0.8487, n_D^{20} 1.4400, and 30% of $\text{Me}_2\text{CCH}(\text{OH})\text{Me}$. With Me_2CHMgBr 50% of the $\text{Me}_2\text{C}(\text{Ac})$ was recovered, as is also true with I. $(\text{Me}_2\text{CH})_2\text{CO}$ and BuMgBr give 40% of diisopropylbutylcarbinol, b_p 115-8°, d_4^{20} 0.8487, n_D^{20} 1.4435, and 13% of reduction product; Me_2CHMgBr gives 78% of $(\text{Me}_2\text{CH})_2\text{CHOH}$; I gives 80% of the same reduction product. $\text{Me}_2\text{CCOCHMe}_2$ and MeMgI give 60% of methylisopropyl-*tert*-butylcarbinol, b_p 56-7°, d_4^{20} 0.8564, n_D^{20} 1.4430; Me_2CHMgBr gives 88% and I, 90% of $(\text{Me}_2\text{CH})(\text{Me}_2\text{C})\text{CHOH}$. $(\text{Me}_2\text{C})_2\text{CO}$ and MeMgI give 78% of di-*tert*-butylcarbinol, b_p 184-91°, m. 39-41°; Me_2CHMgCl gives unchanged ketone and $(\text{Me}_2\text{C})_2\text{CHOH}$; I gives 60% of the same carbinol. $\text{PhCH}_2\text{CO}_2\text{Et}$ and Me_2CHMgBr give 94% of $\text{PhCH}_2\text{COCHPhCO}_2\text{Et}$.

C. J. WEST

Trimethylacetaldehyde and dimethylethylacetaldehyde. J. B. CONANT, C. N. WEBB AND W. C. MENDUM. Harvard Univ. *J. Am. Chem. Soc.* 51, 1246-55(1929).— Me_2CMgCl and HCHO give 42-50% of $\text{Me}_2\text{CCH}_2\text{OH}$, m. 47-9°; a by-product is formaldehyde di-*tert*-butyl acetal, b_p 182-5°; the latter is recovered unchanged by steam distn. from 80% H_2SO_4 but is hydrolyzed by heating with an equal wt. of 95% EtOH contg. 2 cc. concd. HCl. Dehydration of the carbinol by passing over a Cu catalyst at 250-300° gives 60-65% of Me_2CCHO (I), b_p 74-6°. $\text{Me}_2\text{EtUCH}_2\text{OH}$ is obtained in 40-7% yields by the action of the Grignard reagent and HCHO; the by-product formaldehyde di-*tert*-amyl acetal, b_p 220-4°. Dehydrogenation of the carbinol yields 60-65% of Me_2EtCCHO (II), b_p 104-0.5°, d_4^{22} 0.8040, n_D^{22} 1.3975. Both I and II rapidly undergo autooxidation in the air; II gives 82% of $\text{Me}_2\text{EtCCO}_2\text{H}$. Both I and II undergo photochem. decompn. in bright daylight and in light from a Hg lamp; the effective wave lengths appear to be 2950-3200 Å. U. The products of the reaction are CO and the satd. hydrocarbon. The Cannizzaro reaction may be carried out with I if alk. KOH is employed. I (0.12 mol.) and PrMgBr give 0.06 mol. $\text{Me}_2\text{CCH}(\text{OH})\text{Pr}$, Me_2CHMgCl gives 0.04 mol. $\text{Me}_2\text{CCH}(\text{OH})\text{CHMe}_2$ and about 0.01 mol. $\text{Me}_2\text{CCH}_2\text{OH}$. Me_2CMgCl gives only $\text{Me}_2\text{CCH}_2\text{OH}$. II (0.1 mol.) and PrMgBr give 0.015 mol. $\text{Me}_2\text{CCH}_2\text{OH}$ and 0.045 mol. *tert*-amylpropylcarbinol, b_p 177-8°; 3,5-dinitrobenzoate, m. 71.5-2.5°. II (0.9 mol.) and Me_2CHMgBr give 0.030 mol. $\text{Me}_2\text{CCH}_2\text{OH}$ and 0.924 mol. $(\text{Me}_2\text{CCH}_2)(\text{Me}_2\text{CH})\text{CHOH}$. II (0.5 mol.) and Me_2CMgCl give 0.03 mol. $\text{Me}_2\text{CCH}_2\text{OH}$.

C. J. WEST

Study of some constitutions by means of ozone. RENÉ ESCOURROU. *Bull. soc. chim.* 43, 1088-1100(1928).—The hydrolysis of citral yields a methylheptenone, whose colorless ozonide is decompd. by ice water into Me_2CO and $\text{MeCOCH}_2\text{CH}_2\text{CHO}$, with a little $\text{MeCOCH}_2\text{CH}_2\text{CO}_2\text{H}$ and a high mol. polymer as impurities. The heptenone is thus given the formula $\text{Me}_2\text{C}=\text{CHCH}_2\text{COMe}$. The methylheptenone obtained as a by-product in the prepn. of ψ -ionone gives much HCHO on treatment with O_3 , which may be due to the presence of dipentene in the ketone; nevertheless, this ketone has its double bond located in the α -position, because the ozonide of benzylmethylheptenol, b_p 146-7° (obtained from the ketone by means of PhCH_2MgCl), also yields HCHO on treatment with water. The ozonization of the methylheptenone, b_p 60-1°, d_4^{20} 0.8531, n_D^{20} 1.46195, $[\alpha]_D^{20}$ -45.33°, obtained by fractionation of essence of lemon grass is vitiated by the presence of impurities contg. a terminal CH_2 group, but the ozonide of methylisomethylheptenone, b_p 120-2°, d_4^{20} 0.8555, n_D^{20} 1.45947 (prepd. from the above ketone), gives HCHO and Me_2CO , indicating thus that the original ketone was a mixt. of the α - and the β -forms, with the latter predominating. The dimethyl-

decadiene obtained by dehydration of methylbutylheptenol is $\text{Me}_2\text{C}:\text{CHCH}_2\text{CH}_2\text{CMe}:\text{CHPr}$, because its ozonization gives Me_2CO , PrCHO and $\text{MeCOCH}_2\text{CH}_2\text{CHO}$; since some HCHO is also obtained, the original dienic compd. contained some $\text{CH}_2:\text{CMeCH}_2\text{CH}_2\text{CH}_2\text{CMe}:\text{CHPr}$ as impurity. Quant. expts. in aq. AcOH as solvent confirm the results obtained previously with Java geraniol and citronellol. Similarly, limonene, b. $175-6^\circ$, d^{14}_D 0.847, n^{25}_D 1.4717, $[\alpha]^{17}_D$ 116.1, is shown to contain about 80% of the limonenic and 12% of the terpinolenic forms, the remaining 8% being probably α -terpene. Decompn. of the ozonide gives a small quantity of an insol. waxy substance, m. $88-9^\circ$. Analysis of methylisoamylheptenol shows that this product contains 10–11% of the α -form.

ALBERT L. HENNE

• **Catalytic hydrogenation under reduced pressure.** I. RENÉ ESCOURROU. *Bull. soc. chim.* 43, 1101–15 (1928); cf. following abstr.—Under reduced pressure and in the presence of pumice covered with Pt oxide, the methylalkylheptenols are reduced to the corresponding heptanols, but at atm. pressure in the presence of Ni, the corresponding satd. hydrocarbons are obtained. $\text{Me}_2\text{CH}(\text{CH}_2)_2\text{CHMe}_2$, b.₇₄₀ $133-4^\circ$, d^{11}_D 0.7203, n^{10}_D 1.40672; $\text{Me}_2\text{CH}(\text{CH}_2)_3\text{CHMeEt}$, b.₇₁₀ $158-9^\circ$, d^{11}_D 0.7410, n^{11}_D 1.41611; $\text{Me}_2\text{CH}(\text{CH}_2)_2\text{CHMeCHMe}_2$, b.₇₁₂ $173-6^\circ$, d^{11}_D 0.7637, n^{13}_D 1.4270; $\text{Me}_2\text{CH}(\text{CH}_2)_3\text{CHMeBu}$, b.₇₃₃ $193-6^\circ$, d^{10}_D 0.7642, n^{19}_D 1.42821; $\text{Me}_2\text{CH}(\text{CH}_2)_4\text{CHMePr}$, b.₇₄₅ $173-6^\circ$, d^{11}_D 0.7506, n^{11}_D 1.4214; $\text{Me}_2\text{CH}(\text{CH}_2)_3\text{CHMe}(\text{CH}_2)_2\text{CHMe}_2$, b.₇₄₅ $206-8^\circ$, d^{11}_D 0.7756, n^{11}_D 1.43362; $\text{Me}_2\text{CH}(\text{CH}_2)_4\text{CMe}_2\text{OAc}$, b.₇₄ $98-100^\circ$, d^{12}_D 0.861, n^{12}_D 1.42971. Poisoning of the catalyst may be occasioned by selective adsorption of reaction products, particularly in the reduction of nitriles. Reactivation may be effected by extrn. with Et_2O and combustion of the remaining traces in a current of O at 300° . Under reduced pressure, the activity of the catalyst is decreased and the removal of the reduction products is facilitated, thus favoring selective hydrogenation.

ALBERT L. HENNE

Catalytic hydrogenation under reduced pressure. II. Selective reduction in vacuo of citral, geraniol and limonene. Faculty of Sciences of Lyon. *Bull. soc. chim.* 43, 1204–14; cf. preceding abstr.—Reduction of citral with H_2 using Ni as a catalyst at 190° , gave citronellal, which was identified by its semicarbazone. Using an oxide of Pt as a catalyst and reducing geraniol with H_2 at 130° under a pressure of 50 mm. gave citronellol, identified by its allophanate. Reducing the double bond in the side chain of limonene gave carvomenthene but when the reduction was under diminished pressure only about 10% of the limonene was affected. This is explained by the presence either of an isomer or an impurity, which is easily hydrogenated. Limonene seems to contain about 80% limonene, 12% terpinolene and 8% perhaps of α -terpinene formed from the partial isomerization of terpinolene.

R. C. ROBERTS

Preparation of certain octadecanoic acids and their bactericidal action toward B. leprae. XV. W. M. STANLEY, MARIAN S. JAY AND ROGER ADAMS. Univ. of Illinois, *J. Am. Chem. Soc.* 51, 1261 6 (1929), cf. C. A. 22, 3144.—By using the usual procedure the following di-Et dialkylmalonates were prepd.: *methylpentadecyl*, b. $179-83^\circ$, n^{25}_D 1.4453, d^{25}_4 0.9119 (n and d will follow the b. p. for the following compds.); *methyltridecyl*, b. $167-70^\circ$, 1.4418, 0.9181; *ethyltridecyl*, b. $172-7^\circ$, 1.4461, 0.9163; *propyl-dodecyl*, b. $181-3^\circ$, 1.4423, 0.9249; *propyltridecyl*, b. $183-7^\circ$, 1.4475, 0.9048; *propylundecyl*, b. $178-9^\circ$, 1.4422, 0.9186; *butyldodecyl*, b. $175-80^\circ$, 1.4473, 0.9104; *butyldecyl*, b. $181-3^\circ$, 1.4424, 0.9229; *amylundecyl*, b. $180-5^\circ$, 1.4509, 0.9124; *amylnonyl*, b. $185-6^\circ$, 1.4462, 0.9282; *hexyldodecyl*, b. $185-8^\circ$, 1.4476, 0.9118; *hexyloctyl*, b. $175-8^\circ$, 1.4458, 0.9168; *heptylnonyl*, b. $193-7^\circ$, 1.4471, 0.9118; *diheptyl*, b. $178-80^\circ$, 1.4459, 0.9169; *dioctyl*, b. $192-5^\circ$, 1.4471, 0.9135; *isopropyltridecyl*, b. $179-83^\circ$, 1.4491, 0.9144; *isobutyldodecyl*, b. $180-5^\circ$, 1.4481, 0.9115; *isobutyldecyl*, b. $160-2^\circ$, 1.4428, 0.9207; *sec-butyldodecyl*, b. $180-4^\circ$, 1.4501, 0.9163; *sec-butyldecyl*, b. $196-8^\circ$, 1.4454, 0.9523; *sec-amylundecyl*, b. $175-8^\circ$, 1.4509, 0.9155. The following disubstituted AcOH (octadecanoic acids) were prepd.: $\text{Me}(\text{C}_{17}\text{H}_{33})\text{CHCO}_2\text{H}$, b. $179-83^\circ$, m. $34-5^\circ$; *ethyltridecyl*, b. $167-70^\circ$, m. $23-4^\circ$, n^{25}_D 1.4431, d^{25}_4 0.8767; *propyltridecyl*, b. $179-83^\circ$, m. $31-2^\circ$; *butyldodecyl*, b. $180-4^\circ$, m. $23-4^\circ$, n^{25}_D 1.4528, d^{25}_4 0.8747; *amylundecyl*, b. $180-5^\circ$, n^{25}_D 1.4519, d^{25}_4 0.8820; *hexyldodecyl*, b. $182-4^\circ$, n^{25}_D 1.4527, d^{25}_4 0.8741; *heptylnonyl*, b. $180-3^\circ$, n^{25}_D 1.4528, d^{25}_4 0.8747; *dioctyl*, b. $183-5^\circ$, m. $35-3^\circ$; *isopropyltridecyl*, b. $178-82^\circ$, m. $58-9^\circ$; *sec-butyldodecyl*, b. $178-83^\circ$, m. $38-9^\circ$; *sec-amylundecyl*, b. $175-8^\circ$, m. $37-8^\circ$; *hexadecanoic acids* were prepd. as follows: (substituents of AcOH are given) $\text{Me}(\text{C}_{17}\text{H}_{33})\text{CHCO}_2\text{H}$, b. $173-3^\circ$, m. 24° , n^{25}_D 1.4453, d^{25}_4 0.8765 (m. p., n and d will follow b. p. for acids listed below); *ethylundecyl*, b. $178-9^\circ$, 24° , 1.4460, 0.8808; *propyl-*

undecyl, b_p 178-9°, 16.5-7°, 1.4460, 0.8808; *butyldecyl*, b_p 175-6°, 13-4°, 1.4458, 0.8789; *amylnonyl*, b_p 178-9°, 9-10°, 1.4518, 0.8887; *hexyloctyl*, b_p 165-8°, —, 1.4495, 0.8768; *diheptyl*, b_p 187-9°, 26-7°, 1.4497, 0.8771; *iso-butyldecyl*, b_p 187-8°, 17.5-8°, 1.4448, 0.8763; *sec-butyldecyl*, b_p 185-6°, 38-9°, —, —. Bacteriol. tests with these acids indicate that no ring in the mol. is necessary for bactericidal action. The hexadecanoic acids were in practically every instance more bactericidal than the octadecanoic acid homologs. There is a marked difference, in both series, between the acid with the CO_2H at the end of the chain and acids with the CO_2H in any other position. The effect can hardly be attributed to a chem. specificity of the individual acids but must, probably, be due to a combination of phys. properties common to many of these acids. The mechanism of the bactericidal effect may be looked upon as an adsorption or soln. of the acid in the waxy coating of the bacteria, with a consequent smothering or suffocation of the organism. Comparative tests for a few of the acids toward *B. tuberculosis* and *B. leprae* are reported. A table of bactericidal values of a few acids toward 8 different strains of *B. leprae* is also given. C. J. WEST

Products of partial hydrogenation of higher monoethylenic esters. T. O. HILDITCH AND N. L. VIDYARTHI. London Univ. *Proc. Roy. Soc. (London)* A122, 552-63(1929), cf. Armstrong and Hilditch, *C. A.* 14, 884; 19, 1851.—Me oleate was partially hydrogenated in the presence of Ni on kieselguhr at 217-20°. KMnO_4 oxidation of the ester showed Me stearate produced by hydrogenation and free acids. The latter contained caproic, nonoic, capric and caprylic as monobasic acids and suberic, azelaic, sebacic and dodecanedicarboxylic acids. The evidence indicated that the isomeric acids contained mixts. of $\Delta^{8,9}$ - and $\Delta^{10,11}$ -octadecenic acids in *cis*- and *trans*-forms. Me oleate hydrogenated at 114-18° and oxidized gave similar results. Me palmitate hydrogenated at 170-80° and Me erucate at 200° gave corresponding results. With these 3 esters the product of hydrogenation and oxidation is a mixt. of acids with the ethylenic linkage adjacent to the position it occupied in the original compd. These acids together with the original acid are almost certainly present in both *cis*- and *trans*-forms. This is in harmony with earlier work. **Products of partial hydrogenation of some higher polyethylenic esters.** *Ibid* 563-70; cf. Armstrong and Hilditch, *C. A.* 14, 142; 19, 3054; Hilditch and Moore, *C. A.* 17, 1158.—Me linoleate from soybean oil was hydrogenated at 100-5° to approx. the monoethylenic stage and oxidized. The main component was $\Delta^{9,10}$, with some $\Delta^{8,9}$, and probably some $\Delta^{10,11}$, and a notable amount of $\Delta^{12,13}$, with some $\Delta^{11,12}$ -octadecenic acids. About 2 equivs. of H_2 to 1 of $\Delta^{12,13}$ -acid were present. Similar treatment of Me linoleate and oleate from cottonseed oil showed that the latter was not affected in such a mixt. and in general confirmed the above results. Et linolenate from linseed oil similarly showed $\Delta^{9,10}$ and $\Delta^{12,13}$ -acids. A 3rd isomeride is present in an amount to indicate only that a CO_2H acid contg. 14 or more C atoms was present. Differing from the previous 2 expts. the monobasic acids include members lower than hexoic acid. Hydrogenation of Et linoleate to the diethylenic stage and oxidation shows an acid of mol. wt. lower than 82. It is difficult to state definitely that the remaining unsatn. is at the $\Delta^{11,12}$ position. In these more unsatd. acids hydrogenation of different positions proceeds at different rates, greater the further from the CO_2H group. Isomerization occurs to a lesser degree than with monoethylenic esters. FOSTER DEE SMITH

Esters of α,β -dibromopropionic acid. V. DRULOFEU *Anales. soc. quim. Arg.* 16, 49-52(1928); cf. *C. A.* 22, 3881; 23, 596, 1109, 1110.—Me, Pr and iso-Pr α,β -bromopropionates were prepd. by heating the acid with the appropriate alcohol and H_2SO_4 . The *iso*-Pr ester b_p 212-5°. B. C. A.

Synthesis of the diastereoisometric trisubstituted α -glycols. J. PASCAL *Rev. soc. españ. fis. quim.* 26, 210-21(1928).—Polemical against Tiffeneau and Levy (1914, 18, 2507). B. C. A.

Some derivatives of the aliphatic glycols. GEORGE MACDONALD BENNETT AND FREDERICK HEATHCOAT. Univ. of Sheffield. *J. Chem. Soc.* 1929, 208-74.—The following compds. were prepd. as intermediates in the prepn. of chlorosulfoxides. $\text{HOCH}_2\text{CH}_2\text{OMe}$ (57 g.) in 109 g. PhNMe_2 , treated with 98 g. SOCl_2 , gives 28 g. of $\text{C}_6\text{H}_5\text{CH}_2\text{CH}_2\text{OMe}$, b_p 90.5°, d_4^{20} 1.036, d_4^{25} 1.031; soly. in H_2O 8% by wt. at room temp. From expts. (*C. A.* 19, 2186) on the prepn. of $\text{BrCH}_2\text{CH}_2\text{OR}$ could not be repeated. γ -Chloropropyl 3,5-dinitrobenzoate, m. 77°. PrSH , $\text{ClCH}_2\text{CH}_2\text{CH}_2\text{OAc}$ and NaOH in dil. EtOH, heated 1 hr., give 54% of γ -hydroxydipropyl sulfide, b_p 112°, d_4^{25} 0.9794, n_D^{20} 1.44789; phenylurethan, m. 36°; $\text{BuSC}_2\text{H}_4\text{OH}$ yields a phenylurethan, m. 44.5°. $\text{HO}(\text{CH}_2)_4\text{OH}$, b_p 127°, gives a bis- α -naphthylurethan, m. 198°; with S_2Cl_2 this yields *t*-chlorobutyl alc., b_p 86°, whose α -naphthylurethan, m. 66°. *t*-Chlorobutyl

acetate, b_{17} 87°, b_{21} 98°, results in 88% yield from $\text{HO}(\text{CH}_2)_4\text{OH}$ and AcCl , or from the glycol, S_2Cl_2 and then treating with AcCl ; d_4^{20} (vac.) 1.1024, d_4^{20} (vac.) 1.0803, n_D^{20} 1.43811, 1.44369, 1.45130 for α , β and γ . This condenses with EtSH to give 71% of *Et* δ -hydroxybutyl sulfide (after boiling with dil. EtOH-KOH), b_{19} 120°, d_4^{20} (vac.) 0.9794, n_D^{20} 1.48118 (*phenylurethan*, m. 37°). *Ph* δ -hydroxybutyl sulfide, m. 24° (96% yield); *phenylurethan*, m. 68.5°. $\text{HO}(\text{CH}_2)_6\text{OH}$ yields a *bisphenylurethan*, m. 174°, and a *bis- α -naphthylurethan*, m. 147°. S_2Cl_2 gives *ϵ -chloroamyl alc.*, isolated as the α -*naphthylurethan*, m. 72°. *ϵ -Chloroamyl acetate*, b_{18} 103°, d_4^{20} (vac.) 1.0648, n_D^{20} 1.0648. *Me* ϵ -hydroxyamyl sulfide, b_{18} 121°, d_4^{20} (vac.) 0.9846, n_D^{20} 1.488185 (56% yield); *phenylurethan*, m. 43.5°. *Ph* ϵ -hydroxyamyl sulfide, m. 31.5°; *phenylurethan*, m. 59°.

C. J. WEST

Conversion of tetramethyl- γ - and δ -gluconolactones into the corresponding mannonolactones and of the trimethyl- γ - and δ -xylonolactones into the corresponding lyxonolactones. WALTER N. HAWORTH AND CHARLES WM. LONG. Univ. of Birmingham. *J. Chem. Soc.* 1929, 345-50.—The method used to effect the epimerization of the methylated lactones was to dissolve 2 parts by wt. of the lactone in 1 part of $\text{C}_6\text{H}_5\text{N}$ and 14 parts of H_2O and heat in a closed flask on a boiling H_2O bath during 100-20 hrs., clarify with charcoal, dil. with H_2O and remove the H_2O and $\text{C}_6\text{H}_5\text{N}$ by distn. *in vacuo*, which causes hydrolysis of the $\text{C}_6\text{H}_5\text{N}$ salt. In this way 2,3,5,6-tetramethyl- γ -gluconolactone was converted into the corresponding γ -mannonolactone (60% yield); the reverse change was effected in the same manner; 2,3,4,6-tetramethyl- δ -mannonolactone was converted to the extent of 8% into the corresponding δ -gluconolactone, while the reverse change was 90% complete. 2,3,4-Trimethyl- δ -xylonolactone gives 63% of furancarboxylic acid; the residual sirup gave the *phenylhydrazide* of 2,3,4-trimethyl-lyxonic acid, m. 180.1°. The *phenylhydrazide* of the 2,3,4-trimethyl- δ -xylonic acid, m. 137-8.5°. 2,3,5-Trimethyl- γ -xylonolactone gives 60% of the corresponding γ -lyxonolactone; the *phenylhydrazide*, m. 142°.

C. J. WEST

Synthesis of *l*-2,3,4,6-tetramethyl- δ -gluconolactone and of *l*-2,3,4,6-tetramethyl- δ -mannonolactone from *l*-2,3,5-trimethylarabofuranose. WALTER N. HAWORTH AND STANLEY PEAT. Univ. of Birmingham. *J. Chem. Soc.* 1929, 350-7.—2,3,4-Trimethylarabinose (7.6 g.) condenses with KCN and ClCO_2Me , when cooled and shaken, to give a mixt. of a solid product, $\text{C}_{11}\text{H}_{17}\text{O}_5\text{N}$, m. 100-2°, probably the mannononitrile, and a liquid product, probably a mixt. of the glucono- and mannononitriles. The latter is not very stable. 2,3,5-Trimethyl γ -arabinose condenses with ice-cold KCN and ClCO_2Me to give 84% of a liquid mixt. of *l*-3,4,6-trimethyl 2-carbomethoxyglucono- and mannononitriles, which is somewhat unstable and was therefore hydrolyzed to the corresponding acids. In the 1st stage with HCl in Et_2O there was isolated *l*-2-carbomethoxy 3,4,6-trimethylmannonic acid, m. 155°, and a sirup; this was further hydrolyzed with $\text{N.3 Ba}(\text{OH})_2$ and the product sepd. by PhNHNH_2 ; the less sol. *phenylhydrazide*, m. 137-9°, is that of the mannono compd. Hydrolysis gives *l*-3,4,6-trimethyl- δ -mannonolactone, m. 90-7°, $[\alpha]_D^{20}$ -167° (H_2O , c 1.88), changing after 74 hrs. to 112.8° (const.). Reduction with Na-Hg was very slow. Ag_2O and MeI give *l*-2,3,4,6-tetramethyl δ -mannonolactone, low melting, $[\alpha]_D^{20}$ -150° (H_2O), changing to -58.2° after 150 hrs.; the *phenylhydrazide*, m. 183-4°, $[\alpha]_D^{20}$ 22° (CHCl_3 , c 1.37). From the more sol. *phenylhydrazide* of the original hydrolytic product there was obtained a lactone with $[\alpha]_D^{20}$ -90° (H_2O , c 1.6), changing to -27° in 30 hrs; methylation gave *l*-2,3,4,6-tetramethylgluconolactone, whose *phenylhydrazide* m. 115°. These values correspond with the *d*-enantiomorph.

Parachor and chemical constitution. X. Singlet linkages in chemical coordination compounds. SAMUEL SUGDEN. Univ. of London. *J. Chem. Soc.* 1929, 316-30; cf. *C. A.* 22, 2153.—The parachors of a no. of Ti , Be and Al derivs. of β -diketones have been detd. and found to exhibit precisely the negative anomalies predicted by S. Basic Be propionate and AlBr_3 are also found to contain singlet linkages in the mol. and structures for these compds. are suggested. An alternative hypothesis to account for these negative anomalies has been examd. and is shown to be incompatible with the available data for Hg and Th compds. The free β -diketones and certain derivs. are found to possess an open-chain structure and are not coordinated. The following atomic parachors have been detd.: Hg 69, Ti 64, Pb 76, Be 38, Al 39. The following data are reported: *Et* thallacetoneacetate, d_4^{20} 2.365, γ 30.94 at 94.5°, P 332.2. *Di-Me* Ti benzoylacetate, d and γ , 1.795, 1.783, 1.773, 1.763; 32.08, 31.1, 30.52, 29.85 at 133°, 142.5°, 149° and 157°, resp.; mean P 523.7. TiOEt , d and γ , 3.503, 3.475, 3.430; 38.7, 37.3, 36.2 at 16.5°, 28.5° and 44.5°, resp.; mean P 177.3. TiHCO_2d .

and γ , 4.952, 4.927, 4.912; 81.3, 78.8, 75.3 at 109°, 118° and 124°, resp.; mean P 150.3. $\text{TiCl}_3\text{H}_2\text{O}_2$, d and γ , 3.763, 3.729, 3.705, 3.682; 45.4, 45.0, 44.9, 44.5 at 139°, 150°, 173° and 204°, resp.; mean P 183.5. TiNO_2 , d and γ , 4.897, 4.877, 4.862, 4.843; 112.3, 111.7, 110.4, 109.6 at 211°, 223°, 231.5° and 243°, resp.; mean P 177.3. HgPh_2 , d and γ , 1.940, 1.916, 1.897, 1.879; 35.97, 34.63, 33.42, 32.75 at 129°, 144°, 156° and 168.5°, resp.; mean P 448.7. PbEt_2 , d and γ , 1.640, 1.620, 1.600, 1.586; 28.48, 27.40, 26.39, 25.10 at 20°, 32.5°, 45° and 53.5°, resp.; mean P 456.6. $\text{Be acetylacetonate}$, d and γ , 1.010, 1.001, 0.980, 0.974, 0.964; 27.6, 26.6, 25.3, 24.6, 23.8, 22.9, at 119°, 129°, 142°, 151°, 168° and 169°, resp.; mean P 470.4. $\text{Be propionylacetonate}$, d and γ , 1.038, 1.026, 1.015, 1.007; 31.78, 30.60, 29.20, 28.35 at 60°, 71.5°, 84° and 93°, resp.; mean P 539.0. $\text{Basic Be propionate}$, $\text{Be}_2\text{O}(\text{C}_2\text{H}_3\text{O}_2)_4$, d and γ , 1.054, 1.047, 1.034, 1.022, 1.008; 20.30, 19.59, 18.64, 17.61, 16.62 at 144°, 150°, 162°, 173° and 186°, resp.; mean P 985.4. $\text{Al acetylacetonate}$, d and γ , 0.980, 0.979, 0.971, 0.962, 0.949, 0.915; 18.20, 17.81, 17.28, 16.85, 15.72, 13.21 at 214°, 216°, 223°, 232°, 245.5° and 278.5°, resp.; mean P 680.5. $\text{Al propionylacetonate}$, pale yellow, m , 49°; d and γ , 1.080, 1.074, 1.065, 1.049, 1.036; 29.3, 28.4, 27.6, 25.6, 24.4, at 59°, 65°, 75°, 92° and 105°, resp.; mean P 788.0. Al_2Br_3 , d and γ , 2.632, 2.591, 2.569, 2.531, 2.515; 25.5, 21.2, 23.5, 22.5, 21.7 at 102°, 120°, 130°, 147° and 154°, resp.; mean P 457.6. Acetylacetone , d and γ , 0.973, 0.944, 0.917, 0.902; 32.13, 28.50, 25.70, 24.14 at 11°, 39.6°, 66° and 81°, resp.; mean P 245.4. Propionylacetone , d and γ , 0.959, 0.949, 0.937, 0.930; 30.38, 29.24, 28.10, 27.22 at 18.5°, 29.5°, 41° and 50°, resp.; mean P 279. Benzoylacetone , d and γ , 1.062, 1.054, 1.045, 1.036; 39.1, 38.3, 37.1, 35.8 at 60°, 78.5°, 89° and 100°, resp.; mean P 382.4. $\text{B acetylacetone difluoride}$, d and γ , 1.212, 1.197, 1.177, 1.160; 36.18, 34.55, 32.89, 31.29, at 60°, 74°, 92.5° and 109°, resp.; mean P 300.6. $\text{Sn bisacetylacetone dichloride}$, d and γ , 1.450, 1.444, 1.434; 28.40, 27.88, 27.12 at 208°, 213° and 221°, resp.; mean P 617.2. The following formulas for d are given: $\text{Di-Me Ti benzoylacetone}$, $1.975 - 0.00135d$; TiOEt , $3.543 - 0.00211d$; TiHCO_2 , $4.977 - 0.0028(d - 100)$; $\text{TiCl}_3\text{H}_2\text{O}_2$, $3.990 - 0.00170d$; TiNO_2 , $4.923 - 0.00195d$; HgPh_2 , $2.143 - 0.00158d$; PbEt_2 , $1.673 - 0.00163d$; $\text{Be acetylacetonate}$, $1.119 - 0.00092d$; $\text{Be propionyl acetate}$, $1.008 - 0.00064d$; $\text{basic Be propionate}$, $1.209 - 0.00108d$; $\text{Al acetylacetonate}$, $0.994 - 0.00100(d - 200)$; $\text{Al propionylacetone}$, $1.137 - 0.00096d$; AlBr_3 , $2.861 - 0.00225d$; AcCH_2Ac , $0.984 - 0.00101d$; EtCOCH_2Ac , $0.976 - 0.00093d$; BzCH_2Ac , $1.120 - 0.00080d$; $\text{B acetylacetone difluoride}$, $1.215 - 0.00105d$; $\text{Sn bisacetylacetone dichloride}$, $1.400 - 0.00122(d - 200)$. C. J. WEST.

Mechanism of the cleavage of diethyl α,α' -dibromosuccinate by secondary amines. A new synthesis of cyclobutane derivatives. RYKOLD C. FUSON AND TSI-YU KAO, Univ. of Illinois. *J. Am. Chem. Soc.* 51, 1536-9(1929).—*meso* $(\text{CH}_2\text{CHBr})_2$, refluxed with an excess of NaCN or KCN in abs. EtOH , gives 50-80% of *trans*-cyanocyclobutane-1,2-dicarboxylic acid, b , 152-4°, d_{20}^{25} 1.1103, n_D^{20} 1.4510. Hydrolysis by hot concd. $\text{Ba}(\text{OH})_2$ gives 85-95% of the Ba salt of cyclobutane-1,1,2,2-tetracarboxylic acid; with concd. H_2SO_4 this loses CO_2 to yield a mixt. of the *trans* and *cis* cyclobutane-1,2-dicarboxylic acids, which, treated with concd. HCl , gives the pure *trans* acid. This synthesis is interpreted as evidence in favor of the cyclobutane mechanism proposed for the cleavage of di-Et α,α' -dibromosuccinate by sec. amines. C. J. WEST.

Effect of heat on malic acid. FRANK W. MOUSE, Mass. Agr. Expt. Sta. *Bull. Div. Chem. Soc.* 51, 1276-9(1929).—Malic acid is partly transformed to an anhydride when dried between 75° and 95°, the amt. of change being dependent on both temp. and time of exposure. Solns. of partially dehydrated acid, when neutralized by alkali and then boiled for several hrs., are partially and sometimes completely restored to normal strength. When malic acid occurs in fruits the *detn.* of total acid will be nearer the truth when it is made on undried samples. C. J. WEST.

Dihydroxytartaric acid and its use in the detection and determination of sodium. A. P. OKATOV, University Leningrad. *J. Russ. Phys. Chem. Soc.* 60, 661-8 (1928). The acid was prepd. according to Fenton (*J. Chem. Soc.* 67, 48(1895)) from Et. and dihydroxymaleic acid in glacial AcOH . O. increased the yield to above 90% by adding to the AcOH filtrate sufficient water to decomp. the dihydroxymaleic acid. The soly. of the Na salt was detd. by titrating the solns. with KMnO_4 . At 0° there was 1 part by wt. of the salt in 3123 parts of water, at 10° in 1886 parts. At 0° an opalescence is produced in 5 mins. after the addn. of K dihydroxytartrate to 0.025 N NaCl , while 2 N MgCl_2 shows no change. The K salt cannot be preserved for longer than 2 days in aq. soln. The quant. *detns.* were made by filtering off the Na dihydroxytartrate, dissolving it in an excess of 2 N H_2SO_4 , and titrating with KMnO_4 . The precision averaged about 10 parts per thousand. B. SOYENKOFF.

Condensation products of urea and formaldehyde of high molecular weight. H. SCHREIBLER, F. TROSTLER AND E. SCHOLZ. *Z. angew. Chem.* 41, 1305-9(1928).—Urea and freshly distd. neutral HCHO give hydroxymethylcarbamide, (I), m. 110°. I and AcOH give insol. $(\text{NH}_2\text{CON}:\text{CH}_2)_{12}\cdot\text{H}_2\text{O}$, and sol. $(\text{NH}_2\text{CON}:\text{CH}_2)_{12}\cdot\text{AcOH}$. Treating I with AcOH, then Br, gives $(\text{NH}_2\text{CON}:\text{CH}_2)_3\cdot\text{Br}_2$, which is also obtained from the above high mol. compds. by a Br treatment. The AcOH-Br treatment converts dihydroxymethylcarbamide, m. 133°, into $(\text{HOCH}_2\text{NHCON}:\text{CH}_2)_3\cdot\text{Br}_2$ (II). A prolonged action transforms II into $[\text{CO}(\text{N}:\text{CH}_2)_2]_3\cdot\text{Br}_2$ (III). HCHO and urea condensed in the presence of a small amount of NH_4OH give hydroxymethylmethylenecarbamide, $(\text{HOCH}_2\text{NHCON}:\text{CH}_2)_3\cdot\text{H}_2\text{O}$, which is converted into II by the Br treatment. The product obtained from technical HCHO and urea is hydrolyzed by 20% OH gives HCHO and urea.

Ac_2O , sol. in CHCl_3 , and converted into III by Br. Dimethylurea and HCHO give hydroxymethyl derivs., but no condensation products, showing that the methylenecarbamide radicals are represented correctly by $(\text{NH}_2\text{CON}:\text{CH}_2)_n$. A. L. H.

Hypoglucemia-producing substances. I. **Synthesis of certain guanidine derivatives.** TAIZO KUMAGAI, SIN-ITI KAWAI, YOSHIO SHIKINAMI AND TATSUO HOSONO. *Sci. Papers Inst. Phys. Chem. Res. (Tokyo)* 9, 271-5(1928).—The authors had, previous to the publication of a paper by Frank in which he showed synthalin to be decamethylenediguanidine, synthesized hexamethylenediguanidine and had found it to be almost as effective as synthalin. Following the publication of F.'s paper the authors synthesized the octa- and decamethylenediguanidine compds.; they find the octa-deriv. is the most active. Complete details of the methods of synthesis are given.

G. H. W. LUCAS

Degradation of l-arabinose. VENANCIO DEULOFEU AND RAÚL J. SELVA. Facultad de ciencias exactas, F. y N., Buenos Aires. *J. Chem. Soc.* 1929, 225-7.—The action of MeONa on tetraacetylarononitrile in CHCl_3 or of $\text{Ba}(\text{OH})_2$ on arabononitrile gives 40 and 13%, resp., of erythrose (based on the reducing power), though the amt. actually isolated was very small.

C. J. WEST

Arabinosan. HANS VOGEL. *Helv. Chim. Acta* 11, 1210-13(1928).—Since ordinary arabinose shows decreasing values on mutarotation it is probably the α -form. Three anhydrides (1,2; 1,3; 1,4) are possible. By heating for 2 hrs. at 15 mm. at 160°, just above the m. p., a colorless product results, without loss of H_2O . This shows increasing values on mutarotation, and is the β -form. Continuing the treatment eliminates 11% of the material as H_2O , and produces an arabinosan, $\text{C}_5\text{H}_8\text{O}_4$, $[\alpha]_D^{20}$ 60.5°, m. 80-1°. This is sol. in alc. from which it is pptd. by Et_2O as a white powder. It does not exhibit mutarotation, is hygroscopic, and tastes slightly sweet. It is very sol. in H_2O , sol. in MeOH, HOAc, pyridine, Me_2CO , somewhat sol. in abs. EtOH, insol. in CHCl_3 and in Et_2O , reduces hot Fehling soln. and cold KMnO_4 as rapidly as does α -glucosan. Boiling H_2O regenerates arabinose, $[\alpha]_D^{20}$ 102.2°. Heating α -arabinose produces the β -form which, losing H_2O , gives β -arabinosan. The similarities to α -glucosan indicate here an ethylene oxide system at 1,2. This indicates a close proximity of OH groups on C atoms 1 and 2 in the α -form, in glucose this proximity of groups is found in the β -form. V. suggests that α be used henceforth to designate that form of a sugar showing diminishing values during mutarotation, and that β be used for that form giving, by similar treatment, increasing values. The β -arabinosan, heated with ZnCl_2 at 15 mm. and 150° for 1.5 hrs. gave diarabinosan $(\text{C}_5\text{H}_8\text{O}_4)_2$, $[\alpha]_D^{20}$ 18.9°, m. 153-5°, sol. in H_2O , pptd. by abs. EtOH as a pale yellow amorphous powder. It is very hygroscopic. It is insol. in Et_2O and does not reduce boiling Fehling soln. and it reduces KMnO_4 only slowly.

G. ALBERT HILL

The acetylation of carbohydrates with acetic anhydride and alkali thiocyanates. YOJIRO TSUZUKI. Tokyo Univ. *Bull. Chem. Soc. Japan* 4, 21-3(1929).—NaSCN or KSCN are used instead of NaOAc in the acetylation of starch, glucose and galactose with Ac_2O . The yields are unchanged. Less thiocyanate than acetate is required; also, it is superfluous to dehydrate the salt. The thiocyanates afford an excellent dispersion medium.

ALBERT L. HENNE

Preparation of α - and β -methyl glucosides. THOMAS S. PATTERSON AND JOHN ROBERTSON. Univ. of Glasgow. *J. Chem. Soc.* 1929, 300-2.—Pure anhyd. glucose (200 g.) in 400 g. MeOH (dried over CaO) contg. 3% HCl was boiled 4.5 hrs., 5 g. animal charcoal added and the reaction product filtered and cooled, after 0.75 hr. 82 g. α -Me glucoside, m. 163°. After distg. off 200 cc. MeOH an additional 44 g. crystd. (61.5% , recrystn. gives 93 g. pure I, m. 165-6°. From the mother

liquors 10.2 g. β -Me glucoside is obtained (4.8 g. pure compd., m. 110°). The best practical procedure is to boil overnight.

C. J. WEST

Methylene blue reduction by a mixture of fructose and amino acids. HANS VON EULER AND HUGO JOHANSSON. *Svensk Kem. Tids.* 40, 263(1928). (In German.)—Fructose and amino acids combine to form a substance which reduces methylene blue in alk. solns. and, like glucose-amino acids (C. A. 22, 4551), reduces a given amt. in shorter time as the alky. increases.

A. R. ROSE

Condensation of glucose and fructose. Synthesis of an isosucrose. JAMES C. IRVINE, JOHN W. H. OLDHAM AND ANDREW F. SKINNER. Univ. of St. Andrews. *J. Am. Chem. Soc.* 51, 1279-93(1929); cf. C. A. 22, 2552.—Fructose (65 g.) in 2285 cc. hot abs. EtOH, after cooling, is treated with 250 cc. EtOH contg. 26 g. HCl; the reaction reaches a max. value of $[\alpha]_D^{17}$ in about 10 mins., when it was arrested by adding EtOH to which had been added 18 g. Na; the γ -Et fructoside is isolated as a sirup and should be at once acetylated with Ac_2O and AcONa , giving 33-47 g. *tetraacetyl- γ -ethylfructose* (I), whose $[\alpha]_D$ varied from 39.0 to 47.9° (CHCl_3 , c 5) (because of varying mixts. of α - and β -forms), n_D 1.4528 to 1.4542. The tetra-Ac deriv. in AcCl (10% soln.) is satd. with HCl and allowed to stand at room temp. for 18 hrs., the solvent removed at 45° and the residue in C_6H_6 treated with Ag_2O , giving *tetraacetyl- γ fructose* (II), $[\alpha]_D$ 31.5° (CHCl_3 , c 1.808), 38.7° (C_6H_6 , c 5.379), n_D 1.4645. The same deriv. was obtained from inulin, through the tri-Ac deriv., together with some *triacetyl-anhydrofructose*, which will be described later. The relation of II to γ -fructose was established by methylation. *Tetraacetylchloro- γ -fructose* (III) may be obtained by the action of AcCl on I but is more conveniently prepd. from II; it is unstable and cannot be obtained pure. In attempts to synthesize sucrose from these reagents the following reactions were carried out: condensation of II with tetraacetylbromoglucose in the presence of a base (in this no condensation of the glucose and fructose residues took place); condensation of II with tetraacetylglucose (IV) in the presence of a base or of II and IV in the presence of a dehydrating agent. In each case the only crust product isolated was an *isosucrose octaacetate*, m. 131-2°, $[\alpha]_D$ 19.9° (CHCl_3 , c 3.762), 20.0° (Me_2CO , c 4.072); - 2.0° (C_6H_6 , c 3.918). No sucrose octaacetate was detected, although evidence was obtained that acetylated gluco-fructoses other than isosucrose octaacetate and also diglucoses were formed. The mixed products obtained in this condensation gave a sp. rotation identical with that of sucrose and are converted quantitatively into "invert sugar." This result is, however, fortuitous. *Isosucrose* has been isolated as needles, decomp. 104°, $[\alpha]_D$ 50.0° (MeOH , c 2.130), 34.2° (H_2O , c 5.254), both without mutarotation. Heated at 100° with 0.001 N HCl, inversion takes place, the const. value -19.2° being attained in 90 mins. (195 mins. for sucrose). The collective results lead to the conclusion that sucrose is β -glucosido- α (γ) fructose and that the isosucrose is β -glucosido- β (γ) fructose.

C. J. WEST

Crystalline turanose. C. S. HUDSON AND EUGEN PACSU. *Science* 69, No. 1784, 278 (1929).—Turanose, a disaccharide obtained by weak acid by hydrolysis of identical crystals, with difficulty. Crystals which formed in one sirup after years' standing have been used to seed other sirups freshly made and rapid crystal growth followed. Aq. solns. showed rapid mutarotation; at 20° in a soln. 3 mins. after prepn the rotation was $[\alpha]_D^{20}$ 43.5° and became const. within 20 mins. at 75.6°. It m. 157°. It is a β -form of sugar.

G. H. W. LEE

Progress in the utilization of saccharin by-products in 1927. WALTHER HILZOG. *Metallber.* 18, 903, 1015-6, 1126-7, 1183-4, 1248-9(1928).

E. H.

Carbohydrates. VII. Starch acetate. PERCY BRIGL AND RICHARD SCHNEIDER. *Landwirtschaftl. Hochschule Hohenheim. Ber.* 62B, 99-103(1929); cf. C. A. 23, 1625.—This preliminary report of a study which was undertaken on account of certain divergences between earlier results and those of Peiser (C. A. 21, 2881) is published now because Friese and Smith describe a starch acetate, prepd. by a very mild method (C. A. 23, 302), which differs considerably from B. and S.'s product.* To obtain an acetate of unchanged starch it is essential to use a mild acetylation method such as $\text{Ac}_2\text{O}-\text{C}_6\text{H}_5\text{N}$, whereas P. used $\text{Ac}_2\text{O}-\text{H}_2\text{SO}_4$. To be sure, she had first subjected the starch to swelling with H_2O , which greatly facilitates the attack of the acetylating mixt., but she overlooked the fact, established by B. and S., that such a pre-swollen starch is readily converted by $\text{Ac}_2\text{O}-\text{C}_6\text{H}_5\text{N}$ into a triacetate showing no trace of reduction and easily converted back into starch. Some change in the starch must, no doubt, have occurred, as the regenerated product is better sol. in cold H_2O , but the change is not material as the starch still gives the blue color with I and shows normal cleavage by diastase. P. and S.'s method is even milder; they swell the starch by shaking in $\text{C}_6\text{H}_5\text{N}$ and H_2O . I then acetylate it with $\text{Ac}_2\text{O}-\text{C}_6\text{H}_5\text{N}$ without removing

the swelling agent. They say, however, that their triacetate is practically insol. in org. solvents while B. and S.'s material dissolves well in CHCl_3 and AcOH , and a repetition of F. and S.'s work gave a product showing the same solubilities as the B. and S. compd., B. and S. cannot explain the contrary findings of F. and S. In attempts to det. its mol. wt. in boiling CHCl_3 or by Rast's method the triacetate behaved like a typical colloid and not a trace of it dialyzed in AcOH through a parchment paper which readily let through not only glucose acetate but even maltose acetate. Its mol. wt. must therefore be considerably greater than that of a disaccharide. C. A. R.

Electrolytic reduction of the imides of cyclic acids. Preliminary note. KORRI-AZATH N. MENON AND JOHN I. SIMONSEN. Indian Inst. of Sci., Bangalore. *J. Chem. Soc.* 1929, 302-5.—*Caronimide*, m. 120° , from the anhydride and dry NH_3 at 180° , on electrolytic reduction in H_2SO_4 gives 5% of 4,4-dimethyl-2-piperidone, thick oil; Bz deriv., m. 114° . *Cyclobutane-1,2-dicarboximide*, m. 121° , on electrolytic reduction gives 15% of the γ -lactam of 2-aminomethylcyclobutane-1-carboxylic acid, m. $127-8^\circ$; the NO deriv. is liquid. *Cyclopentane-1,2-dicarboximide*, m. 90° , gives 25% of the γ -lactam of 2-aminomethylcyclopentane-1-carboxylic acid, m. 83° ; *p*-nitrobenzoyl deriv., m. 123° . The lactams cannot be hydrolyzed with $\text{Ba}(\text{OH})_2$; the liquid NO derivs. with dil. alkali evolve N and give Na salts of the corresponding HO-acids.

Double salts of aniline hydrohalides with metal halides. GORDON D. BYRKIT AND WM. M. DEHN. Univ. of Washington. *J. Am. Chem. Soc.* 51, 1167-71 (1929).— PhNH_2 (I) exhibits a wide capacity to form compds. in combination with halogen and different metals; 17 types, including hydrated forms, are recognized. No correlation with properties can be made of all these compds. on the basis of modern theories. The octa-I compd. of Hg is easily prepd. and is of special interest. The known compds. are listed with literature references. The following new compds. are reported: 8(I.HCl). HgCl_2 , m. 231.5° ; 3(I.HCl) 2HgCl_2 , m. 167° ; I.HBr 2HgBr_2 , m. 150° ; I.HI.HgI $_2$, yellow, m. 61° ; 2(I.HCl) CoCl_2 , blue, m. 135° ; 2(I.HCl) AuCl_3 , golden, m. 95° ; I.HCl BiCl_3 , softens 210° (decompn.); I.HCl MnCl_2 ; 2(I.HCl) $\text{MnCl}_2 \cdot 2\text{H}_2\text{O}$, m. above 230° ; 3(I.HCl) AlCl_3 ; 3(I.HCl) SnCl_4 ; 3(I.HBr) AsBr_3 ; I.HgBr $_2$, m. 127° ; I.PbCl $_2$. C. J. WEST

Identification of amines. IV. Methanesulfonamides. C. S. MARVEL, M. D. HELFRICK AND J. P. BELSLEY. Univ. of Illinois. *J. Am. Chem. Soc.* 51, 1272-4 (1929); cf. C. A. 21, 99.—*Methanesulfonamides* are suitable derivs. for many amines and are more readily hydrolyzed than most sulfonamides; the following were prepd. by treating a C_6H_5 soln. of 2 mol. proportions of the amine with a C_6H_5 soln. of 1 mol. proportion of MeSO_2Cl and recrystg. from dil. EtOH: PhNH_2 , m. 100.5° ; *o*- $\text{MeC}_6\text{H}_4\text{NH}_2$, m. 103° ; *p*- $\text{MeC}_6\text{H}_4\text{NH}_2$, m. 102.5° ; *o*- $\text{MeOC}_6\text{H}_4\text{NH}_2$, m. 115.5° ; *p*- $\text{MeOC}_6\text{H}_4\text{NH}_2$, m. 116° ; *p*- $\text{EtOC}_6\text{H}_4\text{NH}_2$, m. 125° ; *o*- $\text{ClC}_6\text{H}_4\text{NH}_2$, m. 90.5° ; *p*- $\text{ClC}_6\text{H}_4\text{NH}_2$, m. 148° ; *p*- $\text{BrC}_6\text{H}_4\text{NH}_2$, m. 136° ; 2,5- $\text{Cl}_2\text{C}_6\text{H}_3\text{NH}_2$, m. 174° ; α - $\text{C}_{10}\text{H}_7\text{NH}_2$, m. 125.5° ; β - $\text{C}_{10}\text{H}_7\text{NH}_2$, m. 153.5° ; $\text{PhO}(\text{CH}_2)_2\text{NH}_2$, m. 79.5° ; PhNHMe , m. 76.5° ; PhNHEt , m. 59° ; PhNHPr , m. 76° ; PhNHBu , m. 73° ; PhNHCH_2Ph , m. 122° . The derivs. of *p*- $\text{MeC}_6\text{H}_4\text{NH}_2$, *o*- $\text{MeC}_6\text{H}_4\text{NH}_2$, *l*-methylamine, *sec*- BuNHPh , Et_2NH , Bu_2NH and Pr_2NH were oils. Derivs. of primary amines are sol. in 10% NaOH. Details are given of the sepn. of a mixt. of PhNH_2 , PhNHMe and PhNMe_2 . Some difficulties are encountered when MeSO_2Cl is used as a reagent for the sepn. of unknown amine mixts. C. J. WEST

A new method for the preparation of styrene (with an appendix on the identification of β -phenylethanol). SÉBASTIEN SABETAY. *Bull. soc. chim.* 45, 69-75 (1929).— $\text{PhCH}_2\text{CH}_2\text{OH}$ is nearly quantitatively converted to $\text{PhCH}:\text{CH}_2$ by heating with solid KOH ("from alc."). This reaction seems applicable to all alcs. of the general formula $\text{ArCH}_2\text{CH}_2\text{OH}$. The phys. consts. of styrene are collected as follows: b. 143° , b_{760} $52-3^\circ$, d_{20}^{20} 0.9038, n_D^{20} 1.5440. S. recommends detection of $\text{PhCH}_2\text{CH}_2\text{OH}$ in complex mixts. by selective dehydration with KOH to styrene and identification of the latter as $\text{PhCHBrCH}_2\text{Br}$ (m. 72°). M. A. DAHLEN

The stereochemistry of zinc and cadmium. W. WAHL. III. *Nord Kemist-molet* (Finland) 1928, 172-6.—Both *m*- and *p*- $\text{C}_6\text{H}_4(\text{NH}_2)_2$ give complex salts with ZnBr_2 and CdBr_2 . Thus with *m*- $\text{C}_6\text{H}_4(\text{NH}_2)_2$ diamines of the rosaniline series are obtained, also with *o*- $\text{C}_6\text{H}_4(\text{NH}_2)_2$, although with lower yields. With *p*- $\text{C}_6\text{H}_4(\text{NH}_2)_2$ a very slightly sol. compd. is obtained, which contains only 1 mol. *p*- $\text{C}_6\text{H}_4(\text{NH}_2)_2$ for each atom Zn. Probably the neutral complex is of the type: $[\text{Zn}(\text{p-phen.})\text{Br}_2]$. CuSO_4 gives an analogous *p*- $\text{C}_6\text{H}_4(\text{NH}_2)_2$ complex, very slightly sol. and stable. O. A. N.

Structure of organic molecular compounds. GEORGE MACDONALD BENNETT AND GERVASE H. WILLIAMS. Univ. of She. *J. Chem. Soc.* 1929, 256-68.—From a con-

sideration of the behavior of NO_2 and NH_2 groups, it follows that *o*-nitrobenzylidialkylamines should show intramol. coordination and that any corresponding self-coordination in the *m*- and *p*-isomers would necessarily be inter-mol. The *o*-isomer should, therefore, have a somewhat lower b. p. than the others and differences in soly. might also arise. The 3 isomeric $\text{O}_2\text{NC}_6\text{H}_4\text{CH}_2\text{NMe}_2$ show a marked difference in volatility, the *o*-, *m*- and *p*-isomers b_p 144°, 160° and 158°, resp. The 3 $\text{O}_2\text{NC}_6\text{H}_4\text{CH}_2\text{NMe}_2$ show a similar difference; *o*-nitrobenzylidimethylamine, b_p 144°; *m*-isomer, b_p 158°; *p*-isomer, b_p 160°; the *HCl* salt of the *o*-isomer, m. 215°; the 3 *picrates*, yellow, m. 143°, 217° and 149°, resp. B.-p. detns. by the Smith and Menzies' method are also given for these 6 amines. The soly. of C_{10}H_8 in these 6 amines and of these amines in $\text{HO}(\text{CH}_2)_2\text{OH}$ is given; in each case the *m*- and *p*-isomers have almost identical solubilities and the *o*-isomer differs to a small but definite extent. Me 5-nitroisophthalate and α - $\text{C}_{10}\text{H}_7\text{NH}_2$ give an orange mol. compd., m. 82°. 5,1,3- $\text{O}_2\text{NC}_6\text{H}_3(\text{SO}_2\text{Cl})_2$, m. 97-8°, crystals with 1 mol. C_7H_8 , yellow; with 1 mol. 1,3,5- $\text{C}_6\text{H}_3\text{Me}_3$, lemon-yellow, m. 68-70°, with 1 mol. PhOMe, bright yellow, m. 55-60°, and with 1 mol. C_{10}H_8 , bright yellow, m. 102-3°. $\text{O}:\text{C}_6\text{H}_4:\text{O}$ and $(\text{Me}_2\text{NC}_6\text{H}_4)_2\text{PhCOH}$ in abs. EtOH give a dark green compd., $\text{C}_{20}\text{H}_{16}\text{O}_7 \cdot 2\text{C}_{17}\text{H}_{12}\text{ON}_2$; it also gives with $(\text{Me}_2\text{NC}_6\text{H}_4)_2\text{CHPh}$ the pale purple compd., $\text{C}_{20}\text{H}_{16}\text{O}_7 \cdot 2\text{C}_{17}\text{H}_{12}\text{N}_2$, m. 71°. *sym*- $\text{Cl}_2\text{C}_6\text{H}_3\text{NH}_2$ yields a *picrate*, deep red, m. 80-3°. 2,3-Dimethylquinoxaline, heated with 7 times its wt. of a mixt. of equal vols. of BzH and PhCH_2OH or PhNO_2 at 180° for 0.5 hr., gives 3-styryl-2-methylquinoxaline, pale yellow, m. 137°; concd. H_2SO_4 gives an intense reddish purple color, which fades to an orange-yellow on diln. with H_2O . A table is given showing the comparative colorations of styrylquinoxalines with concd. H_2SO_4 . The unsubstituted compd. gives a deep reddish purple; the nitrostyryl bases give a less deep color, the methoxystyryl bases a deeper color than the parent compd. These 2 groups each have an increased effect when in the *o*- or *p*-position in the Ph group as compared with that exercised in the *m*-position.

C. J. WEST

Hexaaminobenzene. BERNHARD FLÖRSCHHEIM AND ERIC L. HOLMES. Royal Inst. J. Chem. Soc. 1929, 330-7. Reduction of 2,4,6,1,3,5 $(\text{O}_2\text{N})_6(\text{H}_2\text{N})_6\text{C}_6$ with PhNHNH_2 gives hexaaminobenzene, light brown cubic octahedra, m. 247-8° (decompn.) (atm. of H_2 , rate of heating, 5° per min.); in air the decompn. point is higher, owing to oxidation; moderately easily sol. in cold H_2O and in PhNHNH_2 ; the aq. soln. is light yellow, darkening to brown in a few hrs. and depositing a black solid in 24 hrs. *Hexa-1-deris.*, m. 356-7°, decompn. 363°. *Tetra-HCl salt*, pptd. from concd. HCl as needles which darken at 240°; the satd. aq. soln. with NH_3 gives a black amorphous powder. *Tripicrate*, dark green, infusible powder. *Pentaaminobenzene*, dark brown, m. 228° (decompn.), by the reduction of 2,4,6,1,3- $(\text{O}_2\text{N})_5(\text{NH}_2)\text{C}_6\text{H}$ with PhNHNH_2 . 2,4,6-*Trinitro-1-amino-3,5-dianilinobenzene*, light red, m. 264° (decompn.); no definite product was obtained by heating with PhNHNH_2 . The $\text{C}_6\text{H}_4(\text{NH}_2)_2$ and all known polyamino deriva. of C_6H_6 , its homologs and PhOMe are compared as regards their resistance to atm. oxidation.

C. J. WEST

1 of nitro compounds by aromatic ketols. II. Some *o*-, *m*-, and *p*-azoxy

HUGH B. NISBET. J. Chem. Soc. 1928, 3121-4. The reduction method previously described (cf. C. A. 22, 61) has been applied to *o*- and *m*-compds. but the yields were not so high as in the case of *p*-compds. This was due to difficulties encountered during the isolation of the azoxy compds. Using benzoin as reducing agent, the following new deriva. have been prepd. from the corresponding nitro compounds: *p*-azoxybenzylideneacetophenone, its *o*- and *m*-isomerides, m. 211-3°, 141-2° and 122-3°, resp.; 2-*o*-, 2-*m*-, and 2-*p*-azoxystyryl-3-methylchromones, m. 202°, 275.5° and 281°, resp.; *o*-, *m*-, and *p*-azoxybenzylidene-*p*-bromoanilines, m. 209°, 120° and 218°, resp.; *m*-azoxybenzylidene-*p*-toluidine, m. 150°; Et *p*-azoxybenzoate; 2-nitro-3-azoxystyrene, m. 164°. The condensation of 2,3-dimethylchromone with the appropriate $\text{O}_2\text{N}:\text{C}_6\text{H}_3\text{CHO}$ gives 2-*o*-, 2-*m*-, and 2-*p*-nitrostyryl-3-methylchromones, m. 161°, 212° and 236°, resp. The condensation of *m*- $\text{O}_2\text{NC}_6\text{H}_4\text{CHO}$ and *p*- $\text{BrC}_6\text{H}_4\text{NH}_2$ gives *m*-nitrobenzylidene-*p*-bromoaniline, m. 84°. PhNO_2 treated with benzoin, anisoin and furil gave 20-40%, 80% and 90% yields of benzil, anisil and furil, resp.

A. L. HILL

Relation between the absorption spectra and chemical constitution of certain azo dyes. I. The effect of position isomerism on the absorption spectra of methyl derivatives of benzeneazophenol. WALLACE R. BRUCE. U. S. Bur. Standards. J. Am. Chem. Soc. 51, 1204-12 (1929).— $\text{PhN}:\text{C}_6\text{H}_4\text{OH}$ (I) and the 11 possible mono- and di-Me deriva., in which not more than 1 Me substitution occurs in a C_6H_4 ring, have been prepd. and their absorption spectra measured in 2% aq. NaOH in the visible and ultra-violet regions of the spectrum to about 1250 to 1400 Å. The principal absorption bands appear to be composed of 3 component bands which, added together,

produce the observed bands. The equil. between the 2 components of a band is dependent on the nature of the solvent and the position of the substituting group. An *o*-substitution of the Me radical in I results in an increase in the lower frequency component, with a corresponding decrease in the higher frequency component. A *m*- or *o'*-substitution produces a reverse effect, while the equil. is not affected by either a *m'*- or *p'*-substitution. Substitution of a Me radical in the *p'*-position in I causes an increase in the intensity of the absorption bands irrespective of the type of solvent. Substitution of a Me radical in the *o'*-position in I causes a decrease in the intensity of the absorption bands. The data suggest the possibility of a method of structural analysis for the detn. of the position of a substituting group in a complex mol., and a reverse of this in the prediction of the absorption spectra of compds. of known formula and structure.

Color and constitution. IV. Absorption spectra of nitrophenylhydrazones in alcohol and in alcoholic potassium hydroxide. C. J. WEST
HERBERT H. HANCOCK

components in AcOH, m. 196°. *p*-Hydroxybenzaldehyde *p*-nitrophenylhydrazone, m. 262°. Absorption spectra are given for $\text{RC}_6\text{H}_4\text{CH}=\text{NNHC}_6\text{H}_4\text{NO}_2$, where R is NMe_2OH , Cl, OMe, NMe_2 , CH_3 , and OH. The order of the absorption curves of the hydrazones in EtOH-KOH is in agreement with the series as detd. by their effect in inhibiting or enhancing ionization but the order without the addn. of alkali is entirely different and is in accordance with the well known bathochromic effect of the NH_2 and HO groups.

C. J. WEST

The action of polyatomic alcohols and phenols on arsenic compounds. BERTIL ENGLUND. *Svensk Kem Tids.* 40, 278-85 (1928).—As compds. with low soly. in glacial AcOH react with alcs. and phenols having 2 or more OH groups, forming more sol. compds. The As compd., alc. or phenol and AcOH are kept at 25° in sealed glass tubes for 24 hrs. and the increase in dissolved As detd. by KBrO_3 titration. The g. mol. As/mol. $\text{R}(\text{OH})_2$ ratios are given in the protocols for the action of 27 compds. on $(\text{HO})_2\text{OAsCH}_2\text{CO}_2\text{H}$, 20 on As_2O_3 and 7 on $(\text{HO})_2\text{OAsC}_6\text{H}_4(\text{OH})_2$. For the As-AcOH series these ratios are: $\text{C}_2\text{H}_5(\text{OH})_2$ 0.200, $\text{C}_3\text{H}_7(\text{OH})_2$ 0.475, $\text{C}_4\text{H}_9(\text{OH})_2$ 0.800; $\text{C}_2\text{H}_5(\text{OH})_2$ 0.060; $\text{C}(\text{CH}_2\text{OH})_2$ 0.000, $[\text{Me}_2\text{C}(\text{OH})_2]$ 0.400; $[\text{Ph}_2\text{C}(\text{OH})_2]$ 0.050, *o*- $\text{HOCH}_2\text{CH}_2\text{CO}_2\text{H}$ 0.021; 3,4- $(\text{HO})_2\text{C}_6\text{H}_3\text{CO}_2\text{H}$ 0.053; $[\text{PhCH}(\text{OH})_2]$, *dl* 0.480, *meso* 0.360; $[\text{CH}(\text{OH})\text{CO}_2\text{H}]_2$, *d* 0.440, *meso* 0.200, 1,2- $\text{C}_6\text{H}_4(\text{OH})_2$, *cis* 0.430, *trans* 0.090; $\text{C}_6\text{H}_4(\text{OH})_2$, 0.170, *m* 0.015, *p* 0.002; $\text{C}_6\text{H}_3(\text{OH})_3$, 1,2,3 0.235, 1,2,4 0.210, 1,3,5 0.050; 3,4,5- $(\text{HO})_3\text{C}_6\text{H}_2\text{CO}_2\text{H}$ 0.087; $(\text{CH}_2\text{CO}_2\text{H})_2$ 0.000, $(\text{CHCO}_2\text{H})_2$ 0.000; $\text{HOCH}_2\text{CO}_2\text{H}$ 0.043, Ac_2O 0.021; Bz_2O 0.020. There is a marked increase in the soly. of As when two OH groups are on neighboring C atoms. The reaction takes place only when 5- or 6-atom ring systems can form. There is less increased soly. of As effect by OH groups in the 1,3-positions except for the set $\text{C}[\text{CH}_2\text{OH}]_2\text{-As}_2\text{O}_3$ in which the ratio is 10 times more than the effect of $\text{C}[\text{CH}_2\text{OH}]_2$ on the As-AcOH compd. Stereoisomers give different ratios: *d* $[\text{CH}(\text{OH})\text{CO}_2\text{H}]_2$ is 3 times more sol. than the *meso*-configuration with As from As_2O_3 and 1.5 times with As from the resorcinol compd. Substitutions influence the soly. effect. Mass law constn. are consistent for the 2 reaction types: $(\text{HO})_2\text{OAsCH}_2\text{CO}_2\text{H} + \text{R}(\text{OH})_2 \rightleftharpoons (\text{RO})_2\text{OAsCH}_2\text{CO}_2\text{H} + 2\text{H}_2\text{O}$ and $\text{AsO}(\text{OH})_2\text{CH}_2\text{CO}_2\text{H} + 2\text{R}(\text{OH})_2 \rightleftharpoons \text{As}(\text{RO})_2\text{CH}_2\text{CO}_2\text{H} + 3\text{H}_2\text{O}$. When both reactions apply the *k* for the former decreases and the latter increases with the increase in concn. of $\text{R}(\text{OH})_2$. A. R. ROSE

Heterocyclic compounds containing arsenic. IV. Carbamido derivatives of aryl-arsonic acids. RALPH WM. E. STICKINGS. *J. Chem. Soc.* 1928, 3131-4.—Na-*p*-arsanilate reacts with an aq. suspension of CNBr and yields *p*-carbamidophenyl-arsonic acid. Similarly 3,5- $\text{HO}(\text{H}_2\text{N})\text{C}_6\text{H}_3\text{AsO}_3\text{H}_2$ yields 5-carbamido-2-hydroxyphenyl-arsonic acid; 4,3- $\text{HO}(\text{H}_2\text{N})\text{C}_6\text{H}_3\text{AsO}_3\text{H}_2$ yields 1-aminobenzoxazole-4-arsonic acid; 3,4- $(\text{H}_2\text{N})_2\text{C}_6\text{H}_3\text{AsO}_3\text{H}_2$ yields 2-aminobenzimidazole-5-arsonic acid; 4,3,5- $\text{HO}(\text{H}_2\text{N})\text{-(AcNH)C}_6\text{H}_2\text{AsO}_3\text{H}_2$ yields 1-amino-6-acetamidobenzoxazole-4-arsonic acid and 3,4- $\text{H}_2\text{N}(\text{HO}_2\text{C})\text{C}_6\text{H}_3\text{AsO}_3\text{H}_2$ yields 2,4-diketo-1,2,3,4-tetrahydro-1,3-quinazoline-7-arsonic acid. V. Benzimidazolearsonic acids. MONTAGUE A. PHILLIPS. *Ibid* 3134-40.—The following new compds. are described: 2-methylbenzimidazole-5(6)-arsonic acid nitrate; 2,2'-dimethyl-5,5'-arsenobenzimidazole; 5,5'-arsenobenzimidazole; 2-ethylbenzimidazole-5(6)-arsonic acid and its Ca and Mg salts; 2- α -hydroxyethylbenzimidazole-5(6)-arsonic acid and its Mg salt; benzimidazole-4(7)-arsonic acid, m. 277° (decompn.), and its Ca and Mg salts; 4,4'-arsenobenzimidazole; 2-methylbenzimidazole-4(7)-arsonic acid, m. 280°, and its Ca and Mg salts; 2,2'-dimethyl-4,4'-arsenobenzimidazole; 2- α -hydroxyethylbenzimidazole-4(7)-arsonic acid and its Mg salt;

2,3-dihydroxyquinoxaline-6(7)-arsonic acid, m. $> 300^\circ$, and its Na, Na₂, Ca, Ba and Mg salts; 2,3-dihydroxyquinoxaline-5(8)-arsonic acid, m. $> 300^\circ$, and its Ca, Ba and Mg salts.

ALBERT L. HENNE

Action of phthalic anhydride on triaminoresorcinol. MARIO COVELLO. Univ. Naples. *Rend. accad. sci. Napoli* 33, [3], 240-3(1927).—Piutti obtained substituted quinones by oxidation of 2,4,6-triphthalyltriaminophenol with concd. HNO₃. In analogy with these expts. C. attempted to prep. a substituted hydroxyquinone. The HCl salt of 2,4,6,1,3-(H₂N)₃C₆H(OH)₂ (2.64 g.) was slowly heated with phthalic anhydride (4.44 g.) in CO₂. At 150° the mixt. liquefied and HCl and H₂O were eliminated. There resulted quantitatively 2,4,6-triphthalyltriaminoresorcinol (I), m. above 300°, insol. in H₂O and ordinary solvents; *Ac deriv.*, m. above 300°; *Bz deriv.*, m. 276°; 2,4,6-Triaminoresorcinol triphthalic acid (by dissolving 2.72 g. of I in a soln. of 0.84 g. KOH and neutralizing with HCl), m. 235°; *Ag salt*. When 5 g. of I were treated with HNO₃ (d. 1.48) for 24 hrs., extn. of the reaction product with EtOH yielded only phthalimide. The residue was resinous and could not be purified. G. Schwach

The diphthalyldiaminoquinones. MARIO COVELLO. Univ. Naples. *Rend. accad. sci. Napoli* 34, [3], 149-51(1928); cf. preceding abstr.—The HCl salts of 2,3-, 2,5- and 2,6-diaminohydroquinone (2.12 g.) were condensed with phthalic anhydride (2.92 g.) There resulted quant.: 2,3-, 2,5- and 2,6-diphthalyldiaminohydroquinone. All 3 comds. decomp. 250-300°. Oxidation of these comds. with HNO₃ (d. 1.4) gave 2,3-diphthalyldiaminoquinone, yellow, m. 320°; 2,5-diphthalyldiaminoquinone, yellow, m. 305°, and 2,6-diphthalyldiaminoquinone, yellow, m. 277°, which latter compd. was first prepd. by Piutti. G. Schwach

Some derivatives of tri-*p*-tolylsilicane. ALFRED R. STEELE AND FREDERICK S. KIPPING. Univ. College. *J. Chem. Soc.* 1929, 357 8.—SiCl₄ and *p*-MeC₆H₄MgBr give, among other products, tri-*p*-tolylsilicyl chloride, m. 115-6°, only slowly decompd. by H₂O; dil. NH₄OH-Me₂CO gives tri-*p*-tolylsilicol, m. 99-100°. Evapg. an EtOH soln. of the silicol contg. a few drops 10% NaOH and heating the residue 0.5 hr. on the H₂O bath, gives tri-*p*-tolylsilicyl oxide, m. 223-4°. C. J. WEST

Condensation of *o*-aminophenol and oxalic acid. Preliminary communication. ARTHUR A. LEVINE AND LESTER WEHRHOFF. State Coll. of Washington. *J. Am. Chem. Soc.* 51, 1243-6(1929).—(CO₂H)₂ (1 mol.) and 2 mols. *o*-H₂NC₆H₄OH, intimately mixed and heated at 180-200° for 0.5 hr., give quantitatively the compd. C₁₂H₁₀O₄N₄, red, m. 271-2°, crystd. from PhNO₂ or PhCH₂OH, repptd. unchanged from concd. H₂SO₄, decompd. by heating with alkali; acidifying an alk. soln. which has been heated gives CO₂ and a tarry substance; heating at 280° splits off 1 CO₂; heating at 320° causes complete decompn., CO₂, H₂O, *o*-H₂NC₆H₄OH and a compd. m. above 300° being formed. The di-Na salt may be recrystd. from 80% EtOH contg. a little NaOH, the K salt was more difficult to purify; both decomp. readily on heating in alc. or H₂O. PhNH₂ gives the compd. C₁₂H₁₂O₄N₄, m. 250°. The Na salt and Me₂SO₄ give the *Me ester*, C₁₁H₁₀O₄N₄, m. 240-7°. Ac₂O gives the *Ac deriv.*, red, m. 180°, which is completely decompd. by heating with PhCH₂OH for a few mins. It is reduced by Zn and NaOH, giving a colorless, unstable product. C. J. WEST

2-Substituted derivatives of *p*-cresol. MAURICE COPISAROW. Univ. of Manchester. *J. Chem. Soc.* 1929, 251-3.—A mixt. of 240 g. 99-100% H₂SO₄ and 2.12 mols. 86-92% HNO₃ at 10-12°, is gradually added to 240 g. (*p*-MeC₆H₄)₂CO₂ in 1200 cc. 99-100% H₂SO₄ at 12-15°; the crude product, boiled with 200 g. Na₂CO₃ in 2 l. H₂O, gives 70% 2-NO₂ deriv. (I) and some 3-NO₂ deriv. of *p*-MeC₆H₄OH. I (153 g.), 300 cc. PhMe, 140 g. Me₂SO₄ and 127 g. Na₂CO₃, heated at 110-2° for 4-5 hrs., give 77% of the *Me ether* (II); using the crude I, a 60% yield of the *Me ether* is obtained. *p*-Me(H₂N)C₆H₄OH was obtained by the direct and simultaneous reduction and hydrolysis of the 2-NO₂ carbonate with Na₂S (79% yield) and less satisfactorily with Fe in acid medium. Reduction of II with Fe and AcOH gives 78-82% of the 2-NH₂ deriv. (isocresidine). *p*-MeC₆H₄OH (108 g.) in 42-4 g. NaOH in 500 cc. H₂O below 10°, treated with COCl₂, gives 78-80% of *p*-MeC₆H₄OCOCl, b₁₀ 108°. C. J. WEST

Pyrolysis of benzaldehyde and of benzyl benzoate. CHARLES D. HURD AND C. W. BENNETT. Northwestern Univ. *J. Am. Chem. Soc.* 51, 1197-201(1929). The decompn. of BzH is very slow at 300° but about 33% of it decomp. largely into BzO-CH₂Ph, in 2 hrs. at 350°. A concurrent reaction of much less importance gives rise to CO and C₆H₆. No evidence could be obtained for PhMe or (PhCH₂)₂O as reaction products and BzOH is formed in negligible amts. By passing BzH through a Pyrex tube at 700° at a rate of 1/8 g. per min., about 66% was decompd. The major reaction was the formation of C₆H₆ by loss of CO. Side reactions gave rise to Ph₂ and 1,4-C₆H₄Ph₂. C₁₀H₈ was definitely absent. At 350° BzOCH₂Ph undergoes a reaction

of disproportionation. After 2 hrs.' heating, the major products are Bz_2O , $PhMe$ and BzH . Smaller quantities of $BzOH$ were also identified. Negative searches were made for stilbene, phenanthrene, C_6H_6 , Ph_2 and $(PhCH_2)_2O$ in the products of reaction.

C. J. WEST

The synthesis of the methyl ketones of *p*-tert-butyltoluene and *p*-cymene by the Friedel and Crafts method. MILLER, ALICE LACOURT. Brussels Univ. *Bull. soc. chim. Belg.* 38, 1-20(1929).—Pure *p*- $MeC_6H_4CMe_3$ (I) b. $192-3^\circ$ (cor.), d_{20}^{20} 0.8614, n 1.48709, 1.49187, 1.50175, 1.51006 for α , D , β and γ at 20° . Brought into contact with $AlCl_3$ at room temp., it yields: isobutane, $PhMe$, unchanged $MeC_6H_4CMe_3$, dibutyltoluene, tributyltoluene and a high-boiling residue. Pure *p*-cymene b. $176.2-7.2^\circ$ (cor.), d_{20}^{20} 0.8583, n_{α}^{20} 1.48676, n_D^{20} 1.49083, n_{β}^{20} 1.50089, n_{γ}^{20} 1.50930. Treated with $AlCl_3$ at room temp. it yields C_6H_6 , $PhMe$, $Me_2C_6H_4$, unchanged cymene, 1,3,5-diisopropyltoluene and a high-boiling residue. A mixt. of $AcCl$ and I is dropped into $AlCl_3$ in CS_2 cooled at -10° : the reaction yields 80% $MeC_6H_4AcCMe_3$, m. -2° , b_{12} $133.2-5.0^\circ$, b_{10} $131-4^\circ$, d_0^0 0.9757, d_{20}^{20} 0.9615, n_{α}^{20} 1.51595, n_D^{20} 1.52071, n_{β}^{20} 1.53279; semicarbazone, m. 189.8° ; oxime, m. $121.8-2.0^\circ$; it forms no cryst. compd. with H_3PO_4 , the $-CMe_3$ group is para to the Me group but the position of the Ac group is not indicated. The chief by-product of the reaction is *p*- MeC_6H_4Ac . A similar treatment involving II and $AlCl_3$ yields 97% of 1,2,4- $MeC_6H_3AcCHMe_2$, b_{12} $124.2-5.2^\circ$, d_0^0 0.9864, d_{20}^{20} 0.9654, n_{α}^{20} 1.51389, n_D^{20} 1.51849, n_{β}^{20} 1.53066, n_{λ}^{20} 1.54134. ALBERT L. HENNE

Synthesis of some chalcones. R. L. SHRINER AND E. C. KLEIDERER. Univ. of Illinois. *J. Am. Chem. Soc.* 51, 1267-70(1929).—Hyssopin (I), isolated from *Herba hyssopi* by Tunmann (*C. A.* 12, 2344) and from *Capsella bursa pastoris* by Oesterle (*C. A.* 16, 4013), was considered by the latter to be 2,4,6-(HO) $_3C_6H_2COCH:CHC_6H_3O_2CH_2-3,4$ (II), since piperonal, acetopiperone and 1,3,5- $C_6H_3(OH)_3$ were obtained on decompn. with 33% KOH . Since, however, acetopiperone predominated in the decompn. products, it would seem that I should be 2,4,6-(HO) $_3C_6H_2CH:CHCOC_6H_3O_2CH_2-3,4$ (III). Synthesis of II and III shows that I is really III. 1,3,5- $C_6H_3(OH)_3$ (15 g.) and 20 g. $AcCl$ in 200 cc. $PhNO_2$ and 200 cc. Et_2O , treated with 30 g. $AlCl_3$ during 0.5 hr., the Et_2O distd and 30 g. $AlCl_3$ again added, give 5 g. 2,4,6-trihydroxyacetophenone, light yellow, m. $213-4^\circ$ (cor.); $FeCl_3$ gives a wine-red color. Heating with piperonal and KOH in 50% $EtOH$ gives 2,4,6-trihydroxyphenyl 3,4-methylenedioxyethyl ketone (II), yellow, decomp. $300-10^\circ$; acetate, light yellow, m. $218-20^\circ$. 2,4,6-(HO) $_3C_6H_2CHO$ and acetopiperone, condensed with KOH , give 2,4,6-trihydroxyethyl 3,4-methylenedioxyphenyl ketone (III), orange, decomp. $265-70^\circ$; tri-*Ac* deriv., light yellow, m. $205-6^\circ$. C. J. WEST

New condensations of ketones with phenols. II. Further cresolphorones. JOSEPH B. NIEDERL AND RICHARD CASTY. New York Univ. and Univ. Graz. *Monatsh.* 51, 86-92(1929); cf. *C. A.* 22, 3629.— Me_2CO (1 mol.) and 1 mol. *o*- MeC_6H_4OH were mixed with concd. H_2SO_4 at 0° and allowed to stand 1 week at room temp., giving 35% of di-*o*-tolylphorone, m. 245° ; this also results by treating 1 mol. phorone and 2 mols. *o*- MeC_6H_4OH with concd. H_2SO_4 in the cold; the *Na* salt crysts. in needles; the *K* salt crysts. in plates; di-*Br* deriv., m. 220° ; di-*Bz* deriv., m. 130° ; di-*Me* ether, m. 154° . Me_2CO and *p*- MeC_6H_4OH with cold concd. H_2SO_4 give di-*p*-tolylphorone ether, m. 137° . C. J. WEST

Norephedrine and norpseudoephedrine. I. S. KANAO. *J. Pharm. Soc. (Japan)* 48, 947-58(1928).—K. succeeded in synthesizing ephedrine (*J. Pharm. Soc.* 47, 102(1927)). Employing the same method, reduction of $PhCH(OH)CH(NO_2)Me$ with Zn dust and dil. H_2SO_4 gave norephedrine (I) and nor- ψ -ephedrine (II). The HCl salts of I and II were sepd. by fractional crystn. in abs. alc. Stereoisomers: Nor-*dl*-ephedrine (III), $C_{11}H_{15}ON$, m. $104-5^\circ$; like other ephedrine forms many salts: Hydrochloride, m. 194° ; sulfate, m. $285-6^\circ$; oxalate, m. 245° ; dioxalate, m. $182-3^\circ$. Nor-*dl*- ψ -ephedrine (IV), $C_{11}H_{15}ON$, m. 71° ; sulfate, m. $290-1^\circ$; oxalate, m. 230° . Nor-*d*-ephedrine (V): the *dl*-base and *d*-tartaric acid in warm alc. gave $C_{11}H_{15}ON \cdot C_4H_6O_6 \cdot EtOH$, m. 160° , $[\alpha]_D^{27}$ 34.69° in water. HCl salt, m. $171-2^\circ$, $[\alpha]_D^{27}$ 33.4° sulfate, m. $285-6^\circ$, $[\alpha]_D^{27}$ 31.5° . Nor-*l*-ephedrine (VI). From the mother liquor of nor-*d*-ephedrine *d*-bitartrate, K. obtained nor-*l*-ephedrine *d*-bitartrate, m. 164° , $[\alpha]_D^{28}$ -34.46° in water; sulfate, m. $285-6^\circ$, $[\alpha]_D^{28}$ -31.39° in water. Nor-*l*- ψ -ephedrine (VII). IV and *d*-tartaric acid in warm water gave nor-*l*- ψ -ephedrine *d*-bitartrate, m. 202° , $[\alpha]_D^{20}$ -13.30° in water. HCl salt, m. $180-1^\circ$, $[\alpha]_D^{20}$ -42.68° in water; sulfate, m. $290-1^\circ$, $[\alpha]_D^{25}$ -39.99° . Nor-*d*- ψ -ephedrine (VIII). Nor-*d*- ψ -ephedrine *l*-bitartrate, m. 202° , $[\alpha]_D^{20}$ 13.36° in water.

HCl salt, m. 180-1°, $[\alpha]_D^{20}$ -42.53° in water. Sulfate, m. 280-1°, $[\alpha]_D^{25}$ 40.10° in water. Other chem. properties of nor- and nor- ψ -ephedrine are also given. F. I. NAKAMURA

Derivatives of *p*-methoxycinnamic acid. P. A. FOOTE. *J. Am. Pharm. Assoc.* 17, 958-62(1928).—*p*-Methoxycinnamic acid was obtained from the volatile oil of *Kaempferia galangal* L. The NH_2 salt, prepd. by passing NH_3 into a soln. of the acid in hot toluene, forms white flakes, sol. in H_2O , EtOH and Me_2CO . Ph ester, m. 76-7°, insol. in H_2O but sol. in org. solvents; ester value 217.5. β -Naphthyl ester, flesh-colored, m. 130-1°, ester value 204.1. Thymyl ester, m. 58-9°. Carvacryl ester, m. 78-9°, ester value 179.3. Eugenyl ester, m. 112-3°, ester value 171.0. Phenacryl ester, m. 136°. The ester values could not be detd. accurately. Monoxime of phenacryl ester, m. 116-7°. Carvacryl cinnamate, m. 65-6°, ester value 201.8. These compds. do not inhibit the growth of *Bacillus typhosus* or *B. staphisaurius*. Intravenous and subcutaneous injections into white rats showed no toxicity. L. E. WARREN

Catalytic hydrogenation of different types of unsaturated compounds. IV. Hydrogenation of conjugated systems: piperic acid. SERGEY V. LEBEDEV AND ANASTASIA O. YAKUBCHIK. Military Med. Acad., Leningrad. *J. Chem. Soc.* 1929, 220-5; cf. C. A. 22, 4460.—The hydrogenation of piperic acid in the presence of Pt black, as well as in the presence of colloidal Pt, proceeds according to type II of L.'s classification. The position of the crit. pt. depends upon the catalyst chosen; in the former method, in EtOH, it is at 75-8% H absorbed, whereas in the latter it is at 68-70% if the K salt is used in H_2O . The hydrogenation curves obtained with either catalyst must be related to the same type, although they differ in shape. C. J. WEST

Chlorination of phthalic anhydride in alkaline solution. ERNEST E. AVILES. Univ. College. *J. Chem. Soc.* 1929, 253-6.—A rapid stream of Cl_2 was passed into an ice-cooled soln. of 16.6 g. of $\text{C}_6\text{H}_4(\text{CO}_2\text{H})_2$ in 200 cc. H_2O contg. 28 g. KOH (3 mols. excess) until no apparent further pptn. of acid K salt occurred (total yield, 50%). This ppt. consists mostly of the 4-Cl deriv., with a little 4,5-di-Cl deriv. and some unchanged acid. The use of 5 mols. excess NaOH gives a much larger proportion of the di-Cl deriv., which could not be removed by the methods of purification recommended by Moore, Marrack and Proud (C. A. 16, 417). The sepn. of the 4-Cl deriv. is best accomplished by esterification with MeOH and HCl. The chlorination is not dependent upon the presence of the excess of alkali but results from the direct action of Cl_2 upon the phthalate in soln. The larger yield of pptd. acid salts obtained when excess of alkali is used is due to the salting out by the alkali formed. This is confirmed by comparative expts. with KOH and NaOH, the KOH reaction giving more of the Cl deriv., since the K H 4-chlorophthalate is only sparingly sol. and therefore salts out before dichlorination takes place. C. J. WEST

Rearrangement of pinocarveol and of sabinol. HARRY SCHMIDT. Zentrallaborat. Akt.-Ges. Lignosol. Ber. 62B, 103-7(1929).—If pinocarveol and sabinol are heated with small quantities of Al alcoholate to 150-70° an exceedingly vigorous reaction suddenly sets in, the mass boils violently and it must be cooled to prevent the temp. from rising too high. The original substance is completely changed, pinocarveol chiefly pinocampnone and sabinol tannacetone. The reaction is more or less violent, depending on the amount of catalyst and the length of heating. There are always formed as by-products resinous substances non-volatile with steam, and the elimination of a small quantity of H_2O cannot be avoided. The tannacetone from sabinol is also in part further isomerized to unsatd. ketones (isothujone and probably carvotanacetone). The ring-unsatd. verbenol and carveol, which also have the HO group adjacent to the double bond, do not behave in the same way. C. A. R.

Indian turpentine from *Pinus longifolia*, Roxb. V. The oxidation of *d*- Δ^1 -carene with Beckmann's chromic acid mixture. CHARLES S. GIBSON AND JOHN L. SIMON. Univ. of London. *J. Chem. Soc.* 1929, 305-11; cf. C. A. 18, 247. Oxidation of Δ^1 -carene with Beckmann's reagent gives *l*-trans-caronic acid and terpenylic acid in relatively large amts. and *d*-homoterpenyl Me ketone, terbic acid, *ca*-caronic acid and $\text{Me}_2\text{C}(\text{CO}_2\text{H})_2$ in small quantities. The original should be consulted for the methods of isolation and identification. H_2SO_4 (50%) in AcOH reacts with the hydrocarbon to give, as the main product, a diterpene, b_p 180-6°, d_{20}^{25} 0.9309, n_D^{20} 1.5168, $[\alpha]_D^{25}$ 5.60°. There also results a small amt. of a mixt. of monocyclic terpenes and a trace of *l*-borneol. The terpene fraction b. 174-6°, d_{20}^{25} 0.8500, n_D^{20} 1.4750, $[\alpha]_D^{25}$ -0.5°. Since neither the diterpene nor the terpene yielded cryst. derivs., these were not identified. C. J. WEST

Camphane-3-carboxylic acid and camphanyl ketones. H. RUPF AND H. HIRSCHMANN. Anstalt org. chem. Basel. *Helv. Chim. Acta* 11, 1180-1200(1928).—The reduc-

tion of Et camphane-2-carboxylate with Na + alc. yields 2-camphanylcarbinol, b_{11} 135°, m. 87–8°, $[\alpha]_D^{20}$ –27.75° in C_6H_6 , whose *p*-nitrobenzoate m. 123°. The same compd. is obtained by the reduction of camphane-2-carboxamide, m. 98°. The reaction between Me_2Zn and the acid chloride, $C_{10}H_{17}COCl$, gives 2-acetylcamphane (I), b_{11} 106°, d_4^{20} 0.96186, $[\alpha]_D^{20}$ –54.25°, whose semicarbazone m. 216°, and oxime m. 69°. I condenses with BzH in the presence of HCl , and gives $C_{10}H_{17}COCH:CHPh$, m. 46°, b_{11} 120–1° in cathodic vacuum, $[\alpha]_D^{20}$ 25.85° in C_6H_6 . The reduction of this gives $C_{10}H_{17}CO(CH_2)_3Ph$, b_{11} 200 1°, m. 36°, $[\alpha]_D^{20}$ –24.04° in C_6H_6 . The reaction between Et_2Zn and the acid chloride yields 2-propionylcamphane, b_{11} 128–9°, d_4^{20} 0.9549, $[\alpha]_D^{20}$ –55.69°, whose semicarbazone m. 186°, oxime m. 97–8°. A Friedel and Crafts reaction yields 2-benzoylcamphane, b_{11} 178 80°, d_4^{20} 1.0391, $[\alpha]_D^{20}$ 12.13°. I and $BzOEt$ in the presence of Et_2O and $NaNH_2$ give 2-benzoylacetylcamphane, m. 61°, while oxidation with $NaOBr$ yields an acid, $C_{10}H_{17}CO_2H$, m. 83 4°, $[\alpha]_D^{20}$ –12.99° in C_6H_6 , whose Me ester b_{11} 102°, d_4^{20} 1.0017, $[\alpha]_D^{20}$ –28.0°; it is isomeric with camphane-2-carboxylic acid, m. 73°, $[\alpha]_D^{20}$ –3.26° in C_6H_6 , whose Me ester b_{11} 104–5°, d_4^{20} 1.002, $[\alpha]_D^{20}$ –14.61°; secondary hydrazide, m. 300°. Both acids give the same toluidine salt, m. 185–5.5°. Mg -bornyl chloride and BzH seem to give phenyl-2-camphanylcarbinol, b_{11} 170–5°. A table gives the optical rotations of the above compds. for different wave lengths. The rotation-dispersions of the acids and their esters are normal or nearly so.

ALBERT L. HENNE

Individuality of humulene. A. CHASTON CHAPMAN. *J. Chem. Soc.* 1929, 359–60; cf. *C. A.* 22, 2377.—Reply to Deussen (*C. A.* 23, 1127).—C. sees no reason for changing his conclusion that humulene is not identical with caryophyllene, though, because of the close relation, it is not impossible that in certain reactions intramol. change occurs, the 1 being transformed into the other.

C. J. WEST

The preparation of diethylaminoethanol esters of diphenyl-2-carboxylic acid and derivatives. FRANK BELL. *J. Chem. Soc.* 1928, 3247 9.— o - PhC_6H_4COCl , b_{11} 163°, has a tendency to change into fluorenone by distn.; it yields diphenyl-2-carboxy-2'-diphenylamide, m. 194°, with 2-aminodiphenyl, it reacts with $Et_2NCH_2CH_2OH$ to give diethylaminoethyl diphenyl-2-carboxylate, b_{11} 183°, whose HCl salt m. 109–10° and exhibits anesthetic properties. In a similar way, p - PhC_6H_4COCl chloride yields diethylaminoethyl diphenyl-4-carboxylate, whose HCl salt m. 183°. $SOCl_2$ and diphenamic acid yield 2'-cyanodiphenyl-2-carboxylic chloride, m. 84°, b_{11} 225°; by distn. it gives 3% of 4-cyanofluorenone, m. 243 4°. Diethylaminoethyl 2'-cyanodiphenyl-2-carboxylate forms a HCl salt, m. 189°. The purpose of the work was to synthesize compds. with anesthetic properties.

ALBERT L. HENNE

The action of methyl *p*-toluenesulfonate on α -naphthylamine. V. M. RODIONOV AND V. E. VVEDENSKII. *Bull. soc. chim.* 45, 121 4 (1929); cf. *C. A.* 20, 1795.— α - $C_{10}H_7NH_2$ (1 mole) + p - $MeC_6H_4SO_3Me$ (1 mole) yields 24% α - $C_{10}H_7NH_2$, 23% α - $C_{10}H_7NHMe$, 42% α - $C_{10}H_7NMe_2$ and 5% (α - $C_{10}H_7NH_2$, α - $C_{10}H_7NH_2$, (0.5 mole) + p - $MeC_6H_4SO_3Me$ (1 mole) yields 97% α - $C_{10}H_7NMe_2$ + a little (α - $C_{10}H_7NH_2$).

M. A. DAHLEN

Symmetry of naphthalene. K. LONSDALE (NÉE YARDLEY). Univ. Leeds. *Proc. Leeds Phil. Lit. Soc., Sci. Sect.* 1, 346 8 (1929). On the assumption that a C atom has 2 different kinds of valencies, a structure for $C_{10}H_8$ can be drawn which would explain the theory of de László (*C. A.* 22, 355) that there should be 2 isomeric β -derivs. but only 1 α -deriv.

WALLACE R. BRODE

Naphthalene series. I. Mechanism of the bisulfite reaction of naphthol derivatives. N. N. VOROBYOV WITH A. G. KASSATKIN. Tech. Mendeleev-Inst. Moskau. *Izv.* 62B, 57–68 (1929).—Bucherer, who first studied the reaction whereby naphthylamines are converted into naphthols with acid sulfites and naphthols into naphthylamines with neutral $(NH_4)_2SO_3$ (+ NH_3) assumed that there is formed an intermediate naphthyl sulfite, $C_{10}H_7OSO_2Na$, but later V. isolated and analyzed some of these intermediate products and found their compn. corresponded to an addn. product of 1 mol. H_2SO_3 or sulfite to 1 mol. naphthol; to the product obtained from 5,1- $C_{10}H_6(NH_2)OH$ he assigned the structure I. The reaction was then applied to the $C_{10}H_6(OH)SO_3H$;

the results obtained with the 1,4-acid seemed to confirm V.'s view while those obtained

with the 1,5- and 1,8-acids apparently agreed with the ester structure for the compds. formed. In all these cases, however, the products were obtained by long boiling of the original acids with NaHSO_3 and it seemed quite possible they might have resulted from a secondary reaction. V. and K., therefore, undertook to make such of these products as could be prepd. in the cold, thereby obviating the possibility of secondary reactions. The di-Na salt of 2,1- $\text{C}_{10}\text{H}_6(\text{OH})\text{SO}_3\text{H}$ was accordingly treated in the cold with SO_2 and gave a product which, after drying, had the compn. II. No indication in favor of B.'s formulation was ever observed. To further confirm the correctness of formula II, the compd.'s behavior on diln. and under the influence of HO and H ions was studied. It decompn. even in H_2O into its components, the decompn. increasing with increasing diln.; the decompn. increases rapidly under the influence of H_2O ions (even with such weak alkalis as NaHCO_3); H ions increase the stability of the II and min. traces of acids prevent the decompn. The curves representing the decompn. under these various conditions are very similar to the corresponding curves for the benzeneazo- β -naphthol compd. (III) (cf. C. A. 18, 3374), a fact which, in connection with a whole series of analogies in the chem. character of the bisulfite compds. of the azonaphthol dyes on the 1 hand and the colorless naphthol derivs. on the other, brings out the prime significance in both cases of a reactive HO group for the formation of bisulfite compds. and confirms the structure assigned to the azo dye compds. Furthermore, various heavy metal salts (Ba , Cu , Zn , Hg) were prepd. from II; in every one the metal content corresponded to structure II. The 2,1- $\text{C}_{10}\text{H}_6(\text{ONa})\text{SO}_3\text{Na}$ was obtained in 20 g. yield from 50 g. β -naphthol essentially by Tobias' method. In the decompn. expts. the liberated SO_2 was detd. iodometrically. II. Action of sodium bisulfite on nitrosonaphthols. N. N. VOROZHTZOV AND S. V. BOGDANOV. Polytechn. Inst. Ivanovo-Vosnessensk and Technolog. Mendeleiev-Inst., Moskau. *Ibid.* 68, 80. Reports in the literature show that the reaction between SO_2 and nitrosophenols, if any occurs, is many-sided and generally leads to reduction of the NO group with simultaneous sulfonation in the nucleus. 1,2- $\text{C}_{10}\text{H}_6(\text{NO})\text{OH}$ has not only the ability to undergo such a transformation but also a tendency to the formation of an unstable bisulfite compd. (I) such as had hitherto not been observed with other nitrosophenols. The object of the present investigation was to establish the structure of I and to det. whether other analogous compds. are capable of existence. Although I has long been known its properties have been very incompletely described and the data in this respect do not always agree. Of the 3 structures which have been suggested for it, $\text{C}_{10}\text{H}_6(\text{NO})\text{OSO}_3\text{Na}$ does not agree with its compn., which, as found in this work, corresponds to $\text{C}_{10}\text{H}_6(\text{OH})\text{N}(\text{OH})\text{SO}_3\text{Na}$ (II) or to III. I greatly resembles in its properties bisulfite compds. of the azo dyes, for which evidence has been advanced that have the structure IV, derived from a quinone hydrazone rather than the true form of the dye. To det. whether 1,2- $\text{C}_{10}\text{H}_6(\text{NO})\text{OH}$ reacts with NaHSO_3 in nitroso or the quinone oxime form it was necessary to fix I of the forms. For purpose was chosen the Me ether, which has the latter form, $\text{O}-\text{C}_{10}\text{H}_6-\text{NOME}$. V with NaHSO_3 under the same conditions as with the naphthol itself, gives an product entirely similar in compn. and properties to I. Again, 1,2,6- $\text{C}_{10}\text{H}_6\text{N}(\text{OH})\text{SO}_3\text{Na}$ with NaHSO_3 and NaOH gives a light green di-Na salt, whose isolation, form and purification offered some difficulties because of its great soly., but the that was isolated and especially its easily prepd. and purified Ba salt confirmed the that it was an addn. product analogous to I. Application of the reaction to that of 2,1- and 4,1- $\text{C}_{10}\text{H}_6(\text{NO})\text{OH}$ resulting from the nitrosation of α -naphthol shows that only the 4,1-compd. reacts (with formation of an unstable compd.), although Schmidt claims that the 2,1-compd. forms with SO_2 an $\text{C}_{10}\text{H}_6(\text{NH}_2)(\text{OH})\text{SO}_3\text{H}$ and the 4,1-compd. remains unchanged. The observation of V. and B. can be made the basis of a new method, simpler than all the other ones, for sepg. the 2 isomers. To isolate the 4,1-deriv. from its NaHSO_3 compd., it suffices, after removing the insol. 2,1- $\text{C}_{10}\text{H}_6(\text{NO})\text{OH}$, to add alkali and decomp. the resulting salt with acids. It has not yet been possible to isolate the bisulfite compd. itself in sufficiently pure form. These results indicate that the tendency to form unstable NaHSO_3 addn. products is not limited to 1,2- $\text{C}_{10}\text{H}_6(\text{NO})\text{OH}$, but only those $\text{C}_{10}\text{H}_6(\text{NOH})-\text{O}$ (viz. the 1,2- and 1,4-compds.) react whose structure corresponds to the azo compds. which all react with NaHSO_3 . The bisulfite compds. of the NO derivs. must therefore have the same structure III as those of the azo derivs. I, from 1,2- $\text{C}_{10}\text{H}_6(\text{NO})\text{OH}$ and 2,1- $\text{C}_{10}\text{H}_6(\text{NO})\text{OH}$, allowed to stand in H_2O below 5° , salted out with NaCl and crystd. from H_2O in solvents; the H_2O solns. are yellowish at room temp. but on heating change to red or reddish; acids produce a reddish color without formation of SO_2 or $\text{C}_{10}\text{H}_6\text{N}-\text{OH}$.

after some hrs. the liquid becomes brown and deposits a brown-black substance sol. in alkalis with brown color. NaHCO_3 turns H_2O solns. of I yellow; from not too dil. solns. NaOH ppts. the green salt of $\text{C}_{10}\text{H}_6(\text{NO})\text{OH}$; moderate heating of the solns. of I with NaHSO_3 and HCl ppts. 1,2,4- $\text{C}_{10}\text{H}_5(\text{NH}_2)(\text{OH})\text{SO}_3\text{H}$.

C. A. R.

• **Naphthalic acid derivatives.** KAROL DZIEWONSKI AND ALEXANDER KOCWA. Univ. Krakow. *Bull. intern. acad. Polonaise* 1928, 405-30.—4-Sulfonaphthalic acid (I) has been obtained from acenaphthene by sulfonation with ClSO_3H and subsequent oxidation of the acenaphthenesulfonic acid with $\text{Na}_2\text{Cr}_2\text{O}_7$ in glacial AcOH . A KOH fusion of I (at 160° , then a few mins. at 240°) yields 4-hydroxynaphthalic anhydride (II), m. $350-1^\circ$, which yields α -naphthol by distn. over Ca(OH)_2 . The KOH fusion of II at high temp. yields 5-hydroxy-1-carboxynaphthalene, m. 235° , sol. in the ordinary org. solvents, and gives a purple-brown ppt. with FeCl_3 ; its Bz deriv. m. 241° . The Na salt of I heated at 250° with PCl_5 yields 4-chloronaphthalic anhydride (III), m. $216-7^\circ$. III has also been obtained from the anhydride of I. Boiling III with concd. aq. NH_4OH yields 4-chloronaphthalimide (IV), m. $301-2^\circ$. I and PBr_3 yield 4-bromonaphthalic anhydride (V), m. 296° . V in AcOH with $\text{PhNHNH}_2 \cdot \text{HCl}$ gives the phenylhydrazone, m. $223-4^\circ$. II and PBr_3 give 4-hydroxybromonaphthalic anhydride, m. $266-7^\circ$, insol. in C_6H_6 , $\text{Me}_2\text{C}_2\text{H}_4$, ligroin or CHCl_3 , sol. in AcOH , EtOH or boiling H_2O , sol. with a red color in pyridine and alkalis. The sulfonation of naphthalic anhydride with fuming H_2SO_4 at $100-5^\circ$ yields 3-sulfonaphthalic acid (VI), m. 198° , whose Na salt crystallizes with 1.5 H_2O , and whose anilide m. 297° . The Na salt of VI and PCl_5 yield 3-chlorosulfonaphthalic anhydride (VII), m. $212-3^\circ$. VII and concd. aq. NH_4OH yield 3-amidosulfonaphthalimide, m. 348° , little sol. in boiling H_2O . VI and an excess of PCl_5 yield 3-chloronaphthalic anhydride, m. $223-4^\circ$, whose imide m. 315° and whose fusion with resorcinol gives 3-chloronaphthalfluorescein, red-brown crystals, m. 170° (decompn.). PBr_3 and 3-hydroxynaphthalic anhydride give 3-hydroxybromonaphthalic anhydride, m. $284-5^\circ$, sol. with red color in alk. solns., whose imide m. 339° , Bz deriv. m. $252-3^\circ$. The sulfonation at high temp. of acenaphthene, followed by oxidation with $\text{Na}_2\text{Cr}_2\text{O}_7$, yields 2-sulfonaphthalic acid (VIII) whose PhNH_2 salt m. 290° . The KOH fusion of VIII at $150-80^\circ$ yields 2-hydroxynaphthalic anhydride (IX), m. $245-6^\circ$. The product obtained by coupling IX with PhN_2Cl m. $238-40^\circ$, with $p\text{-O}_2\text{NC}_6\text{H}_4\text{N}_2\text{Cl}$ m. $336-7^\circ$. The benzylation of IX causes the elimination of one of the CO groups, and 2-benzoyloxy-8-carboxynaphthalene, m. $196-7^\circ$, is thus obtained. The methylation of the anhydride of IX with Et_2SO_4 yields 2-methoxynaphthalic anhydride, m. 255° . The phenylhydrazone of IX m. $238-9^\circ$ and its imide m. $303-4^\circ$. A long KOH fusion of VIII at high temp. yields 2-hydroxy-8-carboxynaphthalene, m. 257° , whose Ac deriv. m. $221-2^\circ$ and whose anilide m. $200-10^\circ$. The Na salt of VIII or its anhydride and PCl_5 yield 2-chloronaphthalic anhydride, m. $246-7^\circ$, whose imide m. $332-3^\circ$. PBr_3 and the anhydride of VIII give 2-bromonaphthalic anhydride, m. $253-4^\circ$, whose imide m. 318° and phenylhydrazone m. $251-2^\circ$.

ALBERT L. HENNE

Structure of dihydroxybenzanthrone, obtained by condensation of alizarin with glycerol and sulfuric acid (Ger. 187,495). J. TURSKI AND J. GRYNWASSER. *Roczniki (Chem.)* 9, 78-82 (1929).—In order to det. the structure of dihydroxybenzanthrone, obtained by condensation of alizarin with glycerol and H_2SO_4 , three possible condensation products: 7,8-dihydroxy-1,9-benzanthrone (C. A. 14, 3221), 5,6-dihydroxy-1,9-benzanthrone (I), m. 185° , and 3,4-dihydroxy-1,9-benzanthrone (II), m. 285° , were prepd. I was prepd. by oxidation of 5,6-dihydroxydihydro-1,9-benzanthrone which was obtained from α -naphthyl 1,2-dihydroxyphenyl ketone, prepd. from catechol and $\alpha\text{-C}_{10}\text{H}_7\text{COCl}$. II was obtained from 2,3- $\text{C}_{10}\text{H}_7(\text{OH})_2$ by (a) Friedel-Crafts' and (b) Scholl's method (C. A. 6, 1000; 7, 790). Comparing the properties of I and II with those of the product obtained in the above patent, it was concluded that the product is identical with I. The following new compds. were prepd. in the course of this study: α -naphthyl 1,2-dihydroxyphenyl ketone, m. 118° (diacetate, m. 135°); 5,6-diacetoxy-1,9-benzanthrone, m. 109° ; 2,3-dihydroxy- α -naphthyl Ph ketone, m. 179° ; 2,3-dibenzoxy-1,9-benzanthrone, m. 235° ; 6,7-dibenzoxy-1,9-benzanthrone, m. 188° ; Bz-2,3-dibenzoxy-1,9-benzanthrone, m. 320° (decompn.); Bz-2,3-dihydroxy-1,9-benzanthrone, m. 192° .

Chemistry of perylene. I. FREDERICK A. MASON. *Ind. Chemist* 5, 111-4 (1929).—A review with bibliography.

A. S. CARTER

Perylene and its derivatives. XIX. ALOIS ZINKE, W. HIRSCH AND E. BROZEK. Univ. Graz. *Monatsh.* 51, 205-20 (1929); cf. *C. A.* 23, 1130.—Reduction of 3,4,9,10-tetranitroperylene with NaHSO_3 , Na_2S or SnCl_2 gives dark violet leaflets, which do not m. 360° , which may be a quinhydrone-like mol. compd. of the tetra- NH_2 deriv. and a diaminoperylenequinondilimine ($\text{C}_{20}\text{H}_{12}\text{N}_4$ or $\text{C}_{20}\text{H}_{10}\text{N}_4$); it is best purified from PhNH_2 . Ac_2O gives the dark reddish brown compd., $\text{C}_{20}\text{H}_{12}\text{N}_4$, which does not m. 360° ; concd. H_2SO_4 gives a reddish brown soln. with green fluorescence; this may be of the form I or II. $(\text{COCl})_2$ gives the compd., $\text{C}_{20}\text{H}_{12}\text{N}_4\text{O}_4$, sol. in concd. H_2SO_4 with a red-violet color; the dye bath is violet and colors cotton yellow. BzCl gives the compd., $\text{C}_{24}\text{H}_{18}\text{N}_4$, brown leaflets or needles; concd. H_2SO_4 gives a reddish brown color. $p\text{-BrC}_6\text{H}_4\text{COCl}$ gives the dark brown compd., $\text{C}_{24}\text{H}_{18}\text{N}_4\text{Br}_2$, giving a golden brown color in concd. H_2SO_4 ; $p\text{-ClC}_6\text{H}_4\text{COCl}$ gives the compd., $\text{C}_{24}\text{H}_{18}\text{N}_4\text{Cl}_2$, brownish yellow. BzH gives the compd., $\text{C}_{24}\text{H}_{18}\text{N}_4$, brown, sol. in concd. H_2SO_4 with a reddish brown color. Heating 3,9-dichloro-4,10-dinitro-, the di- NO_2 or tetra- NO_2 deriv. of perylene with concd. H_2SO_4 at $150\text{--}60^\circ$, 150° or $130\text{--}40^\circ$, resp., for 6 hrs. gives 3,9,4,10-perylene-diquinone, recrystd. from 600 parts PhNO_2 , dark garnet-red needles with metallic luster; the vat is dark red with an intense brownish green fluorescence, which dyes cotton a dark reddish brown to olive, with Cr mordant, a deep brown. BzCl in NaOH in the vat gives tetrabenzoyloxyperylene, golden yellow, m. above 380° ; tetrabromobenzoyl deriv., golden yellow, crystg. with 1 PhNO_2 . The quinone and Br in PhNO_2

give the tetra-Br deriv., $\text{C}_{20}\text{H}_8\text{O}_4\text{Br}_4$, dark brown with metallic luster; concd. H_2SO_4 gives a bluish violet soln. with a similar fluorescence; the vat is wine-red and dyes cotton and rayon reddish brown; Cr-mordanted wool dyes a dark violet brown. Chlorination of the quinone gives a mixt. of di-Cl and tetra-Cl derivs.; BzCl gives the tetra-Bz deriv. of the di-Cl deriv., golden yellow; the concd. H_2SO_4 soln. is carmine red with a brick-red fluorescence. XX. KONRAD FUNKE, FRANZ KIRCHMAYER AND HERBERT WOLF. *Ibid* 221-7.—Reduction of dinitroperylene with PhNHNH_2 , N_2H_4 , H_2O in a bomb or in $\text{C}_6\text{H}_5\text{Me}$, or NaHSO_3 gives the diamino deriv., $\text{C}_{20}\text{H}_{12}\text{N}_2$, brown needles, which do not m. 400° ; concd. H_2SO_4 gives a dark green color. Di-Ac deriv., yellow; dichloroacetyl deriv., yellow; di-Bz deriv., yellow; di- p -chlorobenzoyl deriv., yellow; di- p -bromobenzoyl deriv., yellow; di- α -naphthoyl deriv., yellow; perylenediurethan, yellow; dibenzylidene deriv., light brown; di- α -hydroxybenzylidene deriv., Cu-red; monophthaloyl deriv., deep brown; diphtaloyl deriv., orange-red; monophthaloyl-mono- p -chlorobenzoyl deriv., light brown. XXI. ALFRED PONGRAIZ AND EMERICH PÖCHMÜLLER. *Ibid* 228-33.—Heating 3,9-dibenzoyl-4,10-dichloro- or di-bromoperylene with CuCN in quinoline about 1 hr. gives 3,9-dibenzoyl-4,10-diisocyanoperylene, brick-red leaflets, does not m. 360° , sol. in 300 parts PhNO_2 or 80-100 parts quinoline; the concd. H_2SO_4 soln. is emerald-green. Sapon. with concd. H_2SO_4 gives 3,9-dibenzoyl-4,10-diaminoperylene, dark needles with slight metallic luster, concd. H_2SO_4 gives an emerald-green soln., from which H_2O ppt. blue flakes; BzCl gives the tetra-Bz deriv., reddish yellow needles, sinters 350° but does not melt. Perylene, $p\text{-BrC}_6\text{H}_4\text{COCl}$ and AlCl_3 in CS_2 give the di- p -bromobenzoyl deriv., yellow, m. 260° ; the concd. H_2SO_4 soln. is ultramarine-blue; CuCN gives the compd. $\text{C}_{24}\text{H}_{12}\text{O}_4\text{N}_2$, reddish brown, m. 293° ; the sapon. product could not be crystd. Dipropionylperylene, brown, m. 247° ; the concd. H_2SO_4 soln. is blue-violet with red fluorescence. Dibutylperylene, yellow-brown, m. 253° . Zn distn. of these compds. gave unsatisfactory results.

Difurylethylene. PAUL F. BAUM. Iowa State Coll. *J. Am. Chem. Soc.* 51, 1270-1 (1929).—The polythiofurfuraldehyde obtained by Lintau (*C. A.* 5, 765) by the action of H_2O on furfural in dil. aq. soln., on distn. at $10\text{--}15\text{ mm.}$ ($90\text{--}135^\circ$) gives 18% of a compd., m. 100° , mol. wt. 162, which is believed to be difurylethylene; re-crystn. from EtOH causes the compd. to darken.

C. J. WEST

Constitution of matrine. IX. H. KONDO AND E. OCHIAI. Tokyo Imperial Univ. *J. Pharm. Soc. (Japan)* 48, 941-7 (1928); cf. *C. A.* 20, 2853.—By dry distn. of K matrine with soda lime K. obtained 2 fractions, one sol. in K_2HPO_4 and the other insol. By fractional distn. under reduced pressure of this insol. part K. and O. obtained the following fractions (I-V): $C_9H_{13}N$ (I), b_p 49-50°, gives the pine splinter reaction (p. s. r.). Oxidation of I with PbO_2 and H_2SO_4 gave a cryst. substance, m. 59-61°, which has the properties of succinic acid derivs. $C_{11}H_{15}N$ (II), b_p 65-95°, gives the p. s. r. Catalytic reduction of II with Pd and H gave $C_{11}H_{17}N$, b_p 75-80°. This shows the p. s. r. $C_{11}H_{17}N$ (III), b_p 115-20°, gives the p. s. r. IV is a dark brown substance and gives the p. s. r. Reduction of IV with Pd and H gave a yellow liquid, $C_{12}H_{17}N$, b_p 135-40°. Oxidation of $C_{11}H_{17}N$ and III with PbO_2 and H_2SO_4 gave acid and neutral substances. V is a dark brown liquid, b_p 180-210°. Recrystn. in alc. gave a white paraffin-like compd., $(CH_2)_n$, m. 60.1°. It is certain that the dry distn. of K matrine with soda lime gave pyrrole derivs. having the compns. $C_9H_{13}N$, $C_{11}H_{15}N$ and $C_{12}H_{17}N$. $C_{11}H_{15}N$ has 1 unsatd. double bond on the side chain while the other 2 compds. have no unsatd. side chain. All have a pyrrole nucleus. X. Distillation of α -matrinidin with zinc dust. H. KONDO, E. OCHIAI AND S. NAKAMURA. *Ibid* 1035-43.—Distns. of α -matrinidin with Zn dust gave the following constituents: I, ethereal base; II, sol. in K_2HPO_4 ; and III, insol. in K_2HPO_4 . II on further fractional distn. gave IV, b_p 73-6°, V, b_p 117-20°, and VI, b_p 178-80°. IV, $C_{10}H_{15}N$, is in harmony with the $C_{10}H_{15}N$ obtained by distn. of matrine with Zn dust. IV shows no Liebermann reaction. V, $C_{12}H_{17}N$, shows a positive Liebermann reaction. Pt salt, decomp. 317°. V is identical with dihydro- α -matrinidin (*J. Pharm. Soc.* No. 537, 907). VI, $C_{11}H_{15}N$, gives a positive Liebermann reaction. Pt salt decomp. 216-7°. Au salt, m. 120°. Picrate, m. 211°. VI is hardly reducible. III by fractional distn. gave VII, b_p 70-140°, and VIII, b_p above 140°. Both show a positive Liebermann reaction. Catalytic reduction of VII gave K_2HPO_4 -sol. and K_2HPO_4 -insol. fractions. The former is $C_{11}H_{15}N$, m. 150-1°, and the latter corresponds to $C_9H_{13}N$. Summary: Dry distn. of α -matrinidin with Zn dust gave dihydro- α -matrinidin, $C_{10}H_{15}N$, $C_{12}H_{17}N$, NH_3 , $C_9H_{13}N$ and other pyrroles. α -Matrinidin has a pyrroline nucleus and changes to pyrrole derivs. on dehydrogenation (*C. A.* 20, 2853). $C_9H_{13}N$ is formed by decomp. of α -matrinidin. Of two N atoms in $C_{11}H_{15}N$, one has no basic properties while the other acquires such a property on reduction. The former N forms a pyrroline nucleus in α -matrinidin and the latter a quinuclidine nucleus-forming N. The quinuclidine nucleus of α -matrinidin like the pyrroline nucleus loses its basic property on dehydrogenation. The quinuclidine nucleus is made up by condensation of 2 pyrrolidine nuclei and is called hypoquinuclidine. XI. H. KONDO, E. OCHIAI AND K. NISHIMURA. *Ibid* 1043-50.—Methylmatrine Me ester (*C. A.* 21, 2135) in 100 cc. abs. alc. and MeI (48 g.) and Mg (8 g.) in 100 cc. abs. alc. gave 11 g. of a tertiary alc., dimethylmethylmatrinol (I), b_p 174-5°, m. 47.5°. Pt salt decomp. 243-5°. Au salt decomp. 164-6°. Picrate, m. 140°. Methiodide, m. 234-5°. I cannot be acetylated. Dehydration of I gave negative results. I and PCl_5 in $AcCl$ at 100° gave $C_{11}H_{15}N_2Cl$ (II), b_p 171.5°; Pt salt, decomp. 242°. Attempts to take away HCl from II and produce a double bond ended in failure. The authors suggest that

the CO_2H group adjacent to the C of matrine is tertiary, $\begin{array}{c} C \\ \diagup \quad \diagdown \\ C \end{array} \rightarrow CCO_2H$. XII. *Ibid*

1051-64.—Kondo and Ochiai (*C. A.* 21, 2135) obtained by Hofmann's rearrangement of methylmatrine Me ester a primary amine, descarbonylmethylmatrinamine (I), b_p 188-9°. I neutralized with HBr and diazotized with $AgNO_2$ gave descarbonylmethylmatrinan, $C_{10}H_{15}N_2$ (II), b_p 141-4°, d_4^{20} 1.02927, n_D^{20} 1.52747, and descarbonylmethylmatrine alc. (III), $C_{10}H_{15}N_2O$, b_p 180.8°. II does not show Liebermann's reaction. It gave AgI corresponding to 2 Me groups. Pt salt, decomp. 264°. Au salt, decomp. 197°. II, red P and HI heated 5 hrs. at 260-70° gave $C_9H_{13}N$ (IV), b_p 74-5°, and $C_{11}H_{15}N_2$ (V), b_p 147-9°. IV shows no Liebermann reaction. Pt salt, decomp. 198-210°. Au salt, m. 115-7°. III shows Liebermann's reaction. Pt salt, decomp. 239-40°. III contains one HO and two Me radicals. Acetylation and benzoylation gave negative results. It is certain that II does not contain a double bond and on catalytic reduction it loses a Me radical attached to N and produces a secondary amine, $C_{10}H_{15}N_2$. The formation of an imido group in III is interesting. The fact that it gave AgI corresponding to two NMe groups indicates that the N of the pyrrolidine nucleus has the $>NMe$ form and the new $>NH$ radical is the result of the opening of the hypoquinuclidine nucleus and on thermal decompn. the char-

acteristic CH_2 group, which changes into CH , unites with the imido group. It is certain that III contains one OH radical.

F. I. NAKAMURA

Reactions between furfural, aniline and malonic acid. THEODOR BOEHM. Univ. Berlin. *Arch. Pharm.* 267, 129-41 (1929).—Summarizing the results of the present study it is shown that on heating a mixt. of furfural, aniline and malonic acid in alc. there is formed, contrary to the belief of Knoevenagel, furfuralmalonic acid in 50% yield (based on the wt. of furfural), provided the components react at room temp. The furfuralmalonic acid thus formed immediately unites with the condensation product of furfural and aniline, furfuraniline, to yield a salt having a pronounced dye-stuff character. The reactions involved are represented by the following equations: 1. $2\text{PhNH}_2 + 2\text{C}_4\text{H}_3\text{O}\cdot\text{CHO} \rightarrow 2\text{H}_2\text{O} + 2\text{PhN}:\text{CH}\cdot\text{C}_4\text{H}_3\text{O}$. 2. $\text{PhN}:\text{CH}\cdot\text{C}_4\text{H}_3\text{O} + \text{CH}_2(\text{CO}_2\text{H})_2 \rightarrow \text{C}_4\text{H}_3\text{O}\cdot\text{CH}:\text{C}(\text{CO}_2\text{H})_2\cdot\text{NHPh}$. 3. $\text{O}\cdot\text{CH}:\text{CH}:\text{CH}:\text{C}(\text{CO}_2\text{H})_2\cdot\text{NHPh} + \text{O}\cdot\text{CH}:\text{CH}:\text{CH}:\text{C}(\text{CO}_2\text{H})_2\cdot\text{NHPh} \rightarrow \text{PhNHCH}:\text{CH}:\text{CH}:\text{C}(\text{CO}_2\text{H})_2\cdot\text{NHPh}$.

$\text{CH}:\text{NPh} + \text{O}\cdot\text{CH}:\text{CH}:\text{CH}:\text{C}(\text{CO}_2\text{H})_2\cdot\text{NHPh} \rightarrow \text{PhNHCH}:\text{CH}:\text{CH}:\text{C}(\text{CO}_2\text{H})_2\cdot\text{NHPh}$ (I). Reaction 3 finds its

analogy in that between furfuraniline and $\text{PhNH}_2\cdot\text{HCl}$. In this connection a fact is worthy of mention which might lead to another interpretation. Namely, the condensation also takes place when aniline is replaced by the furfuraniline base, $\text{PhNHCH}:\text{CH}:\text{CH}:\text{C}(\text{OH})\text{CH}\cdot\text{NPh}$. On mixing the latter with furfural in alc. and adding the calcd. amt. of malonic acid, the above-mentioned malonic acid salt of the base seps. In the course of a few hrs., however, it passes completely into the furfuralmalonic acid salt (I). With furfural alone the furfuraniline base fails to react. The condensation cannot therefore in this case take place in the above formulated manner. It appears not improbable that in such case an immediate condensation is effected very like that between barbituric acid or malonitrile and aldehydes, and as occasionally observed between malonic acid anilide and aldehydes. This assumption should not be too readily ignored, since one can easily imagine that the methylene H atoms of malonic

acid in the system: $\begin{bmatrix} \text{CH}:\text{C}(\text{OH})\text{CH}\cdot\text{NPh} \\ | \\ \text{CH}:\text{CHNHPH} \end{bmatrix}$ $\begin{matrix} \text{HO}_2\text{C} \\ \text{HO}_2\text{C} \end{matrix} \text{CH}_2$ are, through require-

tion of the CO_2H groups by the base, brought into a similar condition of activation peculiar to the methylene H atoms of barbituric acid. Among the compds. prepd. and characterized in the present investigation are: *Furfuranilino furfuralmalonate*, $\text{C}_{17}\text{H}_{12}\text{O}_6\text{N}_2$, 0.5EtOH, when crystd. from EtOH, nearly black needles with violet sheen, m. 106-7° (the corresponding compds. from MeOH, m. 103-10°, from iso-PrOH, m. 99-100°, from AcOH, m. 117-8°); *HCl salt*, $\text{C}_{17}\text{H}_{12}\text{O}_6\text{N}_2\cdot\text{HCl}$, m. 167-9°; *p-toluidino furfuralmalonate*, $\text{C}_{17}\text{H}_{12}\text{O}_6\text{N}_2$, 0.5EtOH, greenish violet needles, m. 128-9° (decompn.); *m-toluidino furfuralmalonate*, violet needles, m. 98-100°; *p-chloroanilino furfuralmalonate*, $\text{C}_{17}\text{H}_{10}\text{O}_6\text{N}_2\cdot\text{Cl}$, nearly black crystals, m. 120-1°; *p-bromoanilino furfuralmalonate*, greenish black brilliant needles, m. 121-2°; *p-phenetidino furfuralmalonate*, $\text{C}_{19}\text{H}_{14}\text{O}_6\text{N}_2$, dark blue prisms, m. 135-6°; *pseudocumidino furfuralmalonate*, $\text{C}_{19}\text{H}_{14}\text{O}_6\text{N}_2$, 0.5EtOH, dark green crystals, m. 97-9° (decompn.); *furfuranilino malonate*, $\text{C}_{17}\text{H}_{12}\text{O}_6\text{N}_2$, 0.5EtOH, wine-red crystals, m. 107-8°; *furfuranilino oxalate*, $\text{C}_{17}\text{H}_{12}\text{O}_6\text{N}_2$, EtOH, carmine red prisms 135-6° (decompn.); *alc. free salt*, dark violet, m. 138-9°; *furfuranilino nitrate*, $\text{C}_{17}\text{H}_{12}\text{O}_6\text{N}_2$, $\text{C}_2\text{H}_5\text{O}_2$, blue-violet needles, m. 63°; *furfuranilino fumarate*, $\text{C}_{17}\text{H}_{12}\text{O}_6\text{N}_2$, 0.5EtOH, violet needles, m. 137-8°; *furfuranilino tartrate*, $\text{C}_{17}\text{H}_{12}\text{O}_6\text{N}_2$, 0.5EtOH, violet needles, m. 159-62° (decompn.); *furfuranilino citrate*, $\text{C}_{17}\text{H}_{12}\text{O}_6\text{N}_2$, 0.5EtOH, dark violet needles, m. 130-1° (decompn.). W. O. E.

Formation of pyrrolines from γ -chloropropyl and cyclopropyl ketimines. JOHN B. CLOKE. Univ. of Chicago and Rensselaer Polytechnic Inst. *J. Am. Chem. Soc.* 51, 1174-87 (1929).—2-Phenylpyrroline (I) results by the action of PhMgBr upon $\text{Cl}(\text{CH}_2)_2\text{CN}$; most of the I is initially obtained in the form of its HCl salt (II) which results from the rearrangement of $\text{Cl}(\text{CH}_2)_2\text{C}(\text{NH})\text{Ph}$ (III). III was obtained impure from the above reaction if the heating was continued for only 2 hrs.; another portion of the reaction mixt. gave the impure HCl salt, m. 85-8°; its most significant property was the rate of reaction with H_2O at 0°, the const. k for a monomol. reaction being 0.363. If the reaction product of PhMgBr and $\text{Cl}(\text{CH}_2)_2\text{CN}$ is not heated, there is isolated the bromomagnesium deriv. of III, which crysts. with a mol. of EtO, decomps. with dil. HCl gives *phenyl γ -chloropropyl ketone*, b. 120-1°, d_4^{20} 1.149, n_D^{20} 1.55433; *semicarbazone*, m. 136-7°; with cold EtOH- NH_3 the ketone gives about 10% of I. Heating the HCl salt of III above its m. p. causes rearrangement into II. I is also formed by the action of heat on phenylcyclopropyl ketimine. Curves are given

which show the effect of temp. and the presence of the HCl salt on the stability of the base. These facts, together with a general study of ketimine stability, have led to the proof that de Booseré's so-called Et cyclopropyl ketimine-HCl, which is described as remarkably stable toward hydrolysis, is in reality a pyrroline deriv. C. J. WEST

Synthesis and structure in the series of tetrahydrodiphenylene oxides. F. EBEL. *Helv. Chim. Acta* 12, 3-16(1929).—PhONa (dry) and 2-chlorocyclohexanone heated in excess of phenol or an inert solvent yield 2-phenoxycyclohexanone (I), m. 64.5°. If the temp. rises above 84°, especially under the catalytic influence of HCl, H₂O is eliminated from I, yielding tetrahydrodiphenylene oxide (II). Other phenol or naphthol salts may be substituted for PhONa; but other halogenated ketones give negative results. I reacts with PhNHNH₂ forming cyclohexanol-2-one osazone (III), yellow needles, m. 152-3°. E. considers I to possess the cyclic acetal structure:

$\text{CH}_2\text{CH}_2\text{CH}_2\text{CH}_2\text{CH}(\text{C}(\text{OPh})\text{O})$. I is unassociated in PhH, whereas the cor-

responding Et and Me ethers are bimol. E. therefore questions the structure of comps. prepd. by Kotz (cf. C. A. 7, 3748). II heated with S yields diphenylene oxide, but similar dehydrogenation of tetrahydrophenylene naphthylene oxide (IV) (the "brasane" of v. Kostanecki (cf. C. A. 2, 2938)) failed. E. believes IV has the angular structure

instead of the linear structure assigned to it by v. K. The following

comps. are described: 6-(3-Nitrotetrahydrodiphenylene oxide, yellow needles from alc., m. 120.5°. O-Anisyl-lactolide of cyclohexanol-2-one, white needles or prisms from petroleum ether, m. 67.5°. 8-Methoxy-3,4,5,6-tetrahydrodiphenylene oxide, m. 39.5°. β-Naphthyl-lactolide of cyclohexanol-2-one, m. 135°. Tetrahydrophenylene naphthylene oxide (IV), m. 145°. 8-Salicyloylvalerolactone peroxide, m. 191°. M. A. DAHLEN

Interaction of benzyldiphenylpyronone with ammonia and amines. I. SHETTLÉ. *Odessa Chem. Pharm. Inst. J. Russ. Phys.-Chem. Soc.* 60, 1521-33 (1928).—Benzyldiphenylpyronone (I), which was prepd. by Wedekind (C. A. 5, 1273) by condensing PhCH₂COCl by means of NEt₃, forms with NH₃ or amines addn. products (II) which may be regarded as salts, the pyronone acting as an acid. These reactions have now been studied by S. under various conditions, and the products obtained have been examd. These derivs. can be obtained either by passing a current of NH₃ or the corresponding amine into I in 10% aq. K₂CO₃, or by mixing a concd. soln. of the base with a concd. soln. of I, or by adding a concd. aqueous soln. of the HCl salt of the base to a soln. of 1 g. I in 15 cc. of 10% K₂CO₃ soln. The NH₃ deriv. was also prepd. by passing a current of dry NH₃ into fused I; this reaction does not work with amines. **Properties.**—All the derivs. are obtained in good yield. On being heated they commence to decomp. below their m. ps. The m. ps. (with decompn.) of the derivs. are as follows: NH₃, 190-1°, MeNH₂, 180.2°, EtNH₂, 180-3°, PrNH₂, 186-90°, PhNH₂, about 120°, NEt₃, 122-3°. By prolonged heating below their m. ps. they finally split off all NH₃ or the corresponding amine and yield the original pyronone. With the exception of the PhNH₂ and EtNH₂ derivs., they do not dissolve in cold C₆H₆, Et₂O, CHCl₃, ligroin, but have a better soly. in cold EtOH and are readily sol. in hot EtOH. The alc. solns. of the NH₃, PhNH₂ and NEt₃ derivs., after being evapd. 3-4 times, split off the base with formation of the original pyronone; the other amino derivs. are more stable and can be recrystd. without decompn. All the derivs. dissolve in warm carbonates or in cold caustic alkalis, NH₃ or the corresponding amine being split off and the alkaline salt of the pyronone being formed

BERNARD NELSON

Thiochromonediols. F. ARNDT AND B. EISTERT. Univ. Breslau. *Ber.* 62B, 36-44(1929).—As was briefly mentioned by A. (C. A. 20, 1397) and described in detail by E. (Diss. Breslau, 1927), when 2,2-dichlorothiochromonol (I, R = H) is boiled with H₂O it gives, along with thionaphthequinone (II), a colorless compd. (III) to

which was assigned the structure of 2,3-dihydroxythiochromone (thiochromonediol) (IV). A short report on this work is now given because the results have a bearing on the detn. of the structure of the 2,3-dihydroxyquinoline described in the following abstr. The work was done chiefly with the 6-Me compds. ($R = \text{Me}$). Krollpfeiffer and Sommermeyer have pointed out that the S content of the III corresponds to that of a 2,3,4-triketothiochroman (V) but the analyses as a whole agree better with IV. Furthermore, V would be expected to be colored and the simultaneous formation of II could be ascribed only to a further secondary decompn. of V with elimination of CO_2 , whereas III is, as a matter of fact, not changed by H_2O and the treatment of I with H_2O always gives II and III in about equal quantities, with liberation of CO_2 in an amount corresponding to the equation $2\text{C}_{10}\text{H}_6\text{O}_2\text{Cl}_2\text{S}$ (I) $+ 3\text{H}_2\text{O} = \text{C}_{10}\text{H}_6\text{O}_2\text{S}$ (III) $+ \text{C}_8\text{H}_6\text{O}_2\text{S}$ (II) $+ \text{CO}_2 + 4\text{HCl}$. This can be explained by assuming that V is in fact formed first but that 2 mols. react with another mol. of H_2O , 1 being oxidized to II and CO_2 and the other reduced to VI, and the VI, being a ketol, tends to enolize into IV or the thiocoumarindiol VII. That III really contains two HO groups is shown by the easy formation with Ac_2O of a diacetate which is readily saponified back to the original III. On slow addn. of CH_3N_3 , III gives chiefly a mono-Me ether which must be an *O*-ether as it regenerates III with boiling concd. HCl , dissolves in concd. HCl (i. e., has the basic properties of the thiochromone system) and forms the intensely yellow alkali salts, difficultly sol. in 2 *N* alkalis, characteristic of thiochromones. There can be no doubt, therefore, that it is a 2-methoxythiochromonol (VIII) and that the Me radical has entered the 2-HO group. The free diol must, therefore, also contain a 2-HO group (formula IV), at least in part. On further methylation with CH_3N_3 , VIII slowly yields a homogeneous di-Me ether (IX) which can be only a 2,3-dimethoxythiochromone; it dissolves in 3 *N* HCl and on boiling loses one Me group, yielding a mono-Me ether (X) different from VIII and which must therefore be a 2-hydroxy-3-methoxythiochromone. X is also obtained from III with alk. Me_2SO_4 , showing that III dissolves in alkali without rupture of the ring; long boiling with alkalis, however, results in degradation, finally to the corresponding thiosalicylic acid. X reacts vigorously with excess of CH_3N_3 , about half regenerating IX and the other half forming an isomer (XI) of IX which likewise gives no HO or ketone reactions but is also almost completely devoid of basic properties. The difference in the behavior toward CH_3N_3 of VIII and X can be readily explained by assuming that VIII is incapable of further tautomerization while X can pass through the hypothetical keto form XII and then enolize to the coumarin form XIII; both XII and XIII can form with CH_3N_3 isomers of IX having no appreciable basic properties, XII an ethylene oxide, XIII a di-Me ether. As XI does not behave like an ethylene oxide, it is believed to be the 3,4-dimethoxythiocoumarin. Attempts to establish a relationship between XI with the simple thiocoumarin on the 1 hand and with 4-hydroxythiocoumarin on the other are described in R.'s dissertation; the results are in harmony with the structure XI but are not conclusive because the products cannot be characterized. XI is also obtained from the III with CH_3N_3 , in the mother liquors from the VIII, and is formed in larger amount when the III is treated from the very first with an excess of CH_3N_3 . As X is distinctly more acid than VIII, the 2- is more acid than the 3-HO group in III and is therefore methylated first by CH_3N_3 , whereas Me_2SO_4 methylates the 3-HO group so that the 2-MeO group is hydrolyzed by acids like a CO_2Me group, the 3-MeO group with difficulty, like a phenol ether. Again, the 3-HO group gives the characteristic color reactions of a phenolic HO group with FeCl_3 (chromonols and thiochromonols brown-violet, III dark green, VIII blue-green to blue-violet). X, on the other hand, gives a much weaker gray-brown color (undoubtedly because of the presence of XIII while IX and X give no color. Attempts to apply the above series of reactions to thiochromonols failed because the 2,2-dichlorochromonols could not be prepared; the most vigorous chlorination gave only the mono-Cl deriva. I ($R = \text{Me}$) gives 2-methylthiochromonol and SO_2Cl_2 , yellow, m. $138-9^\circ$ (decompn.), gives with boiling H_2O . 2,3-Dichlorothiochromonol (I, $R = \text{H}$), faintly yellow, (decompn.), gradually decompn. in solvents above 70° . 6-Methylthiochromone (IV, $R = \text{Me}$), sepa. from AcOH on slow cooling and scratching in stout mother liquors, on rapid cooling in fine felted needles which rearrange into the form of the mother liquors. At high temps. the felted type is the stable form; on the rearrangement into the stout form is slower than in AcOH . No difference in the behavior of the 2 forms toward CH_3N_3 could be noted. The IV sinters about 224° (decompn.) on rapid, at a lower temp. on slow heating, dissolves in NaOH only on heating, with faint yellow color; diacetate, m. 176° , gives no color with FeCl_3 is not attacked by Br in CHCl_3 . Thiochromonediol, sinters 190° , m. 210° (decompn.)

diacetate, m. 174°. 2-Methoxy-6-methylthiochromonol (VIII), colorless needles becoming yellow on standing, m. 157°. 2,3-Dimethoxy-6-methylthiochromone (IX), m. 120°. 2-Hydroxy-3-methoxy-6-methylthiochromone (X), slender needles with 1 H₂O from half-dild. MeOH, m. 106-7° and, anhyd., 125-6°, slowly reabsorbs the H₂O of crystn. from the air in the cold, dissolves easily in Na₂CO₃ and NH₄OH without color, also slowly in concd. HCl. 3,4-Dimethoxy-6-methylthiocoumarin (XI) (?), m. 52-3°, sol. in 2 N NaOH only on long heating with faint yellow color, K₂Fe(CN)₆ pptg. a colorless oil (dimethoxymethylthionaphthene²); it is insol. in half-concd. HCl and with much fuming HCl gives a cryst. magma of what is apparently an exceedingly unstable HCl salt. Isonitrosochromanone, faintly yellow, turns brown on recrystn., m. 155° (decompn.), is prepd. through the K salt (65-70% yield) from chromanone, K and AmONO in AmOH; 6-Me deriv., m. 162° (decompn.). Chromonol, obtained in 50-70% yield from the above K salt and boiling HCl, m. 181°; 6-Me deriv., m. 175°. 2-Chlorochromonol, from the chromonol with SO₂Cl₂ on the H₂O bath or at 120° or with Cl in CHCl₃, m. 208°, sol. in dil. alkalis with yellow color; 6-Me deriv., m. 192°.

C. A. R.

Syntheses with diazomethane. VI. The reaction of ketones and aldehydes with diazomethane. F. ARNDT, B. EISTERT AND W. ENDER. *Ber.* 62B, 44-56(1929); cf. C. A. 22, 2932.—It had already been pointed out that the reaction leading from an aldehyde to an ethylene oxide is also to be expected of ketones provided the C:O group is influenced by substituents analogously to the C=O group in those aldehydes which yield ethylene oxides, i. e., ketones having a pronounced hydrate-forming tendency. This expectation had been verified in expts. with ketomalonic and mesoxalic esters and alloxan, and the study of a 3rd example, isatin, which is the subject of the present report, had been carried out when there appeared a paper by Meerwein and Burneleit (C. A. 23, 97) which forced A., E. and B. to publish at once their own results and their plans for future work. M. shows that even the simplest ketones (Me₂CO) can react with CH₂N₂ in the presence of catalysts (e. g., H₂O and MeOH). As the chief product from Me₂CO he obtained *asym*-dimethylethylene oxide but he also found new ketones, especially MeCOEt, which, as he emphasizes, can be explained only by a migration

of a Me to the CH₂ group in the intermediate product $\text{MeC} \begin{array}{l} \diagup \text{O} \text{---} \\ \diagdown \text{Me} \end{array} \text{---CH}_2\text{---}$, and he considers

it probable that the O₂NC₆H₄CH₂COMe found by Arndt as by-products in the reaction between *o*- and *p*-O₂NC₆H₄CHO likewise result from a further reaction with CH₂N₂ of O₂NC₆H₄COMe partly formed, with migration of the O₂NC₆H₄ group. A. had interpreted this reaction as following the course $\text{RCHO} \rightarrow \text{RC} \begin{array}{l} \diagup \text{O} \text{---} \\ \diagdown \text{CH}_2\text{---} \end{array} \rightarrow \text{RCH}_2\text{---}$

$\text{CHO} \rightarrow \text{RCH}_2\text{COMe}$, as radical migration seemed little probable under the mild conditions of the reaction, but he now found that if pure *o*- and *p*-O₂NC₆H₄COMe (which give only a yellow color with alkalis in alc.) are allowed to stand 12 hrs. with CH₂N₂ in Et₂O, there are obtained on evapn. residues which in alc. with alkalis give the characteristic intense color reactions of O₂NC₆H₄CH₂COMe if H₂O or MeOH had been present. This strongly supports M.'s view, which is also adopted by A. The reaction of piperonal with CH₂N₂ fully supports A.'s contention, however, that it is the nature of the aldehyde itself, not the exptl. conditions, which det. the course of the reaction; catalysts under certain conditions may accelerate the reaction but do not change it qual. From isatin and CH₂N₂, Heller obtained 2,3-dihydroxyquinoline (I) as chief product, together with substances m. 175° (II) and 190-2° (III). It was to be expected that the real C:O group in isatin, i. e., that in position 3, would first form the intermediate product IV which would then in part form the ethylene oxide (V) and in part rearrange through VI into I. Such proved to be the case; H.'s II is in fact V, characterized by its chlorohydrin. I was also obtained along with the

II, but always with considerable quantities of its 3-Me ether (VII), m. 194°, probably identical with H.'s III. From the results obtained with the thiochromonediois (cf. preceding abstr.) it would have seemed that the 2-HO group in I would be methylated first by CH_3N_3 , but VII, although it forms a difficultly sol. Na salt, is sapond. by concd. HCl only with extreme difficulty and gives no color reaction with FeCl_3 , while 3-hydroxyquinoline does give a brown-red color; VII must therefore be the 3-Me ether and in I it is the 2-HO group which is the less reactive and less acid. VII (or its tautomeric form, for which the betaine structure (VIII, $\text{R} = \text{Me}$) is preferred to the quinolone formula) is only quite weakly acid and in the absence of H_2O is hardly, in its presence only slowly, further methylated to the di-Me ether (IX) which, in the liquid form and as a true quinoline deriv., is pronouncedly basic but rearranges spontaneously into the solid, hardly basic isomer X. All these facts are in harmony with Meyer's observations with carbostyryl. The study of the reaction between ketones and CH_3N_3 will be continued, not from the point of view of the influence of catalysts on the kinetics of the reaction but to det. the influence of constitutional factors on the qual. course of the reaction, including the intermediate stages. *p*-Nitrophenylethylene oxide (34) 3.8 g. from 10 g. $\text{O}_2\text{NC}_6\text{H}_4\text{CHO}$ allowed to stand 3-4 hrs. with 1.5 mols. CH_3N_3 in Et_2O with or without an equal vol. of MeOH , m. 84-5°, boils under atm. pressure without deflagration or material decompn., is only locally altered by moistening with concd. H_2SO_4 but with much acid reacts quite violently, blackening and evolving CO_2 ; concd. HCl liquefies it to the chlorohydrin; boiling 60%, H_2SO_4 gives no odor of HCHO ; HCl , BzCl and Ac_2O are added as with ordinary ethylene oxides but none of these addn. products has thus far been obtained in cryst. form. Along with the oxide are formed (with or without MeOH) 2.6 g. *p*-($\text{CH}_3\text{N}_3\text{C}_6\text{H}_4\text{COMe}$), m. 80°, and 0.3 g. (without MeOH) or 0.6 g. (with MeOH) of *p*-nitrophenylacetone, m. 62°. $\text{C}(\text{OH})_2(\text{CO}_2\text{Et})_2$ (15 g.) added to CH_3N_3 in Et_2O reacts at once with vigorous evolution of N and yields 12 g. di-Et ethylene oxide 1,1-dicarboxylate, b_p 127-8°, insol. in cold 2 *N* NaOH , slowly dissolves on heating with yellow color and development of the odor of alc., evolves CO_2 on acidification. With $\text{C}(\text{OAc})_2\text{Et}_2$ instead of $\text{C}(\text{OH})_2(\text{CO}_2\text{Et})_2$, CH_3N_3 reacts vigorously, to be sure, but there is no evolution of N until, after 2 hrs., the Et_2O is distl. off under atm. pressure. Di-Et ethylene chlorohydrin-1,1-dicarboxylate (41) from 5 g. of the oxide in cold alc. with HCl gas, b_p 152-3°, does not react with CH_3N_3 even in the presence of H_2O . With Ac_2O and FeCl_3 the oxide gives H_2O and a compd., b_p 152-6°. The ethylene oxide (X) obtained from alloxan and CH_3N_3 (described by Biltz and Paetzold as a methylene ether (XII), m. 170°), seps unchanged from Ac_2O after boiling 2 mins. but if a little FeCl_3 is added reaction takes place in the cold with appreciable evolution of heat. XI dissolves in very little 2 *N* NaOH with remarkable evolution of heat, the soln., if kept cold, remains clear (evolving CO_2 on acidification, but on boiling deposits an oil sol. in H_2O and insol. in Et_2O (presumably a uracil or hydantoin); on boiling with much dil. alkali the odor of HCHO develops. *Phenyl glycol*, $-\text{CO}_2\text{C}(\text{OAc})(\text{CH}_2\text{OAc})\text{CO}_2-$, from XI with Ac_2O and FeCl_3 , m. 97°. *Hydrin*, $-\text{CO}_2\text{C}(\text{OH})(\text{CH}_2\text{Cl})\text{CO}_2-$, shows the properties given by B. and P. for the compd. they formulated as $-\text{CO}_2\text{C}(\text{OH})\text{C}(\text{OCH}_2\text{Cl})-$; benzoate, from XI or the chlorohydrin with BzCl in $\text{C}_6\text{H}_5\text{N}$, m. 173-4°. From 10 g. isatin and the CH_3N_3 from 18 cc. $\text{MeN}(\text{NO})\text{CO}_2\text{Et}$ allowed to stand with frequent shaking in Et_2O for 3-4 hrs. at -5° are obtained 1.5-1.8 g. V, 1.5-6.2 g. VII and 2-3 g. I. The faster the action and the more H_2O or MeOH is present, the more completely is the isatin trans. formed but also the more is the I further methylated to VII; the above max. yields correspond to a min. of unchanged isatin. V, faintly yellow, m. 175°, gives no color with FeCl_3 , does not react with $\alpha\text{-O}_2\text{NC}_6\text{H}_4\text{NHNH}_2$, does not dissolve in cold 2 *N* Na_2CO_3 and on heating resinifies, dissolves at once in 2 *N* NaOH with evolution of heat and darkening, gradually dissolves in cold 60% H_2SO_4 and develops the odor of HCHO on boiling while H_2O gives a flocculent ppt. which decomps. around 120° and reduces FeCl_3 , possibly it is methylenedioxindole. 3-Chloromethyl-2-hydroxyindoline, from V and concd. HCl , m. 182-3° (decompn.), gives in aq. alc. no AgCl with AgNO_3 until it has stood for some time (more quickly on heating), gives no color with FeCl_3 , resinifies with BzCl in $\text{C}_6\text{H}_5\text{N}$, behaves like V toward alkalis. 3-Hydroxycarbostyryl (I or VIII, $\text{R} = \text{H}$), m. 257-8°, gives in alc. with FeCl_3 a dark blue-green color, dissolves readily and clear in cold 2 *N* NaOH and even Na_2CO_3 , absorbs Br in CHCl_3 without evolution of HBr , forming a red addn. product converted by alc. into a colorless substitution product which gives a FeCl_3 reaction. 3-Benzoyl, from I boiled a short time with 1 mol. BzCl in $\text{C}_6\text{H}_5\text{N}$, m. 286-7°, gives no color with alc. FeCl_3 , slowly sol. in cold, rapidly in hot 2 *N* NaOH , with hydrolysis in both cases. Dibenzoyl, from I boiled 3 mins. in $\text{C}_6\text{H}_5\text{N}$ with an excess of BzCl , m. 45-6°, slowly

sol. in 2 *N* NaOH, acids pptg. BzOH and a substance giving a FeCl₃ reaction (probably the 2-benzoate); concd. HCl hydrolyzes the dibenzoate to the 3-benzoate. 3-Br like I, the substitution product m. 283°. Benzoate, m. 130-1°, stable toward even boiling 2 *N* NaOH, sapond. by concd. HCl to VII. IX, oil forming in HCl a difficultly sol. complex with HgCl₂. *N*-Methyl-3-methoxycarbostryl (X), m. 70-1°, insol. in 2 *N*, sol. in concd. HCl.

*Quinoline derivatives. XI. Synthesis of substituted 2-phenyl-4-ethylquinolines. HANNS JOHN AND MAX E. SCHMIED. *J. prakt. Chem.* 121, 177-92(1929); cf. *C. A.* 22, 2358.—PhNH₂·HCl (10 g.) and 7.5 g. PhCH·CHCOEt, melted together, cooled, treated with 15 drops concd. HCl and 3.75 cc. H₂O and boiled for 16 hrs., give 14% 2-phenyl-4-ethylquinoline, m. 50°; using the appropriate amine the following derivs. were prepd.: 6,8-di-Me, m. 88° (7.5% yield); 8-MeO, m. 76° (13.1% yield); 5 (or 7)-Me, m. 112° (20% yield); 5 (or 7)-HO, m. 219° (13.9% yield); 5 (or 7)-MeO, m. 52°, from the HO deriv. and Me₂SO₄; 5 (or 7)-EtO, m. 118° (35.7% yield); 6-Me, m. 100° (10.8% yield); 6-Et, m. 158°; 6-Cl, m. 65.6° (2.3% yield); 6-HO, m. 149° (3.6% yield); 6-MeO, m. 193°; 6-EtO, m. 122-3°; the HO deriv., iso-BuI and KOH give the 6-iso-Bu ether, m. 96°; 6-iso-Am ether, m. 91°; 6-allyl ether, m. 116°; 6-phenacyl ether, m. 136°. The HCl, H₂SO₄, and HNO₃ salts are dual. described, as well as many double salts. C. J. WEST

β-Sulphydrylic-α-quinoline-γ-carboxylic acid and some quinoline derivatives. C. GRÄNACHER AND C. KOUNINOTIS. *Zurich Univ. Helv. Chim. Acta* 11, 1241-52 (1928).—Partially a correction to *C. A.* 17, 2424. The compd. previously described as oxindole-β-sulphydrylic acid, prepd. by the action of NaOH on β-rhodanal-oxindole, is now shown to be β-sulphydrylic-α-quinoline-γ-carboxylic acid, C₈H₆·C(CO₂H)·C(SH)·CONH (I), m. 165.7° (decompn.), whose thiobenzyl deriv.

m. 230°, thiocarboxymethyl deriv. m. 218-21° (decompn.). I is reduced by the Clemmensen method to 2-keto-1,2,3,4-tetrahydroquinoline-4-carboxylic acid, C₈H₆·CH(CO₂H)·CH₂·CO·NH, m. 218-9°. Similarly β-rhodanal *N*-methylloxindole

gives β-sulphydrylic-*N*-methyl-α-quinoline-γ-carboxylic acid, C₈H₆·C(CO₂H)·C(SH)·CO·NMe, m. 146-50° (decompn.), whose thiocarboxymethyl deriv. m. 210°.

When I is treated with PhNHNH₂ in boiling MeOH, H₂S is eliminated and the pyrazolone deriv. $\begin{array}{c} \text{NPh} \text{---} \text{CO} \text{---} \text{C} \text{---} \text{C}_6\text{H}_5 \\ | \quad \quad \quad | \\ \text{NH} \text{---} \text{C} \text{---} \text{CO} \text{---} \text{NH} \\ 2 \quad \quad \quad 1' \end{array}$ is obtained. The methylation of this compd.

with MeI gives the 2-Me deriv., m. 266°; the 2-Et deriv., m. 256.8°. Further ethylation of these alkyl derivs. gives the corresponding 2-methyl-1' ethyl deriv., m. 212°, and the 2,1'-di-Et deriv., m. 173-4°. The action of PhNH₂ on I yields the 3-anilino deriv., hydrolyzed to 2,3-diketo-1,2,3,4-tetrahydroquinoline-4-carboxylic acid, while NH₂OH gives the anhydride of 3-oximino-2-keto-1,2,3,4-tetrahydroquinoline-4-carboxylic acid. ALBERT L. HENNE

A synthesis of nonhydrogenated isoquinoline derivatives. ERNST SPÄTH AND NIKOLAUS POLGAR. *Univ. Wien. Monatsh.* 51, 190-204(1929).—Homoveratrylamine (I) yields a formyl deriv., b.p. 170°, m. 40-2°, in 98% yield; with P₂O₅ this gives 72% of 6,7-dimethoxy-3,4-dihydroisoquinoline, whose picrate m. 201-3°; dehydrogenation with Pd (heating 1 hr. at 183-5°) gives 80% of 6,7-dimethoxyisoquinoline, m. 89-91°. I gives an acetate, m. 84-5°; with P₂O₅ in PhMe. there results 80% of the 3,4-dihydro

deriv., b, 165-70°, m. 106-7° (picrate, m. 210-2°), of 1-meth-7-dimethoxyisoquinoline, m. 111-2° (picrate, m. 247-9° (81% yield)), by dehyd. with Pd. The propionate of I, m. 60-1°; with P_2O_5 this gives 94% of the dihydro base (picrate, m. 195-6°), of 1-ethyl-6,7-dimethoxyisoquinoline, m. 75-6° (picrate, m. 213-4° (83% yield)). The butyryl deriv. of I, m. 54-5° (quant. yield), gives 93% of the 3,4-dihydro deriv. (picrate, m. 180-1°), of 1-propyl-6,7-dimethoxyisoquinoline, m. 83-4° (picrate, m. 186-7°). Homopiperonylamine yields a formyl deriv., m. 62-3°; Ac deriv., m. 105-6°. 3,4-Dihydro-6,7-methylenedioxyisoquinoline, m. 92-4° (picrate, m. 230-2°); 1-Me deriv., m. 89-91° (picrate, m. 242-4°); 1-Et deriv., m. 96-7° (picrate, m. 205-6°); 1-Pr deriv., m. 78-9° (picrate, m. 183-4°). 6,7-Methylenedioxyisoquinoline, m. 127-8° (picrate, m. 240-1°); 1-Me deriv., m. 159-60° (picrate, m. 263-4°); 1-Et deriv., m. 96-7° (picrate, m. 235-6°); 1-Pr deriv., m. 88-9° (picrate, m. 210-1°). C. J. WEST

Quinonediacridone derivatives. Indigo dyestuffs. V. V. SHARVIN AND D. I. GALPERIN. Moscow High Tech. J. Russ. Phys.-Chem. Soc. 60, 1493-9 (1928). Sharvin's method of quinonediacridone prepn. (C. A. 9, 3056) was slightly modified thus: The condensation product of *p*-benzoquinone with anthranilic acid in H_2SO_4 was poured in a porcelain dish and, after a current of steam had been passed over it for several hrs., abundant crystals of quinonediacridone sulfate pptd.; the latter on being decompd. by H_2O , gave crystd. quinonediacridone. If a strong current of Cl is passed for 2 hrs. into 1 part quinonediacridone in 50 parts $POCl_3$ contg. a few drops of HCl, and then the soln. is poured into cold water, an orange ppt. of the mono-Cl deriv. is formed. If instead of the Cl treatment the above soln. is refluxed for 2 hrs. with Br, the mono-Br deriv. is produced. No more than one Cl or Br atom can be introduced by this method. Both halogen derivs. are orange powders redder than diacridone, possessing properties very similar to the latter. While the attempts to obtain di- and tetra-Cl derivs. failed, dibromoquinonediacridone was prepd. by prolonged heating of quinonediacridone with an excess of Br in a sealed tube, and tetrabromoquinonediacridone was prepd. thus: 3.2 g. *p*-benzoquinone and 5.9 g. dibromanthranilic acid were gradually introduced into 50 g. boiling glacial AcOH and refluxed 5 hrs. giving a cryst. ppt. (small brown plates) of tetrabromoquinonediacridone with (yield, 40%). The crystals were heated in concd. H_2SO_4 3 hrs. at 200°, then dild. by H_2O , upon which tetrabromoquinonediacridone pptd.:

The ppt., washed with alkali, H_2O and EtOH, forms a dark red powder having solubilities and other properties similar to the non-brominated product; like the latter, it gives a cryst. sulfate and is reduced by hydrosulfite in presence of alkalis or Fe to a dihydro product (green-black), then into a tetrahydro deriv. (black violet). *p*-Aminoquinonediacridone was obtained thus: 3 g. dinitroquinonediacridone was triturated in a porcelain mortar with 20 g. cryst. Na_2S giving a black-blue paste which was dild. with 300 cc. H_2O and heated a few hrs. on a water bath; the amino deriv. is a dark lilac powder hardly sol. in $PhNO_2$, pyridine or glacial AcOH. With HCl or H_2SO_4 it gives dark green salts which only exist in presence of the acids and are hydrolyzed on being washed with H_2O . Dibenzoylaminoquinonediacridone was obtained on refluxing a mixt. of 1 g. diaminoquinonediacridone with 20 g. $PhNO_2$, 3 g. $BrCl$, 0.5 g. K_2CO_3 and some anhyd. $CuCl_2$; dildg. the reaction product with EtOH and filtering. Di-*o*-chlorobenzoyldiaminoquinonediacridone was prepd. in a similar manner by operating with *o*- $Cl_2C_6H_4COCl$, both the substituted and the non-substituted benzoyl chloride reacting with the 2 amino groups. The 2 products have very similar properties and present brown amorphous powders hardly sol. in $PhNO_2$ or pyridine. Dihydroxyquinonediacridone, obtained from the corresponding diamino product by diazotization, is a dark red powder dissolving with red color in concd. H_2SO_4 or in weak alkalis. It dyes wool in presence of NH_3 . Quinonediacridone and the above derivs., while stable and capable of reduction by hydrosulfite, do not possess the properties of indigo dyestuffs in view of the inability of their reduction products. They can be transformed into indigo dyestuffs by the introduction of the anthraquinone complex, thus forming compds. of the type $RNH.R'.NHR$, where R is the anthraquinone

complex and R' the quinonediacridone complex. As the halogen derivs. of anthraquinone do not react with diaminoquinonediacridone, *dianthraquinonyldiaminoquinonediacridone* was prepd. by heating a mixt. of 2 parts β -aminoanthraquinone and 1 part dibromoquinonediacridone in presence of C_6H_6 , anhyd. K_2CO_3 and anhyd. $CuCl_2$ for 20 hrs. After carefully washing the brown ppt., the latter was treated by hyposulfite in presence of alkalis and formed a red-brown soln. which, after filtration from a small quantity of undissolved powder, was pptd. by a current of air. It contained neither free amine nor Br and presented a cinnamon-colored indigo dyestuff. One part β -aminoanthraquinone was treated in the same manner with 4 parts tetrabromoquinonediacridone and also gave a dyestuff, but the latter contained Br. Both products were sol. with difficulty in C_6H_6 or pyridine and dyed cotton brown. B. N.

Pyrimidines. CV. A new test for thymine and 5-methylcytosine in the presence of uracil and cytosine. HENRY H. HARKINS AND TREAT B. JOHNSON. *Yale Univ. J. Am. Chem. Soc.* 51, 1237-42 (1929); cf. *C. A.* 23, 1905. —Thymine (0.01 g.) in 50 cc H_2O , is treated with Br until a red color is permanent; the excess of Br is then removed by boiling and to the soln. 1 g. $Ba(OH)_2$ crystals added, and the mixt. refluxed for 15 min. and then distd. $AcCH_2OH$ is found in the distillate and is tested for according to Baudisch (*C. A.* 13, 297). The test applies equally well to 5-methylcytosine; both pyrimidines can be detected in quantities as small as 1 mg. The test is applicable in the presence of uracil and cytosine. A synthesis for 5-methylcytosine is given. **CVI.** Leuco bases of a new class of dyestuffs containing pyrimidine rings. B. JOHNSON. *Ibid* 1274 G. — 2 Thiothymine aldehyde, $PhNMe_2$ and $ZnCl_2$, heated 4 hrs. at 100° , give 1.6 g. *p*-2-tetramethyldiaminodiphenyl-2-thiothymynylmethane, $NH.CS.NH.C[CH(C_6H_4NMe_2)]_2$ $CMcCO$, m 212.4° . *p*-2-Tetramethyldiaminodiphenyl-2-ethylmercaptothymynylmethane, m 218.9° . *p*-2-Tetramethyldiaminodiphenyl-thymynylmethane, m 197.8° . These undergo oxidation in acid soln., giving sol. dyestuffs which dye silk fiber with beautiful effects. These are being studied. C. J. W.

The constitution of nodakenin, a new glucoside from *Peucedanum decursivum* Maxim. I. JUNZO ARIMA. Keiogyaku Univ. and Kitasato Inst. for Infection Diseases at Tokyo. *Bull. Chem. Soc. Japan* 4, 16 (1929). — "Nodakenin" is a new glucoside, $C_{26}H_{34}O_8$, m. 215° , obtained from *Peucedanum decursivum* Maxim. It is hydrolyzed into 1 mol. of *d*-glucose and 1 mol. "nodakenetin," $C_{14}H_{14}O_4$, m. 185° . Nodakenetin is a neutral compd. insol. in cold alk. solns. It is not colored by $FeCl_3$, cannot be methylated, but gives a mono-Ac deriv., thus showing the presence of an alc. OH group. It has no MeO , CO nor CHO group. It dissolves in hot alk. solns. or alc. alk. solns. with a yellow color, and is recovered from these solns. by acid treatment. These properties, together with the esterification index show the presence of a lactonic group; the HO acid corresponding to the lactone cannot be obtained in a free state, but after prolonged heating with alc. KOH, another HO acid, m. 205.6° , is obtained and has been named "isonodakenetic acid." This is a monobasic acid, which gives a brown color with $FeCl_3$, and a di-Me deriv., m. 65.7° , with CH_2N_2 . The behavior of nodakenetin toward alkalis is very similar to that of the coumarin series. The KOH fusion of nodakenetin gives resorcinol, $AcOH$ and a new compd., $C_8H_6O_4$, m. $258-60^\circ$, showing thus the presence of a resorcinol radical, whose OH groups are linked to some other radicals, since nodakenetin exhibits no phenolic properties. From the above facts, it is concluded that the formula for nodakenetin must contain the groups indicated in I and also a nucleus similar to II.

ALBERT L. HENNE

Saponin of *Chamellia japonica* L. S. AOYAMA. *J. Pharm. Soc. (Japan)* 48, 717 (1929). — A study of the saponin of *Chamellia japonica* L. (I) was reported by

properties are: benzoylmonoacetylmapogenin, m. $150-65^\circ$; oxime of II, m. $175-97^\circ$. Hydrolysis of I, as proposed by A. is: $C_{26}H_{34}O_8 + 2C_6H_5O_2 + 3H_2O = C_{26}H_{34}O_4 +$

$8C_6H_{12}O_6 + 2C_4H_8O_4$. Oxidation of II gave an acid $C_{18}H_{30}O_5(CO_2H)_2$, m. 140° .

F. I. NAKAMURA

Metacholesterol bromide. I. LIPSCHÜTZ. *Arch. Pharm.* 266, 518(1929).—Metacholesterol dibromide is a colorless substance, m. 105° , and may be employed to demonstrate its dissimilarity to cholesterol dibromide. Metacholesterol and cholesterol are similar in character, but yield with Br 2 entirely different products.

Halogenation of organic compounds. I. G. FARBENIND A. G. Fr. 647, Jan 18, 1928. See Brit. 283,877 (*C. A.* 22, 4129).

Catalytic hydrogenation. GEORGES MIGNONAC. Fr. 647,080, May. Ac_2O is used as hydrogenation solvent when using insol. metals such as Ni, etc. Thus, primary amines are produced by hydrogenation of oximes or nitriles in the presence of Ac_2O , the amines being finally liberated from the acylated compds. or separated. Acetonitrile is hydrogenated in Ac_2O in the presence of Ni, giving ethyl amide. Propionitrile, capronitrile, benzonitrile and benzaldoxime are hydrogenated in the same way, giving the acetyl amine in each case. Acetophenone oxime gives the acetyl amine of α -phenylethylamine, and benzophenone oxime gives acetylbenzohydrylamine, m. 146° and b_p $164-165^\circ$.

Introducing aldehyde groups into cyclic compounds. I. G. FARBENIND A. G. Fr. 648,060, Feb. 1, 1928. An aldehyde group is introduced into carbocyclic and heterocyclic compds. contg. a labile H atom by causing these compds. to react with compds. of the general formula $HCONX^1X^2$ (where X^1 and X^2 represent H, or an alkyl, alkyl or aryl group), in the presence of condensing agents contg. Cl and more particularly with primary reaction products of formylic compds. and condensation agents contg. Cl, preferably with the addn. of an org. solvent. Aldehydes contg. Cl are obtained by reacting substances contg. a ketonic and methylenic group, in cyclic configuration and which can react in the tautomeric endic form, with formylic compds. of primary or secondary amines, in the presence of acid condensing agents contg. Cl. In examples anisole is added to a heated mixt. of formylmethylaniline and $POCl_3$, giving anisaldehyde. In the same way tetrahydro- α -naphthyl methyl ether gives a 1-methyltetrahydro-naphthaldehyde, m. $59-60^\circ$. The prepn. is also described of 2-methyl- (m. $52-53^\circ$) and 2-ethoxytetrahydro-naphthaldehyde (m. $62-63^\circ$), anthracene-9-aldehyde (m. 104°), xylyldehyde, 2-naphthal-1-aldehyde (m. 81°), 2,7-dihydroxy-naphthalene-1-aldehyde,

4,8-dihydroxy-1-naphthaldehyde, **2-hydroxynaphthalene-3-carboxyl-1-aldehyde**, **4-methyl-6-chloro-3-hydroxythionaphthene-2-aldehyde** (aldazine, m. 277–278°), **6-ethoxy-3-hydroxythionaphthene-2-aldehyde** (aldazine, m. 248°), **N-ethylcarbazoaldehyde** (m. 87°), **3,10-dichloro-9-anthracenealdehyde** (m. 174°), **1,5,10-trichloro-9-anthracenealdehyde** (m. 197°), **1,2-dimethoxy-** (m. 172°) and **2,6-dimethoxy-10-chloro-9-anthracenealdehyde** (m. 233°), and **naphthostyrylaldehyde** (m. 233°).

Esterifying aldehydes. JACQUES SCHALCH and JOHN W. OLSON (to Van Schaack Bros. Chemical Works). U.S. 1,708,902, April 9. In the production of EtOAc from acetaldehyde or in similar production of esters from aldehydes in the presence of Al ethoxide or other alkyl oxide of a trivalent metal, there is used as a promoter $Zn(NO_3)_2$ or other suitable nitrate of a metal the hydroxide of which is a weak base.

Aromatic amines. I. G. FARBENIND. A.-G. Brit. 297,212, Sept. 10, 1927. The catalytic reduction of $PhNO_2$ or other nitro compds. with H to form $PhNH_2$ or other aromatic amines is effected under at least 20 atm. pressure and in the presence of S compds. (which may be added or may be present in the raw materials) which partly poison the catalyst (which may be Swedish spongy iron) and thus prevent formation of undesired by-products. Cf. C. A. 23, 605.

Isothiourea ethers. SCHIERING-KAHLBAUM A.-G. Brit. 296,782, Sept. 9, 1927. Isothiourea ethers are made by reaction of a mercaptan with a cyanamide, preferably in an aq. or alc. medium, as by passing the mercaptan in vapor form into a cyanamide soln. With disubstituted cyanamides the reaction proceeds slowly without heating but rapidly at 100°. *S*-Ethylisothiourea is obtained from ethylmercaptan and cyanamide, *N*-ethyl-*S*-methylisothiourea from methylmercaptan and ethylcyanamide, and *N,N*-dimethyl(or diethyl)-*S*-methylisothiourea from methylmercaptan and dimethyl(or diethyl)cyanamide.

Diolefins. B. W. BYSOW. Brit. 297,231, Oct. 20, 1927. Vapors such as those of naphtha, naphtha fractions or naphtha residues are passed through a preheating zone at a temp. of 300–400° and then through a short heating zone at 750–1000° with or without use of catalysts such as strips of Fe, Ni or Al or pumice. The app. may comprise an Fe tube and a connected brass tube with a cooling jacket and internal concentric cooling tube.

Aliphatic anhydrides. HENRY DREYFUS. Fr. 647,227, Jan. 16, 1928. Aliphatic anhydrides, particularly Ac_2O , are obtained by submitting the vapor of the corresponding acid to a heat decompn. in the presence or absence of catalysts, and passing the gases leaving the reaction zone over water-fixing substances such as bisulfates, $CaCl_2$ and $ZnCl_2$ kept at a lower temp., preferably much lower, than that of the reaction zone. An example is given in which $AcOH$ vapor is passed through a Cu or clay tube at 800–1000° and then over $NaHSO_4$ or phosphoric acid at 150–350°.

Alkylated guanidines. SCHIERING-KAHLBAUM A.-G. Brit. 297,029, Sept. 12, 1927. Alkylated guanidines are produced by reaction of dialkylcyanamides with an amine salt in the presence of the corresponding free amine. Examples are given of the condensation of diethylcyanamide with $PhNH_2$ or isoamylamine in the presence of their hydrochlorides and of the condensation of dimethylcyanamide with isoamylamine or ethylamine in the presence of the hydrochlorides.

Anthrahydroquinones. I. G. FARBENIND. A.-G. Brit. 297,042, April 13, 1927. 2-Acylamino-9,10-anthrahydroquinone ethers and esters, in which the acyl group is the residue of an aliphatic carboxylic acid such as acetic or formic acid, are formed by the catalytic hydrogenation of a 2-acylaminoanthraquinone and etherifying or esterifying the resulting leuco compd., e.g., with Me_2SO , chlorosulfonic acid or Na chloracetate.

Anthraquinone derivatives. I. G. FARBENIND. A.-G. Brit. 297,001, Sept. 9, 1927. *o*-Halooanthraquinonecarboxylic acids are prepd. by treating an anthraquinone-*o*-sulfocarboxylic acid with halogen or a halogenating agent; examples are given of the prepn. of 2-chloroanthraquinone-1-carboxylic acid, 2-chloroanthraquinone-3-carboxylic acid, 1-bromo-3-chloroanthraquinone-2-carboxylic acid, 4-bromo-2-chloroanthraquinone-1-carboxylic acid and 3,7-dichloroanthraquinone-2,8-dicarboxylic acid. Anthraquinone-*o*-sulfocarboxylic acids are obtained by hydrolysis of *o*-cyanoanthraquinonesulfonic acids. Examples are given of the production of anthraquinone-1-carboxylic 2-sulfonic, 3-carboxylic 2-sulfonic, 1-bromo-2-carboxylic 3-sulfonic and 2,6-dicarboxylic 3,7-disulfonic acids. *o*-Cyanoanthraquinonesulfonic acids are prepd. from *o*-aminoanthraquinonesulfonic acids by the diazo reaction. Examples are given of the prepn. of 1-cyanoanthraquinone-2-sulfonic acid, 3-cyanoanthraquinone-2-sulfonic acid, 1-bromo-2-cyanoanthraquinone-3-sulfonic acid, 1-bromo-2-cyanoanthraquinone-3-sulfonic acid, 4-bromo-1-cyanoanthraquinone-3-sulfonic acid and 2,6-dicyanoanthraquinone-3,7-disulfonic acid.

Anthraquinone derivatives. I. G. FARBENIND. A.-G. Fr. 647,685, Jan. 25, 1928. Valuable new compds., the nature of which is not known, are obtained by causing ethylenediamine to react with hydroxyanthraquinones. In examples, ethylenediamine hydrate is added to (1) quinizarin and heated to 35–40°. Crystals giving an intense bluish red color when dissolved in H_2SO_4 are obtained; to (2) purpurin and heated to 90–95°, the product giving a blue color in H_2SO_4 ; to (3) 1,4,8-trihydroxyanthraquinone, the product giving a greenish blue color in H_2SO_4 ; to (4) 1,2,4,5,8-pentahydroxyanthraquinone, the product giving a green color in H_2SO_4 .

Naphthoquinone derivatives. ANDRÉ WAHL and ROBERT LANTZ (one-half to Soc. Anon. des matières colorantes et produits chimiques de Saint-Denis). U. S. 1,708,001, April 9. 4-Arylamino-1-arylimino- β -naphthoquinones are made by the action of a primary aromatic amine such as aniline or *p*-toluidine on a 1-aryliminonaphthoquinone such as 1-phenylimino- β -naphthoquinone.

Derivatives of phthalic acid. I. G. FARBENIND. A.-G. Fr. 7,513, Jan. 20, 1928. Derivs. of phthalic acid which are sol. in water are obtained by using ethylene oxide or its homologs to act on phthalic acid with or without a solvent and with or without a catalyst. In examples, a viscous liquid is obtained by heating in autoclave to 60–65° equal parts of ethylene oxide and phthalic acid. NaCl or Na phthalate may be used as a catalyst. The products are solvents and plastifying agents.

***N*-Hydroxyethyl derivatives of 2-amino-1-hydroxybenzene.** I. G. FARBENIND. A.-G. Brit. 296,309, Aug. 26, 1927. 2-Amino-1-hydroxybenzene is treated with ethylene oxide (suitably in the presence of $CaCO_3$ in aq. suspension) to form compds. such as 2-di(hydroxyethyl)amino-1-hydroxybenzene or *N*-monohydroxyethylamino-1-hydroxybenzene (details of the prepn. of which are given).

Chlorination products of methane. S. KARPEN & BROS. Ger. 472,421, May 2, 1925. See Brit. 245,991 (C. A. 21, 415).

Aromatic acid chlorides; ethyl chloride. VEREIN FÜR CHEMISCHE UND METALLURGISCHE PRODUKTION. Ger. 472,422, Dec. 30, 1923. The reaction between EtOH and $PhCCl_2$ is effected in the presence of Fe or $FeCl_3$, whereby EtCl and $PhCOCl$ uncontaminated with $PhCOOEt$ are obtained. Homologs or substitution products of $PhCCl_2$ may be treated in the same way.

Fatty acid salts. HOLZVERKOHLUNGS IND. A.-G. Ger. 472,123, Oct. 31, 1926. Solid salts of fatty acids are prepd. by sapon. fatty acid esters with carbonates or bicarbonates, in the presence of a little water, at a temp. above the normal b. p. of the ester and preferably under pressure. The reaction mixt. should be thoroughly agitated. The process may be applied in working up crude AcOH.

Anhydrous fatty acid salts. HOLZVERKOHLUNGS IND. A.-G. Ger. 472,124, Nov. 21, 1926. Addn. to 463,829. The method of Ger. 463,829 (C. A. 22, 4131) is modified, when using an anhyd. alkali metal hydroxide, by omitting the solvent and thoroughly agitating the reaction mixt.

Benzene synthesis. I. G. FARBENIND. A.-G. Brit. 297,179, July 13, 1927. C_2H_4 and its homologs are produced by treating mixts of C oxide and H at a temp. above 300° with a catalyst comprising Fe and then heating the resulting olefins and CH_4 hydrocarbons to 600–800° with or without a catalyst. A noble metal is preferably used with Fe in the first stage and, in the second stage, substances which would cause deposition of C are avoided. Cu, Sn, Zn or Cr may be used to line the app. or as catalysts.

Symmetrical arsenobenzenes. I. G. FARBENIND. A.-G. Brit. 296,327, May 27, 1927. Arseno compds. are formed by reduction, with Na hypophosphite and HCl, of 3-chloro-4-hydroxy-5-acetamidobenzene-1-arsonic acid (described in Brit. 230,487), 2-chloro-4-hydroxy-5-acetamidobenzene-1-arsonic acid, 3-methyl-4-hydroxy-5-acetamidobenzene-1-arsonic acid (described in Brit. 254,086; C. A. 21, 2533) and 2-methyl-4-hydroxy-5-acetamidobenzene-1-arsonic acid. The 2-chloro-4-hydroxy-5-acetamidobenzene-1-arsonic acid is obtained by nitrating 2,4-dichlorobenzene-1-arsonic acid, heating the product with KOH, reducing and acetylating. 2-Methyl-4-hydroxy-5-acetamidobenzene-1-arsonic acid is formed by nitrating 2-methyl-4-acetamidobenzene-1-arsonic acid, replacing the acetamino group by OH by heating with KOH, reducing and acetylating.

Dichloroaminomethylbenzenes. I. G. FARBENIND. A.-G. Fr. 648,070, Feb. 1, 1928. 2,3-Dichloro- and 2,5-dichloro-4-amino-1-methylbenzenes are prepd. by treating 2-chloro-4-acetamido-1-methylbenzene with Cl at a low temp. and in the presence of AcOH contg. water, and sapon. the 2,5-dichloro-4-acetamido-1-methylbenzene which is pptd. in a pure state during the chlorination, and the 2,3-dichloro-4-acetamido-1-methylbenzene which is pptd. from the mother liquor by the addn. of water.

Purifying anthracene. DEUTSCHE HYDRAWAXWERKE A.-G. Ger. 472,183, Feb. 2, 1922. Addn. to 301,651. Crude $C_{14}H_{10}$ is purified by treatment with hydrogenated

$C_{10}H_8$, and a reagent for removing carbazole. Examples are given in which the purification is effected (1) by treatment at 100° with $C_{10}H_{12}$ and pyridine, the purified $C_{10}H_8$ sepd. on cooling; (2) by boiling with $C_{10}H_{12}$ and KOH, filtering the pptd. K-carbazole, and cooling the filtrate; (3) as in (1), but with MeCOEt instead of pyridine.

Acetic acid. H. SUIDA. Brit. 296,172, July 18, 1927. In extn. of HOAc from aq. solns. by treating the vapor with solvents of higher b. p. than HOAc as described in Brit. 230,447 (C. A. 19, 3272), there are used as solvent esters of cyclic carboxylic acid with mono- or polyhydroxy alcs. such as the Me, Et and Bu esters of the naphthene acids and of phthalic acid and the hexyl, heptyl, glycol and glycerol esters of phthalic acid. Cf. C. A. 23, 608.

Acetic acid. HOLZVERKOHLUNGS IND. A.-G. Ger. 472,399, Dec. 9, 1924. Concd. AcOH is recovered from dil. aq. solns. by evapg. the soln., passing the vapors over or through an adsorbent, *e. g.*, C, and recovering AcOH from the charged adsorbent by means of the vapor of an org. liquid easily separable from AcOH. It is better to use the vapor of an org. liquid forming a const. boiling mixt. with water, particularly AcOEt. Cf. C. A. 23, 1141.

Acetic acid. I. G. FARRENIND. A.-G. Fr. 647,682, Jan. 25, 1928. Dil. AcOH is concd. by adding alkyl acetic esters, or mixts. thereof with hydrocarbons or halogen derivs. of hydrocarbons, to lower the b.p. of the water, and rectifying. Examples are given in which AcOEt, AcOEt and C_4H_6 , AcOEt and $C_2H_4Cl_2$ are added. Cf. C. A. 23, 850.

Acetic acid. SOC. ANON. DES DISTILLERIES DES DEUX-SEVRES. Brit. 296,974, Sept. 10, 1927. HOAc is extd. from its aq. solns. by a solvent having a b. p. above that of HOAc but below 150° , such as AmOAc, which is insol. in water and will not form an azeotropic mixt. with HOAc. Water is then removed from the ext. by use of an auxiliary entraining liquid such as EtOAc which forms an azeotropic mixt. with water but not with HOAc, and the dried soln. is finally distd. to recover anhydrous HOAc and solvent. Various details of app. and procedure are described.

A derivative of isopropylallylbarbituric acid. J. HOFFMANN-LA ROCHE & Co. A.-G. Ger. 471,655, Nov. 1, 1921. Equimol. amts. of the acid and 1-phenyl-2,3-dimethyl-4-dimethylamino-5-pyrazolone are melted together.

Benzyl naphthalenesulfonic acids. I. G. FARRENIND. A.-G. (Karl Daimler and Gerhard Balle, inventors). Ger. 472,289, May 2, 1926. Addn. to 436,881. The method of prepg. benzyl naphthalenesulfonic acids described in Ger. 436,881 is improved by conducting the reaction between naphthalenesulfonic acids and $PhCH_2Cl$ at a temp. below 100° and in the presence of a considerable excess of H_2SO_4 . Products which do not discolor textiles are so obtained.

Phthalic anhydride. THE SELDEN CO. Fr. 647,880, Jan. 14, 1928. Phthalic anhydride prepd. by the catalytic oxidation of $C_{10}H_8$ is purified by heating it to boiling, with or without pressure and with or without condensation and polymerization catalysts such as MnO_2 , SiO_2 or zeolites, and (or) superheated steam, or treating the vapor thereof in this way.

Ethyl acetate. FRED C. ZEISBERG (to E. I. du Pont de Nemours & Co.). U. S. 1,708,460, April 9. EtOH vapor is passed over a dehydrogenation catalyst at a temp. of 250 – 500° and under a pressure above 10 atm., producing EtOAc and some assocd. products including normal BuOH. As catalysts, there may be used metals such as Cu, Ni, Co and Fe, alone or in admixture or with addns. of oxides such as those of Mn, Cr, Mg or Ca, or oxides alone may be used such as those of Zn, Mg, Cr or Mn.

Dibenzyl phthalate. ADOLPH ZIMMERLI (to Rhodia Chemical Co.). U. S. 1,708,404, April 9. Phthalic anhydride is dissolved in an excess of benzyl alc., the soln. is heated and subjected to gentle boiling for about 8 hrs., distd. to remove water, and the residue is subjected to a vacuum to distil off excess benzyl alc.

Methanol synthesis. HENRY H. STORCH (to Roessler & Hasslacher Chemical Co.). U. S. 1,707,331, April 2. A catalyst comprising Cu and Ce fluoride or other rare earth fluoride is used in the synthesis of MeOH from H and CO. Cf. C. A. 22, 3893.

1-Phenyl-2-methylaminopropanol. E. MERCK, CHEM. FAB. Ger. 472,466, Feb. 3, 1927. See Brit. 284,644 (C. A. 22, 4540).

Cresols. SCHERING-KAHLBAUM A.-G. Brit. 297,083, Sept. 14, 1927. *m*-Cresol is sepd. from mixts. such as those contg. also *p*-cresol by treatment with urea which forms an addn. product with *m*-cresol which is sepd. in cryst. form and then decomposed by use of water, dil. inorg. acids or solns. of $MgSO_4$ or Na_2SO_4 (any urea remaining in the *m*-cresol being decomposed by hydrolysis). Various details of procedure are given.

Menthol. HOWARDS & SONS, LTD., AND J. W. BLAGDEN. Brit. 297,019, June 8, 1927. Synthetic menthol is subjected to partial esterification (with aliphatic or aro-

matic acids or anhydrides), the unesterified portion is sepd. from the esterified portion and the latter is saponified; the parent material is thus divided into fractions of higher and lower m. p. than the starting material. A similar result is obtained by partially saponifying a menthol ester, sepg. the liberated menthol from the unsaponified ester, and saponifying the latter. Various details are given.

Paraformaldehyde. I. G. FARBENIND. A.-G. Brit. 296,847, July 1, 1927. Paraformaldehyde is obtained from the products resulting from the catalytic oxidation of MeOH by washing the products (preferably after cooling) with a warm strong soln. of CH_3O . An inert gas such as N may be added to the reaction products prior to or during washing, and it is preferred to cool the products only to such an extent that the temp. of the washing liquid is maintained sufficiently high to preclude the deposition of paraformaldehyde in the liquid during the washing process. CH_3O in the residual gases is recovered by washing with water. Cf. C. A. 22, 3171.

Fatty acids. HOLZVERKOHLLUNGS-INDUSTRIE A.-G. Fr. 647,219, Jan. 16, 1928. See Can. 284,062 (C. A. 23, 605).

11—BIOLOGICAL CHEMISTRY

PAUL E. HOWE

A—GENERAL

FRANK P. UNDERHILL

A non-specific pressor substance. J. B. COLLIP. *Trans. Roy. Soc. Can.* 22, 181-4(1928).—Potent pressor exts. have been made from skeletal muscle, liver, kidney, spleen, ovary, testis, stomach, intestine, whole fetus, and several com. preps. of both pepsin and pancreatin. The tissue is thoroughly minced and extd. with neutral or acidulated H_2O at boiling temp. for 5 min., the ext. filtered and the filtrate condensed *in vacuo* to a sirup. Add abs. $(\text{CH}_3)_2\text{CO}$ and shake violently. Allow the layers to sep., remove the acetone layer, again ext. the saline layer with $(\text{CH}_3)_2\text{CO}$, repeat several times, combine the $(\text{CH}_3)_2\text{CO}$ exts., filter and evap. *in vacuo* almost to dryness. Again ext. with abs. $(\text{CH}_3)_2\text{CO}$ and repeat as often as necessary to ensure removal of practically all inorg. and most of the depressor substances. The pressor principle is believed to be the same in all exts. so made from the different tissues. It is sol. in abs. alc., and in mixts. of $(\text{CH}_3)_2\text{CO}$, $(\text{C}_2\text{H}_5)_2\text{O}$ and H_2O . It can be fractionally pptd. from mixts. of abs. alc. and petroleum ether by addn. of the latter. The potency of the exts. is destroyed by addn. of Ac_2O . The active principle is removed by adsorption on norit at p_{H} 8 and is released by treating the norit with boiling water acid to Congo red. Intravenous injection of the exts. is followed by a rather sudden rise in blood pressure with a concomitant increase in lung ventilation. Intravenous injection of cocaine diminishes or abolishes the pressor effect; atropine is without effect; gynergen enhances the effect.

A. T. CAMERON

A bio-hydrographical investigation of the sea adjacent to the Fraser River mouth. II. Factors affecting the distribution of phytoplankton. A. H. HUTCHINSON. Univ. B. C. *Trans. Roy. Soc. Can.* 22, Sec. V, 293-309(1928); cf. C. A. 22, 1598. A. T. C.

Correlations between the total nitrogen of the bases and arginine nitrogen and between total nitrogen of the bases and lysine nitrogen, of various proteins. RALPH K. LARMOUR. Univ. Minnesota. *Trans. Roy. Soc. Can.* 22, Sect. V, 349-63(1928). From data for total basic N and arginine N taken from 214 analyses of various plant proteins the coeff. of correlation was $+0.794 \pm 0.017$. The coeff. of correlation between total basic N and the deviation of the arginine N from its most probable value, the mean, was $+0.211 \pm 0.044$. The coeff. of correlation between total basic N and lysine N was $+0.548 \pm 0.032$, and the coeff. of correlation between total basic N and the deviation of lysine N from its mean was $+0.03 \pm 0.046$. The data are considered to be indirect evidence in support of Kossel's hypothesis that arginine is the nucleus of the protein mol.

A. T. CAMERON

The occurrence of α - and β -glucosidase in taka-diastase. AKISUKE MATSUMOTO. *Acta Schol. Med. Univ. Imp. Kioto* 10, 285-6(1928).—Taka-diastase causes the hydrolysis of maltose, amygdalin, and salicin. It therefore contains maltase (α -glucosidase and also emulsin (β -glucosidase)).

DAVID DAVIDSON

A new enzyme. R. FOSAY AND A. BRUNEL. *Compt. rend.* 198, 426-8(1929).—The seeds of many plants such as *Soya hispida*, *Phaseolus vulgaris*, *Phaseolus lunatus* contain an enzyme capable of hydrolyzing allantoin to allantonic acid. The latter is identified as xanthylallantonic acid. The authors suggest the name "allantoinase" for this enzyme.

DAVID DAVIDSON

Fermentation problems. H. v. EULER AND K. MYRBÄCK. Univ. Stockholm. *Z. physiol. Chem.* 181, 1-14(1929).—Mainly a review of the phosphorylation and aldehyde mutation theory of alc. fermentation. The view is upheld that Robison's hexose-monophosphate is an intermediate in the formation of Harden's hexosediphosphate. The aldehyde mutation of the hexose is believed to occur after formation of the monophosphate. The presence of cozymase is essential for the aldehyde mutation and for the formation of diphosphate. The mutation of glucose is not in the strict sense a Cannizzaro reaction, since there is no formation of alc. (sorbitol) and acid (gluconic acid), but rather a shifting of energy from 1 part of the mol. to another, such as might result from migration of a H atom within the mol. itself. Without addn. of phosphate the fermentation begins sooner but does not attain the max. velocity of the fermentation with added phosphate. Neuberg's expts. where the initial fermentation velocity of hexosemonophosphate was as great as that of glucose are explained on the assumption that a pure substance was not used, since the Ba salt of the ester from which the Na salt was prepd. had a rotation of $27-8^\circ$ instead of 13° as found by Robinson and by the authors. Although the utilization of carbohydrates by yeast, muscle, and lactic and propionic acid bacteria requires the presence of cozymase, certain AcOH bacteria are lacking in cozymase and their fermentation of carbohydrate is not facilitated by addn. of cozymase from another source. In normal fermentation where dismutation is followed by cleavage into 3-carbon compds. no noteworthy quantity of AcOH is formed.

A. W. DOX

γ -Butyrobetaine, crotonbetaine and carnitine in the animal metabolism. WILHELM LINNEWEH. Univ. Würzburg. *Z. physiol. Chem.* 181, 42-53(1929).—After subcutaneous injection of 20 g. γ -butyrobetaine during 6 days, there was recovered from the dog's urine 40% of the unchanged substance, 3% as carnitine and a small amt. of NMe₃. A similar expt. with crotonbetaine yielded 33% of the original substance and about 0.2% of carnitine. Carnitine itself gave a recovery of 30%, but no oxidation products were found. The greater yield of carnitine (β -hydroxy- γ -butyrobetaine) from the satd. as compared to the unsatd. betaine is in harmony with Dakin's observation on the relative rates of oxidation of PhC:CCO₂H, PhCH:CHCO₂H and PhCH₂CH₂CO₂H. The pharmacol. effect of γ -butyrobetaine on mice consists in accelerated respiration, salivation, dilation of pupils, lachrymation, clonic convulsions, vaso-constriction, paralysis of motor nerve endings, defecation and finally death with the heart in diastole. The lethal dose is 70-80 mg. for a 15 g. mouse. Crotonbetaine gives the same curare-like symptoms but the lethal dose is somewhat smaller, 60-70 g. as the HCl salt. Carnitine, on the other hand, is non-toxic.

A. W. DOX

Carnitine, crotonbetaine and γ -butyrobetaine in putrefaction. WILHELM LINNEWEH. Univ. Würzburg. *Z. physiol. Chem.* 181, 54-7(1929).—Putrefaction of carnitine in the presence of glucose, Witte peptone and putrid pancreas for 3 weeks gave 95% γ -butyrobetaine and 1.2% NMe₃. Crotonbetaine under similar conditions yielded 70% γ -butyrobetaine and a trace of NMe₃. Probably carnitine is first formed by addn. of H₂O to crotonbetaine at the double bond before reduction to γ -butyrobetaine occurs. The base isolated by Brieger from the putrefaction products of horse meat and later recognized as γ -butyrobetaine was probably a reduction product of the carnitine originally present.

A. W. DOX

The question of the occurrence of methylguanidine in the animal organism. II. An attempt to separate methylguanidine from carnosine and creatinine. I. A. SMORODINTZEV AND A. N. ADOVA. Univ. Moscow. *Z. physiol. Chem.* 181, 77-82(1928); cf. C. A. 23, 1920.—After an involved series of pptns. with Hg salts and extns. with EtOH, an ext. of dog muscle finally yielded creatinine as the ZnCl₂ salt, and methylguanidine as the picrate.

A. W. DOX

Biological importance of sterols. ADOLF WINDAUS. *Pharm. Monatshefte* 10, 34(1929).—An address.

W. O. E.

Porphyrin-modalities. A. A. HIJMAN V. D. BERGH, P. MULLER AND A. J. HIJMAN. *Proc. Acad. Sci. Amsterdam* 32, 15-19(1929); cf. C. A. 23, 161.—Koproporphyrin, derived from etioporphyrin III, was obtained from a patient with porphyria. This is the first time that this substance has been shown to exist in nature, although it has previously been made synthetically.

ARTHUR GROLLMAN

Composition of bone. VII. Equilibration of serum solutions with secondary calcium phosphate. M. J. SHEAR, MARTHA WASHBURN AND BENJAMIN KRAMER. Jewish Hospital of Brooklyn. *Science* 69, 835-6(1929); cf. C. A. 22, 4328.—Equilibration of serum with CaHPO₄ always caused an increase in the concn. of the Ca or P or both, in all solns. with $[Ca] \times [P] < 45$. The mean value obtained for K'_{CaHPO_4} was 3.2×10^{-4} at room temp. and 3.4×10^{-4} at 38° .

ARTHUR GROLLMAN

A study of factors said to influence the nitrogen distribution of gelatin. FLOYD S. DART. Carlsberg Lab., Copenhagen. *Biochem. J.* 23, 149-60(1929).—Preliminary treatment of gelatin with acid or alkali has no effect on the percentages of non-amino N and of basic N.

BENJAMIN HARROW

Some influences of light on biochemical reactions. W. B. OSBORN. Univ. of the Witwatersrand. *J. South African Chem. Inst.* 12, 25-32(1929).—A survey chiefly concerned with the treatment of certain diseases by sun light. ALBERT L. HENNE

Differences observed in the conditions of the sea water at the margins of two opposing tidal currents. T. G. THOMPSON AND R. C. MILLER. Univ. of Washington. *Science* 68, 517-18(1929).—Analysis made on two samples of water taken from two opposing currents in the channel north of San Juan Island showed that in samples of water but a few feet apart there was a difference of 2.4° in temp., of 0.22 in p_H and of 2.8 parts per thousand in Cl. There were differences in sp. gr. and total CO_2 . It is suggested that such changes are of considerable biological importance. G. H. W. L.

The effect on the solubility of sparingly soluble calcium salts of proteins and the carbon dioxide-binding capacity of proteins. WOLFGANG PAULI AND THEODOR STENZINGER. Inst. med. Kolloidchemie, Wien. *Biochem. Z.* 205, 71-103(1929).—The solv. of $CaSO_4$ is markedly increased by the presence of proteins in this order: serum albumin, pseudoglobulin, hemoglobin. This effect is attributed to an equiv. inactivation of Ca^{++} and SO_4^{--} ions, probably because of the formation of multivalent amphoteric ions with protein. The considerably increased adsorption of Ca when protein is shaken with $CaCO_3$ is regarded as due to the formation of Ca proteinate as a result of hydrolysis of $CaCO_3$, and is therefore followed by a much increased cond., by an increased migration to the anode and a marked diminution in the heat and alc. coagulability. Correspondingly, the strongly acid serum albumin gives these reactions with $CaCO_3$ more than the other protein, which behavior is the exact opposite of that with $CaSO_4$. Evidence is also offered to show that proteins, especially the very acid neg. ovalbumin, become electropositive under the influence of CO_2 . This, however, is not through the formation of a dicarbonic acid (Siegfried's carbaninic acid) but of a compound of the NH_4HCO_3 type. S. MORGULIS

A new enzyme, glucosidase. IL. D. MÖLLER. Kgl. Landhauhochschule, Kopenhagen. *Biochem. Z.* 205, 111-43(1929); cf. *C. A.* 23, 160.—The press juice of *Aspergillus niger*, as well as alc., alc.-ether or acetone ppts. of the press juice, contains an enzyme that oxidizes glucose with the absorption of atm. O_2 . The glucose is oxidized to gluconic acid, as is evident both from the relation between the acid formation and the absorption and from the loss of glucose in relation to the acid formation. About 20% of the acid produced was isolated and detd. as the Ca compd. Expts. have shown that only 20% of this acid can be recovered from a soln. contg. proteins. The enzyme is designated glucose-oxidase, but it is not established whether or not it is a glucose dehydrase. The enzyme preps. from *A. niger* give off a very small amt. of CO_2 , which apparently has nothing to do with the sugar destruction. The enzyme oxidizes principally glucose, but in small amts. also mannose and galactose. However, it has no effect on fructose, xylose, arabinose, Ca gluconate, dihydroxy-acetone, glycerol or acetaldehyde. *A. niger* cultured on a mannose medium yields enzyme preps. with no greater oxidative power against mannose, and with the same glucose-oxidase content. Cultivated on fructose it contains the glucose-oxidase but no enzyme effective against fructose; this is also true for tartaric acid or glycerol cultures, which contain only the gluconoxidase. In a H atm. the enzyme has no effect on glucose. The optimum H⁺ ion concn. for its action is at p_H 5.5-6.5. The glucose-oxidase action increases from 0 to 30°, but the Q_{10} falls from 1.6 to 1.1. The temp. at which the enzyme is killed is 73°. The glucose-oxidase action is unaffected by the addn. of PO_4 ions or insulin. The enzyme rapidly loses its activity, and at 20° it is 75% inactivated in 2 1/2 hrs. The glucose-oxidase is present also in the press juice of *Penicillium glaucum*. S. M.

The behavior of insulin toward x-ray, radium and ultra-violet radiations. D. DEN HOND, S. E. DE JONGH AND A. E. J. PARK. Pharmako-Therapeutic Lab., Amsterdam. *Biochem. Z.* 205, 144-53(1929); cf. *C. A.* 22, 3894.—When air is absolutely excluded insulin is unaffected either by x-ray, Ra or ultra-violet radiations. Even in the presence of air x-rays have no effect whereas Ra radiations of even smaller energy content than the x-rays do weaken the insulin. Ultra-violet radiation destroys insulin to a great extent especially if there is a trace of O_2 in the aq. soln. In phenol soln. the insulin is unaffected. S. MORGULIS

The splitting of adrenaline in serum. M. CHIKANO AND M. KOMINAMI. Med. Acad., Osaka. *Biochem. Z.* 205, 176-9(1929).—The adrenaline content of serum was detd. by the chem. method of Chikano and these results were compared with detns.

made by biol. methods (blood pressure measurement in rabbits). The splitting of adrenaline in serum follows a very definite curve as can be detd. by either the chem. or the biol. method. Expts. with phosphate buffers of the p_H of blood show that the splitting of adrenaline proceeds with the same velocity as in serum. In Locke's soln. the splitting of adrenaline is considerably slower. It is thought that the PO_4 ions play an important role in the splitting of the adrenaline.

S. MORGULIS

The mode of action of animal phosphatase in stereochemical relations. ANTONIO GUALDI. Kaiser Wilhelm Inst. für Biochem., Berlin-Dahlem. *Biochem. Z.* 205, 320-4(1929).—Phosphatase from rabbit liver hydrolyzes the salts of *dl*-bornyl phosphate asymmetrically just as the plant phosphatase does.

S. MORGULIS

Diffusion of hemoglobin. R. E. LIESEGANG AND O. MASTBAUM. Univ. Frankfurt, a. M. *Biochem. Z.* 205, 451-6(1929).—The rate of diffusion of hemoglobin in a 10 or 20% gelatin soln. is discussed.

S. MORGULIS

Effect of hydrogen ions on the function and swelling of nerves. E. E. GOLDENBERG. State Inst. for Brain Research. *Zhurnal expl. Biol. Med.* 10, 622-30(1929).—The function of nerves ceases the more quickly the lower the p_H of its medium, and at $p_H = 1$ the function is lost in less than 5 mins. The curve of swelling rises rapidly at first, then more slowly. The swelling min. lies in a weakly acid medium.

S. M.

The neutralizing action of the nerve. E. E. GOLDENBERG. State Inst. for Brain Research. *Zhurnal expl. Biol. Med.* 10, 632-6(1929).—Nerves placed in an acid NaCl soln. cause the reaction to shift to the alk. side. The change in the p_H is greatest in slightly acid solns.; in strongly acid soln. the shift may not occur.

S. MORGULIS

Cozymase in yeast. KARL MYRBÄCK. *Svensk Kem. Tids.* 42, 3-8(1929); cf. *C. A.* 22, 3670. —The most convenient source for cozymase is brewer's yeast. The content is variable; that of good yeast is 100 units per g. dry wt. (cf. *C. A.* 18, 3064 and many subsequent abstracts of v. Euler and Myrbäck on nomenclature and assay methods). It gives pentose reactions but is not pptd. by $CuSO_4 + Cu(OH)_2$. It dialyzes, is destroyed on autolysis and by high temp. and prolonged heating. The yeast is repeatedly washed with water and then pressed to a 25% moisture cake. The press-cake is beaten up in 4 parts water at 80° for 10 mins. and centrifuged, then evapd. in vacuum and dialyzed. The liquid is purified with $Pb(AcO)_2$, excess Pb removed as PbS and the H_2S by aeration. The cozymase is pptd. by $Hg(AcO)_2$ and freed again with H_2S . $HgCl_2$ does not ppt. it. There is a 90% recovery. The best preps. are 80,000 units per g. dry wt.

A. R. ROSE

The increase in the viscosity of protoplasm due to the temperature and its relation to biological reactions. JAN BÉLEHRÁDEK. Univ. Masaryk, Brno. *Protoplasma* 3, 317-26(1928).—The formula $y = (a/X^b)$, where y is the time taken to obtain a certain result, X the temp., and a and b are consts., was applied to the pulsations of the heart of the cladoceran *Daphia*, b was identified as a measure of protoplasmic viscosity. When transferred suddenly from 15° to 4° the frequency of pulsations of *Daphia* heart diminished slowly in a regular curve and came to an equil in about an hr. The beat returned to normal in about 5 mins. when placed at room temp. Conclusion:—In the cooling a time factor intervened like that found in the change of viscosity as certain colloidal solns. are cooled.

M. H. SOULE

The viscosity of protoplasm. GERTRUD MISSBACH. *Protoplasma* 3, 327-44(1928).—Ions act on protoplasmic viscosity in the order monobasic < dibasic < tribasic. The action of Al is studied in particular.

M. H. SOULE

Influence of temperature on dispersion and flocculation of egg albumin. I. S. U'ZINO. Univ. Kyoto. *Kolloid-Z.* 47, 244-8(1929).—The opalescence of albumin sols contg. alc. increases when the temp. is raised or the alc. concn. increased. In protein + H_2O + NaCl + alc. systems, flocculation is the more complete the higher the NaCl concn. Opalescence is more pronounced at higher temp., while the stability is greater.

B—METHODS AND APPARATUS

STANLEY R. BENEDICT

Detection of plasmochine. W. SCHULEMAN, F. SCHÖNHÖFER AND A. WINGLER. *Abh. Gebiete Aussenchemie* 26, n. II, 5 pp.(1928).—Plasmochine is detected in urine-free aq. soln. at a concn. of 1 in 2×10^5 by the development of a blue color with tetrachloro-

benzoquinone. Reaction with K mercuri-iodide, which is not specific, is sensitive to 1 in 10^4 . B. C. A.

A new respiration apparatus. ERNST SIMONSON. Abt. Arbeitsphysiol. Sozialhyg. Untersuchungsamtes, Frankfurt a. M. *Arbeitsphysiologie* 1, 224-57(1928).—The respiration app. is one of the open-circuit type for humans; it consists of mouthpiece, inspiratory and expiratory valves, a special aliquoting device and dry gas meter. The analyses of the aliquot sample are made with the Haldane app. Between the expiratory valve and the gas meter is a metal tube in which there is a circular baffle plate with a hole 8.66 mm. diam. The baffle plate provides enough resistance so that air is forced through capillary metal side tubes attached to the main metal tube between expiratory valve and the baffle plate. The cross sections of the capillary tubes can be varied and to them are attached rubber bags which hold 700 cc. without significant pressure. The aliquoting device is light enough to be carried on the back of the subject and therefore is suitable for studies in industrial work. No significant loss of CO_2 takes place if the duration of the periods is 15 mins. or less, but samples must be drawn from the rubber bags into glass containers if the analyses cannot be made immediately. A detailed discussion of the accuracy of the aliquoting system is given. Expts. were made with rubber materials, oiled paper, treated linen, and "cellophan" either with or without impregnation with com. liquids, and "cellophan" was found to be the most impermeable to CO_2 . The article concludes with a table of the comparative applicability and cost of several well-known methods of detg. the respiratory exchange of man. T. M. C.

Colorimetric estimation of cystine in urine. P. CRISTOL AND C. BENOIT. *Bull. soc. sci. med.* 8, 246-7(1928); *Physiol. Abstracts* 13, 243.—Colorimetric reading of cysteine (transformed from cystine) in cyanide medium, and observations of the influence of Na_2SO_3 on the blue color produced by uric acid, have led to the conclusion that colorimetric extn. of cystine by Looney's method is subject to numerous errors. H. L. D.

Estimation of sugar in urine by means of fermentation tubes. HANS MELCHER. *Apoth.-Ztg.* 44, 305(1929).—An experimental study showing that the Lohmstein type of fermentation saccharometer yields exact quant. results, provided due regard be given to the following requirements: Both the Hg (5 g.) and yeast (0.2 g.) must be accurately weighed; the urine should not be dild. with H_2O , but rather with normal urine; the fermentation should continue over a period of 9-10 hrs. at 37° . W. O. E.

Technic for Leishman's stain suitable for "field" application. J. C. CHUKERBUTI. Indian Military Hospital, Risalpur. *Indian Med. Gaz.* 63, 578(1928).—Directions are given for prepg. stained films suitable for the detection of malaria parasites and their effects upon cellular elements. This method is not suggested as an improvement on the historical Leishman's technic, but as a rough field method to be utilized where pure distd. H_2O free of CO_2 is difficult to obtain. FREDERICK G. GERMUTH.

A simplified bedside blood-sugar method. HARENDRA N. MUKHERJEE. Calcutta Michael Med. Coll., Calcutta. *Indian Med. Gaz.* 63, 624-6(1928).—A method is described for the estn. of blood sugar at the bedside of the patient. The detn. can be made with app. that a medical practitioner is expected to possess. The outlined procedure is a modification of the Polin (1928) method. The blood sugar is oxidized by alk. $\text{K}_3\text{Fe}(\text{CN})_6$ soln., and the ferrocyanide produced is measured colorimetrically as Prussian blue. The color so obtained is 5 times as intense as the tints observed when alk. Cu soln. is employed. The advantages of this method are: no special apparatus is necessary; a very small amount of blood (about one-fiftieth of a ml.) is sufficient. The results attained are accurate for clinical work. FREDERICK G. GERMUTH.

A new test for albumin in urine. CHUNILAL BORA. *Indian Med. Gaz.* 64, 17-18(1929).—The reagent used for the new test consists of saccharin in H_2O , prepd. by boiling the sulfinate in the solvent until a supersatd. soln. is obtained. The test is performed in the same manner as Heller's HNO_3 test. The reagent whose utilization is advocated possesses certain advantages over the HNO_3 test in that it fails to ppt. mucin, urea or urates. The presence of mucin in urine complicates the employment of the acetic acid test, while picric acid ppts. peptones and allied bodies. Comparative results obtained by the application of each of the 4 methods upon urine and other body fluids are presented in a table. The constitution of the compd. produced by the interaction of saccharin with albumin is unknown. FREDERICK G. GERMUTH.

A simple method for estimating blood cholesterol. G. FETTICH. *Klin. Wochenschr.* 8, 362-3(1929).—Mix 1 cc. serum with 0.2 cc. 25% KOH. Boil for 3 mins. Cool. Shake for 3 mins. with 5 cc. CHCl_3 . Filter. Mix two cc. of the filtrate with 0.5 cc. Ag_2O and 0.1 cc. H_2SO_4 . Compare the green color obtained with that of a standard prepd. in the same manner. MILTON HANKE.

Hemorrhage hyperglucemia. MICHAEL G. MALINOS. Columbia Univ. *Am. J. Physiol.* 86, 70-3(1928).—A marked rise in samples of blood sugar was noted after the withdrawal of about 16 cc. of blood per kg. of animal. The adrenals were not concerned in this rise of blood sugar. It may be due to diln. of the blood by tissue fluid richer in glucose than blood itself.

J. F. LYMAN

The use of nitrogen for determining the circulatory minute volume. E. K. MARSHALL, JR., GEORGE A. HARROP, JR. AND ARTHUR GROLLMAN. Johns Hopkins Univ. *Am. J. Physiol.* 86, 99-109(1928).—Circulatory rate was calcd. from the rate of N_2 elimination while the subject was breathing O_2 . A new method was devised for detg. N_2 in the presence of O_2 and CO_2 by use of the Van Slyke-Neill manometric gas analysis app. The soly. of N_2 in blood was 0.90 cc. per 100 cc. of blood. The results of applying the method in general lead to doubts as to the reliability of the method.

J. F. LYMAN

The time necessary for rebreathing in a lung-bag system to attain homogeneous mixture. ARTHUR GROLLMAN AND E. K. MARSHALL, JR. Johns Hopkins Univ. *Am. J. Physiol.* 86, 110-6(1928).—When a normal subject expired, to his residual air and then rebreathed from a rubber bag contg. 2.4 l. of a 5% mixt. of H_2 in air, equil. between the pulmonary gases and the mixt. rebreathed was attained in 15 secs. during which time about 5 deep respirations were made.

J. F. LYMAN

A method for the determination of the circulatory minute volume in man. E. K. MARSHALL, JR. AND ARTHUR GROLLMAN. *Am. J. Physiol.* 86, 117-37(1928).—The subject rebreathes a mixt. of ethylene and air or N_2O and air contained in a rubber bag of 2.5-3 l. capacity. Samples of gas for analysis are taken 15 secs. after the beginning of rebreathing and 12 secs. later. If A = difference in O_2 of 2 samples, B = difference of inert gas, C = cc. inert gas sol. in 100 cc. of blood and D = av. % inert gas during the expt. Then cc. of O_2 absorbed by 1 l. of blood during the expt. = $(A/B) \times C \times (D/100) \times (P/760)$. The O_2 absorbed by the subject per min. is detd. The min. circulatory vol. is then obtained by dividing this value by the O_2 absorbed by 1 l. of blood. Detns. on 16 normal persons in the sitting posture and under basal conditions gave values ranging from 3 to 5 l. Duplicate detns. on the same individuals always agreed within 10%.

J. F. LYMAN

Electron equilibria in biological systems. II. The simultaneous automatic recording of electrical potential and muscular contraction. FLOYD DE EDS, SAMUEL ROSENTHAL AND CARL VOGTLIN. U. S. Pub. Health Service. *Am. J. Physiol.* 86, 200-14(1928).—Methods and app. for continuous and simultaneous recording of muscular contraction and the potential changes in the muscle are described. Contraction was accompanied by a sharp fall in potential and relaxation was characterized by a building up of potential.

J. F. LYMAN

The hormone of the adrenal cortex. F. A. HARTMAN, K. A. BROWNELL, W. E. HARTMAN, G. A. DEAN AND C. G. MACARTHUR. Univ. Buffalo. *Am. J. Physiol.* 86, 353-9(1928).—Hashed adrenal cortex from cattle was shaken with 3 vols. of H_2O from 15 to 30 mins., then 0.1 N AcOH added to pH 4.4 to 4.9 and clarified by centrifugalization. The AcOH ext. was satd. with NaCl at pH 5.4 and the ppt. washed in the supercentrifuge with satd. NaCl soln. to remove adrenaline. The ppt. was dissolved in 0.9% NaCl so that 1 cc. contained the material from 1 g. of cortex and the pH adjusted at 7.35. Adrenalectomized cats showed an av. survival period of 31.1 days when treated with subcutaneous injections of *corlin*; untreated cats lived an av. of 5.7 days.

J. F. LYMAN

The reduction of *m*-dinitrobenzene as an index of the respiratory exchange of tissues and as a function of the pH. M. COMEL. *Boll. soc. ital. biol. sper.* 3, 919-21 (1928); cf. *C. A.* 22, 4605; 23, 163.—Four hundred mg. of muscle pulp was mixed with 100 mg. of finely powd. *m*-dinitrobenzene; the material was placed in a test tube and 2 cc. of phosphate buffer soln. of varying pH values was added. The mass was mixed, allowed to stand for 3 hrs., filtered and the pulp washed with 2 cc. more of the same phosphate soln. The filtrates were combined and the intensity of the color was detd. by Bürker's colorimeter. The color of the filtrate having a pH of 7.0 was given a value of 100. Filtrates of lower pH were compared to this. The results are given in tabular form showing (x) the pH of the phosphate soln., (x') the pH of the mixt. of the buffer and tissue pulp, and (y) the intensity of the color. By plotting (y) as a function of (x') the data fit approx. the hyperbolic curve $y = (a/x') + b$. There is, therefore, a parallelism between the reduction of *m*-dinitrobenzene, the respiratory exchange of tissue pulp and the pH of the pulp. The reduction of *m*-dinitrobenzene as an index of the respiratory exchange of tissues, the pH and the duration of the reducing period. *Ibid* 922-5.—The mixt. of tissue pulp and buffer soln. was allowed to stand for 30 mins.

and for 1 hr. The intensity of color was detd. as described above. The velocity of reduction of *m*-dinitrobenzene was affected by time in a different degree for the different p_H values. This was especially evident at lower p_H , e. g., at p_H 3.1, the intensity of reduction was 20% for $\frac{1}{2}$ hr., 26% for 1 hr. and 33% for 3 hrs. Expts. were then made by allowing tissue pulp at p_H 7.0 to stand varying periods of time. The reduction was proportional to the time only up to the 2nd hr. at the end of which it had reached a value close to the max. obtained at 3 hrs. The increase in reduction at 3 hrs. in comparison to that at the end of the $\frac{1}{2}$ hr. was 108% at p_H 7.0; 133% at p_H 5.8; 145% at p_H 5.2; 144% at p_H 4.1; 250% at p_H 3.1. These results show a different velocity of reduction at different p_H values which run parallel to the respiratory exchange of the tissues, and also a diminution of the reducing process at p_H 7.0 compared with lower p_H . The reduction of *m*-dinitrobenzene as an index of respiratory exchange of the tissues, p_H and temperature. *Ibid* 925-7.—The influence of temp. on the velocity of reduction of *m*-dinitrobenzene by muscle pulp was investigated. The technic already described being used, muscle pulp of varying p_H values was incubated at 20°, 30° and 40° for 3 hrs and the formation of *m*-nitrophenolhydroxylamine was detd. colorimetrically. The exptl. results indicated that the reduction of *m*-dinitrobenzene at varying p_H values does not follow the same curve at different temp. The diminution of the velocity of reduction at p_H below 7.0 is marked at 20°, more marked at 30° and very rapid at 40°. This behavior runs parallel to the respiratory exchange of tissue at the same temp. Also in *Arch. sci. biol.* 13, 158-84(1929).

PETER MASUCCI

A new test of renal function. R. T. BRAIN AND H. D. KAY. The London Hosp. Quart. J. Med. 22, 203-16(1929).—A new test for renal efficiency, the glycerophosphate test, is described. It depends on the excretion of extra P in the urine in the hour following the intravenous injection of a standard quantity of P in the form of Na glycerophosphate (550 mg.). In normal individuals, or in patients not suffering from renal disease, at least 150 mg. of extra P is excreted in this period; in cases of renal impairment the amt. varies from this figure down to 0, depending on the amt. of renal damage. The test is simple and does not possess as many errors as does the blood urea concn or the phenolsulfonephthalein test. The glycerophosphate test agrees very closely with clinical findings when the latter are typical, and if it diverges from the urea or phenolsulfonephthalein tests it agrees more closely.

JOHN T. MYERS

The determination of levulose in small quantities of blood. S. VAN CREVELD. Univ. of Amsterdam. Arch. nederl. physiol. 13, 521-33(1928).—The proteins were removed from the blood by the addn. of 1 part of 4% HCl and 2 parts of 5% HgCl₂ to 1 part of blood. To 1 cc. quantities of the filtrate were added 8-10 drops of a mixt. of diphenylamine and HCl. The material was then boiled. A blue color developed in the presence of levulose due to the reaction of this substance with the reagents. The color was compared with standard solns. of levulose. The outstanding advantage of this method is the small amount of blood (1 cc.) necessary for a detn. M. H. S.

A new method for preparing gold sol. O. WUTH. Munch. med. Wochschr. 75, 472-3(1928).—Pure chemicals and clean glass are essential. Preliminary process. To 100 cc. distd. H₂O there are added 1 cc. of 1% AuCl₃ and 2 drops of a 0.4% alc. soln. of phenol red. Sufficient K₂CO₃ (3% soln.) is added to produce a clear pink color which persists for 60-90 mins.; this is usually about 0.5 cc. Prepn. of gold sol. To 250 cc. of distd. H₂O are added 2.5 cc. AuCl₃ and the quantity of K₂CO₃ required in the preliminary process. After this has been well shaken, 1 drop of 0.1% tannic acid soln. is added and the whole heated to boiling (brisk). It is removed from the flame and 1.5 cc. of a 2.5% formaldehyde soln. is quickly added. The mixt. is stirred continuously until the color changes into a deep, clear red. The temp. must be kept near the boiling point until this change takes place. The sol. should be tested biologically with known cerebrospinal fluids before being used. This method gave gold sol. 50 times without a single failure.

R. C. WILLSON

The determination of catalase. P. GOLYZOV AND V. JANKOVSKI. Russk. fiziologicheskij Zhurnal 11, 33-41(1928); Ber. ges. Physiol. expil. Pharmacol. 46, 401. After testing experimentally several of the methods now used for the detn. of catalase, the authors conclude that the permanganate method of A. Bach and S. Zubkows in its original form is usually the most suitable test. To det. the active catalase number or index this method is altered in that 40-60 mg. H₂O₂ are used instead of 20 mg. To blood solns. which have been warmed to room temp. it is necessary to add a small amt. of ethyl alc. (1:8000) about 30 mins. before the catalase detn. to activate the inactive catalase.

R. C. WILLSON

Modified I₂O₅ method for determination of CO in air and blood (MARTINEK, MARRY) 7.

 KÖHLER, A.: Handbuch der biologischen Arbeitsmethoden. Section II. Physiological Methods. Part 2, No. 6, Photomicrography. Berlin: Urban & Schwarzenberg. 287 pp. Reviewed in *Abstract Bull. Kodak Res. Labs.* 15, 144 (1929).

C—BACTERIOLOGY

CHARLES B. MORREY

Growth of *Bacterium radicola*. S. SNIESZKO. *Bull. intern. acad. Polonoise* 1928B, 55-74.—*B. radicola* from kidney bean, red clover, cultivated pea and hairy vetch does not grow on a synthetic medium of p_H above 7.0 or below 4.5. The H-ion concn. exerts considerable influence on the morphological changes observed in *B. radicola*.
 B. C. A.

Behavior of bacteria in milk. G. DEI GRISOGONO. *Zymologica* 3, 113-5(1928).—The existence of Gorini's two types of coagulation of milk (C. A. 21, 935, 3066) is confirmed. Organisms causing the first type of coagulation do not liquefy gelatin, whereas those producing the second type liquefy gelatin distinctly and rapidly. The only strain of streptococcus isolated from milk belongs to the second class.
 B. C. A.

Thermophilic and thermoduric microorganisms with special reference to species isolated from milk. V. Description of spore-forming types. PAUL S. PRICKETT. N. Y. Agr. Expt. Sta., *Tech. Bull.* 147, 5-58(1928).—Four hundred and eighty cultures were isolated from milk. The thermophilic bacteria are responsible for the production of pin-point colonies on nutrient media seeded with pasteurized milk. The source of these organisms is hay, straw, grain and equipment. These organisms produce undesirable changes in pasteurized milk that affect its com. life and salability. No evidence was adduced tending to show any public health significance.
 C. R. F.

Symbiotic gaseous fermentation (by bacteria). ALDO CASTELLANI. *Rev. hyg. med. prev.* 51, 232-40(1929).—The phenomenon is described wherein 2 bacteria, neither of which alone is able to ferment carbohydrates, are able to produce gas when grown in symbiosis. *B. typhosus* in symbiosis with *B. morgani* ferments maltose, mannitol or sorbite, yet neither organism alone attacks these sugars. *B. typhosus* alone produces only acid, while *B. morgani* alone produces neither gas nor acid. This phenomenon may be employed in the differentiation of various species of bacteria, for example, the 3 dysentery groups. Similarly, carbohydrates may be identified by employing the proper test organisms.
 C. R. F.

New ways for sterilization. RUDOLF DECKWITZ. *Klin. Wochschr.* 8, 342-8 (1929).—This is a good historical discussion of the concept of oligodynamic action. The original work discussed in this paper deals largely with the practical application of a highly dispersed metallic Ag prepn (solid, not colloidal) to water sterilization. This prepn. is so effective that when kept in contact with the bacteria it is capable of sterilizing emulsions contg. 100,000 colon bacilli per cc. in 10 mins. The expts. reported are too numerous and varied to be reported in abstract form.
 MILTON HANKE

Electrical phenomena of some species of *Leptospira*. W. AEG. TIMMERMAN. *Nederland. Tijdschr. Hyg., Microbiol. en Serol.* 3, No. 3, 241-7(1928).—Several species of *Leptospira* show a positive elec. charge in regard to the dil. rabbit serum in which they are grown. The measured cataphoretic speed is partly influenced by the displacement of the *Leptospira*. By adding CNS ions, it is possible to reverse the elec. charge in regard to this serum.
 J. C. JURRENS

Bacterial antagonism with special reference to the effect of *Pseudomonas fluorescens* on spore-forming bacteria of soils. I. M. LEWIS. Univ of Texas. *J. Bact.* 17, 89-103(1929).—*Pseudomonas fluorescens* produces a thermostable, filterable, dialyzable bacteriotoxin which is both inhibitory and bactericidal. The toxin is not sp. in its action but is more active against certain species than others. Fungi are more resistant than bacteria. Spore-forming bacteria and micrococci are very sensitive, while colon bacilli are resistant. The substance is not iso-inhibitory. The amt. of toxin produced depends on the compn. of the medium and the availability of O. Max. production occurs on sloped cultures on Uachinsky's agar. The toxin persists longer in agar than in broth cultures, and resists desiccation for long periods of time. It is sol. in alc. and is adsorbed by substances in soil and by charcoal. It is formed in sterilized manured soils inoculated with *Ps. fluorescens*. Alc. exts. from such soils are inhibitory for the more sensitive species only. Soils which have supported a vigorous growth of *Ps. fluorescens* in flask cultures are suitable for the growth of *B. cereus* after sterilization.

Samples of soil from fields, gardens, pastures and meadows failed to yield toxins by similar methods of extn. It appears that the toxin here studied is of a different nature from that of the thermolabile substances reported by others from soils. J. T. M.

Smooth-rough variation in bacteria in its relation to bacteriophage. F. M. BURNET. Lister Inst. *J. Path. Bact.* 32, 15-42(1929).—From most cultures that are rough by all the usual criteria it is possible to derive smooth forms by the use of suitable phages since certain phage types attack only smooth forms, others only rough strains and some attack both forms. Some rough forms could not thus be converted to smooth forms and the evidence suggests that the conversion can only occur when a trace of smooth antigen is retained in the antigenic makeup of the bacillus. It is suggested that bacterial resistance to phage is dependent in large part on the bacterial constituent which functions as the "heat-stable antigen." JOHN T. MYERS

Notes on intestinal bacilli with special reference to smooth and rough races. P. BRUCH WHITE. Natl. Inst. Med. Research, London. *J. Path. Bact.* 32, 85-94(1929).—The sol. specific substance may be extd. quantitatively from *Salmonella* and similar bacilli by hot dil. acid. Rough variants give an immediate reaction with Millon's reagent; smooth races react only when the sol. specific substance has been removed. Under ordinary circumstances of test, smooth bacilli of this group and filtrates of broth cultures are more toxic to lab. rodents than the corresponding rough forms. When the rough forms are treated with alc. their toxicity approaches that of the smooth forms. Mucoid growth in *Salmonella* is not related to smoothness and is not analogous to capsule formation. JOHN T. MYERS

The formation of optically active lactic acid from glucose and *dl*-lactic acid by bacteria. HIDEO KIMURA. Univ. Kyoto. *Acta Schol. Med. Univ. Imp. Kyoto* 11, 325-33(1928).—Degradation of glucosamine by *Bacillus prodigiosus* and *B. subtilis* yields *l*-MeCH(OH)CO₂H (I), while with *B. coli* *d*-MeCH(OH)CO₂H (II) is formed (Takao, C. A. 18, 2354). K. investigated the action of these bacteria on glucose and *dl*-MeCH(OH)CO₂H (III). A 2-day old culture of the bacteria was added to a soln. contg. 5.0 g. NaCl, 2.0 g. KH₂PO₄, 0.1 g. MgSO₄, 1.0 g. (NH₄)₂CO₃, 5 g. CaCO₃, and 3-20 g. of the substrate per l. The mixt. was kept at 37° for a certain period, after which it was examd. for MeCH(OH)CO₂H. In the expts. with glucose and *B. prodigiosus* or *B. coli* I was obtained. Glucose and *B. subtilis* yielded at certain times II and at other times III. In the expts. with III it was observed that all 3 species of bacteria chiefly utilized the *d*-form. G. SCHWACH

Initiation of growth of certain facultative anaerobes as related to oxidation-reduction processes in the medium. RENÉ DUBOS. Rockefeller Inst. Med. Research *J. Exptl. Med.* 49, 559-73(1929); cf. C. A. 23, 1929. The growth of many pathogenic organisms in plain meat infusion broth is possible only when a large inoculum is used. This requirement is much less strict when the broth cultures are incubated (a) under anaerobic conditions, (b) in fresh media very recently boiled or autoclaved, (c) in fresh media reduced by means of H₂, or to which small amts. of cysteine or of blood have been added. It is suggested that these findings can be accounted for by assuming that the bacterial species under consideration can multiply only in media, the oxidation potential of which is below a critical value. The favorable growth conditions obtained by the procedures enumerated above may be attributed to the establishment of a proper reduction potential in the medium; the same result is obtained by using a large inoculum, owing to the reducing properties of bacterial cells. C. J. WEST

Relation of the bacteriostatic action of certain dyes to oxidation-reduction processes. RENÉ DUBOS. Rockefeller Inst. Med. Research. *J. Exptl. Med.* 49, 575-92(1929). Oxidized indophenol and methylene blue are bacteriostatic for pneumococcus and hemolytic streptococci of human and bovine origin, while the indigos, malachite green and litmus are not toxic. 2-Chloroindophenol, the most positive of the indicators of oxidation-reduction potentials used, is also the only one to have a bacteriostatic action on cheese strains of *Streptococcus hemolyticus*. Methylene blue and the indophenols are no longer bacteriostatic when present in a reduced form in a medium capable of maintaining them in such a condition. A comparison of these results with the growth in plain broth of the organisms studied suggests that the "inhibiting" dyes "poison" the medium at an oxidation potential outside the range in which the inhibited organism can grow. The validity of this hypothesis is discussed and the significance for the use of dyes in therapeutics is considered. C. J. WEST

Cheshire cheese. I. Bacterial content (SADLER) 12. Fixation of atmospheric N by *Azotobacter* (MEYERHOF, BURK) 15. The bactericidal action of smoke (as used in smoke-curing of fish) (HESS) 12. •• Metabolism of conifer leaves. J. DOYLE AND P. CLINCH. *Proc. Roy. Irish Acad. B*, 38, 116-127(1928).—Peroxidase, sometimes accompanied by an alc. sol. inhibitor, has been identified as the sole oxidizing enzyme in the leaves of conifers. Expts. have failed to establish a relationship between the p_H and the water-sol. pentosan fraction of the leaves.

B. C. A.

Catalase content of conifer leaves. J. DOYLE AND P. CLINCH. *Proc. Roy. Irish Acad. B*, 38, 128-47(1928).—The seasonal variation in the catalase content of conifer leaves is described and appears to be assocd. with the corresponding variation in starch content. The variations of the initial rate of the catalase activity with temp., enzyme and substrate concn. have also been detd.

B. C. A.

Composition of tobacco leaves. A. I. SMIRNOV, M. A. DRBOGLAV AND L. S. ERIGIN. U. S. S. R. State Inst. Tobacco Invest. 1928, *Bull.* 46, 1-59; cf. *C. A.* 23, 1929.—The variation in tobacco leaves with age has been detd. with reference to the following: dry wt., rate of respiration, total carbohydrate, sucrose, maltose, starch, dextrin, invertase, amylase, total N, protein, nicotine, amide N and hydroxy-acid contents.

B. C. A.

The transpiration ratio of farm crops and pasture plants in the Adelaide district. A. E. V. RICHARDSON AND H. C. TRUMBLE. *J. Agr. S. Australia* 32, 224-44(1928).—The av. transpiration ratio for cereal crops for a period of 3 years for dry matter and grain, resp., is: barley 339:828; wheat 328:1147; oats 379:1146; rye 469:1586. The transpiration ratio for cereals and pasture plants varies with the stage of growth. Grasses and clovers transpire relatively small quantities of H_2O in the early stages of growth. Absorption of nutrients by the roots is independent of the transpiration stream, for with barley the greater part of the N and mineral nutrients are absorbed at a comparatively early stage of growth, while transpiration increases exponentially and reaches a max. just after flowering. The application of sol. P results in a marked reduction of the transpiration ratio of certain plants. This effect is particularly marked in the early stages of growth and varies with the degree to which the soil is satd. with H_2O .

M. S. ANDERSON

A biochemical study of some soil fungi with special reference to ammonia production. A. K. THAKUR AND ROLAND V. NORRIS. *J. Indian Inst. Science* 11A, Part 12, 141-60(1928).—Fifty distinct species of fungi were isolated from soils and a part of these was used for subsequent studies. *Aspergillus flavus*, *Penicillium glaucum* and *Armillarius* were tested for N-fixing power and showed negligible fixation. A study of cellulose decompn. by 12 different soil fungi showed wide variation in the powers of the different organisms, varying from no decompn. to very strong action. Decompn. of org. matter in artificial media by *Aspergillus flavus* was studied with and without the presence of sugar. Total N, available N, ammoniacal N and p_H were detd. at frequent intervals over a period of 40 to 60 days. The chem. data as well as growth observations showed that the accumulation of NH_3 from the result of mold action took place at different stages in the life cycle of the organism. Amidase was isolated from *Aspergillus flavus*, and its influence on the rate of hydrolysis of amino acids and amides was studied. The reaction was autocatalytic in nature; the velocity curve first exhibited a period of lag, and then a period of acceleration as NH_3 was formed.

M. S. ANDERSON

The relation of nitrogen metabolism to plant succulence. W. H. PEARSALL AND JAMES EWING. *Ann. Botany* 43, 27-34(1929).—Radish and turnip were grown in 2 series of sand cultures watered with solns. contg. 1-2 mg. and 100 mg. of nitrate, resp. $NaNO_3$, $Ca(NO_3)_2$ and NH_4NO_3 were employed singly or in mixt., but gave results of similar character. Analyses of the plants were made at 5 and 8 weeks of age. In both radish and turnip the plants receiving low N supply had higher insol. N, lower sol. N, lower amino and amide N, higher total sugars, higher H-ion concn. and lower water content than those with high N supply. The total titratable acidity is higher in the high N series, but is chiefly due to amino acids, so that the actual acidity is lower. The

accumulation of amino acids under high N supply appears so to affect metabolism as to reduce acid production. The reduction of H-ion concn. thus brought about permits greater swelling of the protoplasmic colloids, which have a point of min. swelling at about pH 5.3-5.4. JOSEPH S. CALDWELL.

The phosphate requirement of barley at different periods of growth. WINIFRED E. BRENCHELY. *Ann. Botany* 43, 89-110(1929).—Cultures of Goldthorpe barley were grown in nutrient solns. with and without P (266.7 p. p. m. P_2O_5 were present in the complete soln.). At intervals of 2 weeks groups of plants were transferred from the P-free soln. to one contg. P, and a second group was transferred from complete to P-free medium. This gave 2 series grown, respectively, with and without P for 2, 4, 6, 8, 10, 12, 14 and 16 weeks, each then receiving the reverse treatment until harvest. Two addnl. groups were started with and without P, the treatments being reversed at 2-week intervals throughout their growth, so that each had P available for half its total growth period. Tiller production is detd. by the availability of P_2O_5 in the first 6 weeks of life, no tillering occurring in plants deprived of it for this length of time. If P_2O_5 is available for the first 4-6 weeks and is then removed, tillering continues for 2-3 weeks longer, then ceases and is not resumed when P_2O_5 is again supplied. Ear formation was not affected by deprivation of P_2O_5 after the end of 6 weeks, but deprivation for the first 4 weeks entirely inhibited ear formation. If P_2O_5 were supplied for the first 6 weeks, grain formation was little affected by its subsequent withdrawal, but deprivation in the first few weeks suppressed grain formation despite presence of adequate supplies later. Total dry weight was not reduced by withholding P_2O_5 after the first 6-8 weeks. The critical period in the life of the barley plant in relation to P supply is the first 6 weeks. JOSEPH S. CALDWELL.

Physiological studies in plant nutrition. 1. The effect of manurial deficiency on the respiration and assimilation rate in barley. F. G. GREGORY AND F. J. RICHARDS. *Ann. Botany* 43, 119-61(1929); cf. *C. A.* 22, 3904.—Four groups of plants of barley, variety Plumage Archer, were grown in sand cultures supplied with complete fertilizer, N deficient, K deficient and P deficient. Detns. of amt. of CO_2 given off or taken up were made on each group of plants at 4-day intervals from June 8 to August 18, employing Waller's katherometer. Various defects of the original instrument, with the methods adopted for remedying them, are stated. The respiratory rate of the K-deficient plants was markedly higher, that of N-deficient plants considerably lower, at all stages of growth than that of fully manured plants; that of P-deficient plants was quite irregular, exceeding the rate of plants on complete fertilizer in the first 4 weeks and again in the ninth to twelfth weeks of the expt. but falling below in the fifth to ninth weeks.—In all the plants with incomplete manurial treatments, the respiratory rate falls to a min. with a subsequent rise; with complete fertilizer it falls to a rate which remains const. after the first 5-6 weeks. The results with light of high and low intensity differ in that the rate of respiration falls off more sharply with increasing age under light of low intensity. JOSEPH S. CALDWELL.

The effect of small electric currents on the assimilation of *Elodea canadensis*. D. MARX. *Ann. Botany* 43, 163-72(1929).—Currents of densities varying between 1.5 and 6×10^{-7} milliamps. per sq. cm. were passed through the water in which the plants were growing, care being taken to protect the plants against the products of electrolysis. No increase in assimilation rate as measured by the bubble method was observed in any instance but a c. d. of about 1 milliamp. per sq. cm. caused a marked decrease in assimilatory rate. JOSEPH S. CALDWELL.

Susceptibility of wheat to mildew as influenced by carbohydrate supply. SAM F. TRELRASS AND HELEN M. TRELRASS. *Bull. Torrey Bot. Club* 56, 65-92(1929), cf. *C. A.* 22, 1378.—Detached leaves of wheat seedlings, previously depleted of carbohydrate by keeping in darkness, were inoculated with *Erysiphe graminis* and placed in 0.1 M solns. of various carbohydrates and alcs. In all of these, susceptibility was markedly increased, most in dextrose, levulose, sucrose and melzitose, somewhat less in xylose, galactose, lactose, maltose and glycerol, least in arabinose, rhamnose, mannose, starch, dextrin, inulin and mannitol. Even in the last named, growth and spore formation were more than 100-fold that on control leaves in tap water. In leaves placed in a series of sucrose solns. kept in darkness, development of mildew increased with increase of concn. up to 27.57 g. per 100 cc. Development of mildew increased with increase in osmotic concn. of sucrose, dextrose or glycerol up to about 19 atms., but fell off above this point. Mildew did not develop on leaves kept in light in chambers kept free of CO_2 unless the leaves were supplied with a carbohydrate soln. J. S. C.

The existence of resins in *Stigmatocystis nigra*. V. CHARLES POSTILLON. *Compt. rend.* 188, 413-6(1929).—The mycelium was washed with H_2O , dried and extd.

for 8 hrs. with EtOH. After cooling, the ext. was decanted from a ppt. and dild. to 70% EtOH, boiled to agglomerate the fat which was sepd. H₂O was then added in excess, the mixt. boiled and a drop of HCl added to coagulate the ppt. which was identified as a resin. The same result was obtained by means of Na₂CO₃ or Mg salts. The presence of a resin was confirmed by dissolving the fatty acids in Ac₂O, adding H₂SO₄, and obtaining a fugitive red or bluish violet color followed by a yellow-brown which was fluorescent.

DAVID DAVIDSON

Colorimetric determination of total phosphorus in plant solutions. R. W. GERDEL. Ohio Agr. Expt. Sta. *Ohio J. Sci.* 28, No. 4, 229-35(1928).—Although not as reliable as the usual volumetric methods, P may be detd. by a colorimetric method on the wet-digested dry samples. Hydroquinone seems the best colorimetric reducing agent for (NH₄)₂PO₄·12MoO₃. The color developed is neither proportionally nor geometrically progressive, consequently table or curve corrections cannot be made. The presence of H₂SO₄ and other compds. in the plant solns. interferes with the accuracy. R. C. E.

The determination of the freezing point of sugar-cane buds. G. L. FAWCETT. *Rev. Ind. Agr. Tucuman* 19, 123-31(1928).—The first application of the thermoelec. method for this purpose. A Cu-constantan thermocouple was made, the directions of Taylor being followed, and a Leeds Northrup potentiometer was adopted. Care was taken against supercooling. The f. ps. are: apple -1.93°, peach -1.44°, orange -2.21°, potatoes -1.78°, ripe tomatoes -0.90°, lettuce -1.0°, vetch -1.09°. The value for sugar-cane buds varied from -1.1° to -2.4°. The resistance of buds to cold seems to vary, possibly with evapn. The interior tissue of shoots freeze more easily than the buds.

S. L. B. ETHERTON

Nitrogen and carbohydrate distribution in organs of bearing apple spurs. A. E. MURNEK. Mo. Agr. Expt. Sta. *Research Bull.* 119, 3-50(1928).—The chem. compn. of leaves, new growth, and reproductive organs of bearing apple spurs of the Jonathan, Paynes, Late Keeper and King David varieties were ascertained at 15- to 30-day intervals during 1 season and 5- to 6-day intervals during another. Detns. were made of fresh and dry wts., total sugars, starch, hemicellulose, H₂O-sol. N, insol. N and total N. Characteristic chem. changes are correlated with specific functional activities and the attendant morphological development. Throughout the considered period and probably till the fruit attains full growth, the reproductive organs seem to dominate, directly or indirectly, the metabolism of the bearing spur complex. Flowering is characterized by marked increase in all active forms of carbohydrates and N. In the opened flowers in particular, total sugars and sol. N show very high percentages. An increase in these org. substances being likewise noted elsewhere in the spur at this time, translocation to the floral parts must have been very rapid. The sudden increase in sugars at full bloom most likely resulted from hydrolysis of starch, but a considerable fraction of sol. carbohydrates was supplied by hemicellulose, which shows a conspicuous drop at this period. The significance of hemicellulose as an available form of carbohydrates is emphasized. Not only sol. but total N as well comes to a max. concn. in the organs at flowering. Hence nitrogenous substances are moved into the bearing spur in abundance during fertilization and fruit setting. Both carbohydrates and N seemingly are reabsorbed from the dropping blossoms preparatory to their abscission. The former is again deposited largely as hemicellulose or as starch in the leaves and the new growth of the spur. N seems to return primarily to the foliage. Considerable quantities of org. substances, however, are lost through the various drops. After flowering the direction of movement of most org. compds. is to the fruits that have set. Throughout the growing season the total amts. of carbohydrates and N show an ever-increasing accumulation in the fruit. However, as a result of the rapid enlargement in vol. and increase in dry wt. of this organ, the % concn. of some of the nitrogenous substances naturally decreases. Hemicellulose accretion reaches a max. in the fruit in mid-summer, thence decreasing rapidly. Thus, in addn. to starch, hemicellulose must be considered a source of sugars for the flesh of the apple. The development of both leaves and fruit is characterized by an accumulation of N in H₂O-insol. form. Early in the season more total N is formed in the leaves than in the young fruit. As soon as the latter begins to develop this situation is reversed. Throughout its growth the fruit shows conspicuously higher % distribution of the total H₂O-sol. N and hence, in aggregate, more developmental activity than any other organ. Late in the season, however, the fruit is likewise a carbohydrate organ of incomparably larger vol. and higher concn. of sugars, starch and hemicellulose than the vegetative parts of the bearing spur system. Eighteen references are cited and discussed.

C. R. F.

Chemical studies of grape pigments. II. The anthocyanins of Clinton grapes. R. J. ANDERSON AND FRANK P. NAEHHAUER. N. Y. Agr. Expt. Sta., *Tech. Bull.* 146,

3-12(1928); cf. *C. A.* 21, 98, 3929.—The Clinton grape is a cultivated variety of *V. riparia* but probably also contains some blood of *V. labrusca*. The pigment occurring in Clinton grapes consists principally of a monoglucoside, anthocyanin. The anthocyanin chloride, $C_{25}H_{35}O_{11}Cl$, did not sep. in definitely cryst. form, but the picrate, $C_{25}H_{35}O_{11}C_6H_2(NO_2)_3OH$, crystd. in bright red prisms or needles. The glucoside is easily hydrolyzed by boiling HCl, yielding 1 mol. each of glucose and anthocyanidin chloride, $C_{17}H_{15}O_7Cl$, the latter crystg. from the hot soln. in prisms. The anthocyanidin chloride consists largely of a monomethyl ether of delphinidin, but the values for methoxyl were too high, indicating that it contained some delphinidin dimethyl ether. The absorption spectra of anthocyanin chloride and anthocyanidin chloride consist of 1 broad band extending from the yellow into the blue. III. The anthocyanins in Seibel grapes. R. J. ANDERSON. *Ibid* 13-21.—The anthocyan occurring in Seibel grapes is a monoglucoside and appears to be identical with oenin, the glucoside derived from *Vitis vinifera*. The pigment was isolated as the picrate which crystd. in red needles. The anthocyanin chloride crystd. in long prisms and corresponds to the formula $C_{25}H_{35}O_{11}Cl \cdot 3H_2O$. The anthocyanidin chloride, $C_{17}H_{15}O_7Cl + 1.5H_2O$, crystd. in prisms from the hot soln. on boiling the glucoside with 20% HCl. The values obtained for methoxyl indicate that the anthocyanidin consists largely of a dimethyl ether of delphinidin, but evidently some monomethyl ether of delphinidin is also present. The substance is very similar to or identical with the oenin obtained by Willstätter and Zollinger from *V. vinifera* (*C. A.* 11, 1408). The absorption spectra of the glucoside and of the sugar free pigment consist of 1 broad band extending from the yellow into the blue. Attention is drawn to the fact that in a cross between European and American varieties of grapes, such as the Seibel seedlings, the pigment peculiar to *V. vinifera* is inherited by the hybrid.

C. R. F.

Pineapple investigations. H. C. HENRICKSEN. Porto Rico Agr. Expt. Sta., *Rept.* 1927, 19-24.—Moisture content, sap reaction, carbohydrates, proteins, enzymes and inorg. substances in the pineapple leaf were studied in an effort to det. the causes of certain outward discernible differences in the pineapple plant. In the normal leaf, the approx. H_2O content was 91% in the white-base leaf, 85% in the middle section and 80% in the section adjoining the apex. Reddish colored leaves had less than 80% of H_2O . The pH value of the normal sap varied from 6 to 6.3. Carbohydrates in young leaves were 13% while in red senescent leaves the value reached 30-40%. The normal leaves contained much starch while the chlorotic leaves contained very little. Chlorotic pineapple leaves were considerably higher in mucilaginous substances which indicates that starch formation inhibited in the chlorotic leaf and explains the greater amt. of gum formation in such leaves. Mature leaves were in normal condition when the carbohydrate content was 3-4 times as high as the protein content. The average protein content was 6%. A high protein-carbohydrate ratio was always correlated with low chlorophyll, and a high reducing sugar content was correlated with a high anthocyan content. The normal pineapple leaves contain peroxidase, catalase, reductase and diastase in greater amts. than red and chlorotic leaves. $(NH_4)_2SO_4$ used as a fertilizer produced normal vigorous leaves while either $NaNO_3$ or KNO_3 produced abnormalities such as pale color, twisted and crinkled leaves and fruit and few or no slips. Expts. indicate that P is required only in very small quantity and its use is valuable only in obtaining early maturity of the leaf tissue. S is useful as a soil amendment but the use of S is not recommended where $(NH_4)_2SO_4$ is used.

C. R. F.

The banana. D. W. MAY. Porto Rico Agr. Expt. Sta., *Rept. of the* 1927, 7-8.—Analyses showed that K_2O is present in the banana plant in unusually large amts. The % of K_2O in the dry matter varied considerably in different varieties as follows: Gigante 2.89, Manzano 1.8, Señorita 3.7, Morado 4.02, Chamalaco (cooking variety) 1.83 and Enano 12.17. There was a striking relation between the K_2O content and freedom from disease, Enano being very resistant and Chamalaco very susceptible to diseases. Heavy K_2O applications also produced vigorous plants with desirable sucker growths.

C. R. F.

Respiration of sorghum grains. D. A. COLEMAN, B. E. ROTHGREN and H. C. FELLOWS. Grain Div., Bur. Agr. Economics. U. S. Dept. Agr., *Tech. Bull.* 100, 1-16(1928).—All cereals are similar in that hygroscopic moisture is in equil. at 25-28% with atm. of different relative humidities, the exception being that at above 75% humidity, sorghum grain contained less H_2O . At high moisture contents, cracked and broken sorghum kernels respire more vigorously than do normal whole kernels. Accordingly, an increased risk is involved in storing and transporting sorghum grains that contain appreciable quantities of broken kernels. The chief responsibility for the greater storage difficulties of the sorghum grains, as compared with other cereal grains

is in the high % of cracked kernels usually present in com. lots of sorghum grains. Heat-damaged sorghums likewise respire more vigorously than do sound kernels. Grain which has been exposed to incipient heating develops a condition which makes it unsafe for storage, as it seems to go out of condition more rapidly than does sound grain under the same conditions. Storage tests made under lab. conditions bear out in a general way the findings of the respiration studies, namely, that if the temp. is sufficiently high, 38° or more, sorghum grains that contain over 14% of moisture will go out of condition.

The constituents of corn silk. TARO NOGUCHI. *Bull. Inst. Phys.-Chem. Research (Tokyo)* 8, 143-51 (1929); Abstract Ed., 2, 21-22.- The Et₂O ext. of corn silk gives an alc. C₂₂H₄₀O, m. 74-5°, mol. weight 458-66 in camphor. Its Ac deriv. has been prepd. Phytosterol is found in the alc. ext. of corn silk. Ketoses, aldoses and pentoses are present in the sugar fraction. The basic Pb acetate fraction gives the flavone reaction. Vitamins A and B were proved to exist by animal expts. The presence of vitamin E is doubtful.

ALBERT L. HENNE

Quantitative study of the course of fungal invasion of the apple fruit and its bearing on the nature of disease resistance. I. A statistical method of studying fungal invasion. F. G. GREGORY AND A. S. HORNE. *Proc. Roy. Soc. (London)* B102, 427-43 (1928).—Resistance to invasion is best measured by the rate of radial advance of the disease. II. The application of the statistical method to certain specific problems. A. S. HORNE AND F. G. GREGORY. *Ibid* 444-66.—High resistance to fungal invasion is assocd. with low H₂O content, high acidity, high K content, and low N content.

JOSEPH S. HEPBURN

Damages to vegetation from gases in smoke. KURT NOACK. *Z. angew. Chem.* 42, 123-6 (1929).—Small quantities of SO₂, HCl, NH₃ and H₂S in the gases in contact with plants may have a detrimental effect. The action of these substances in soln. on the soil is another factor to be considered. N. used clover, spinach, tobacco and corn. The poisoning seems to be due to an action on the Fe of the chloroplasts, interfering with its catalytic effects in assimilation. Apparently secondary changes affect the photochem. oxidative processes of the plant so that bleaching and the death of cells result. Since it seems impractical to attempt completely to eliminate these harmful constituents from industrial gases, growers should avoid planting unusually sensitive plants where contamination of the air may occur, and should pay particular heed to the effects of meteorological changes in this connection.

G. ALBERT HILL

Structure and chemical properties of the epidermis of *Clivia nobilis*. DONALD B. ANDERSON. *Jahrb. wiss. Botan.* 69, 501-14 (1928).—The structure and chem. properties of the epidermal layer of *Clivia nobilis* were studied by means of polarized light, staining and other reactions according to the methods of Kisser and Molisch. The epidermis was composed of 3 distinct layers: namely, a cuticle consisting of pure cutin; a cuticular layer composed of cutin, cellulose and pectic materials; and a cellulose layer contg. cellulose and pectic substances. Pectic substances were concd. between the cellulose and cuticular layers. The inner half of the cuticular layer was composed of cellulose and pectic substances which were infiltrated with cutin, the pectic substances decreasing toward the lumen side. The outer half of the cuticular layer consisted of cutin and none or only a trace of pectic substances, the cellulose decreasing and the cutin increasing toward the cuticle side. It is assumed that the increase in double refraction from the lumen toward the middle of the cellulose layer is due to a decrease in H₂O content in the cellulose lamella. These data represent the combined results of 3 different methods for detg. the structure and chem. properties of the epidermis.

A. E. HITCHCOCK

Biochemical characteristics of aging in leaves. A. I. SMIRNOV, P. S. ERIGIN, M. A. DUBOGLAV AND M. TH. MASHKOVZEV. *Planta, Abt. E., Z. wiss. Biol.* 6, 687-764 (1928).—Analyses showed that aging in sunflower and tobacco leaves is accompanied by the following changes: increased dry wt., increased ratio of maltose to sucrose, decreased activity of respiration enzymes, increased total N (except during flowering), an initial increase followed by a decrease in protein synthesis, and the accumulation of amino, amide and ammonia N in the form of org. acids. Nicotine N increased steadily in tobacco leaves. The trend of changes in other forms of N and carbohydrates was essentially the same in both plants, especially just before and after flowering, with the exception of sucrose. Flowering in the sunflower was characterized by a relatively high content of reducing sugars and a relatively low content of maltose, starch, sucrose, lexitrin, total N and protein N. A similar situation existed in the tobacco with the exception of sucrose which remained high. A higher content of total N in the upper compared to the lower leaves is believed to be due to a greater absorption capacity

in the upper leaves. Conclusion: Protein synthesis is dependent mainly upon the supply of carbohydrates during the first stages of growth, but later the amt. of respiration energy becomes an important factor. In the early stages of growth maltose is utilized as fast as it is formed and the accumulation of org. acids in the late stages of growth appears to be due to a decline in the rate of protein synthesis. A. E. H.

Carbohydrate metabolism in evergreen leaves during the year. HERMAN GUTTENBERG. *Planta Abt. E., Z. wiss. Biol.* 6, 801-8(1928).—The following conditions were found in leaves of *Ilex aquifolium* and *Hedera helix* during Oct.-March: total carbohydrates were low (starch and sucrose absent), and glucosides were high in Oct. only. The dry wt. of *Hedera* leaves was low during the entire period, while that of *Ilex* leaves was medium high, decreasing to a min. in March. From Apr. to Aug. *Ilex* and *Hedera* leaves both contained an abundance of starch and sucrose, but were low in glucose except during July. *Ilex* contained the max. amt. of glucosides (8% in old and none in new leaves during June) while *Hedera* contained traces only. The dry wt. of *Ilex* leaves was high during the entire period while that of *Hedera* was low in the spring, increasing to a max. in July. In spite of a low carbohydrate content the dry wt. of *Ilex* leaves continued to increase and remained high until the middle of Nov. For *Hedera* leaves on the contrary, the dry wt. remained low while carbohydrates were accumulating. It appears, therefore, that an increase in dry wt. is dependent upon factors other than the carbohydrate supply. *Pinus cembra*, in contrast to *Ilex* and *Hedera*, contained starch, sucrose and glucose during the entire year. A. E. HITCHCOCK.

The formation of chlorophyll and its relation to the blood pigment. KURT NOCK. Botan. Inst., Erlangen. *Naturwissenschaften* 17, 104(1929).—Protochlorophyll occurring in yellow leaves splits off Mg on acid treatment and allows reintroduction of Mg by Grignard reaction. The Mg-free compd., a red dye, has absorption bands almost identical with those of phyloerythrin (bilipurpurin). Amts. of the latter prepd. from gall of animals yielded, after Mg introduction, a green dye, almost identical to protochlorophyll in the spectrum. The phyloerythrin contains one or more carboxyl groups in lactone or lactam bond. From the Mg-free deriv. of chlorophyll a or c (pheophytins), from their allomers and from phytochlorins the Mg-free protochlorophyll deriv. could be made by reduction in acid soln. in good yield, without ester hydrolysis. Sapon. of the reduction products gives carboxylic acids which as well as their Me esters give the same absorption spectrum as sapond. phyloerythrin. Illumination (photooxidation) transformed these products into green substances. It is thus apparent that simple reduction is a bridge between the coloring matter of leaves and of blood. Chlorophyll formation in the plant is in its final stage a photooxidation; the influence of iron on it is considered catalytic. (C. A. 20, 2521.) B. J. C. VAN DER HOEVEN.

Studies on the role of phosphorus in the life of yeast and in alcoholic fermentation. E. ELION. *Nederland. Tijdschr. Hyg., Microbiol. en Serol.* 3, No. 3, 229-40(1928), cf. C. A. 22, 1174.—The action of P in fermentations produced by zymase or yeast preps. contg. zymase is quant., but neither the yeast production nor the activity of the yeast increased in proportion to the quantity of P added. P does not act quantitatively in fermentations caused by living yeast as, e. g., in fermentation caused by zymase produced from the living yeast cell. Every fermentation is accompanied by the formation of esters of H_3PO_4 . The pancreatic juice of the snail, *Helix pomatia*, retards the P esterification by an active zymine, caused by the presence of a substance of an enzymic nature, which splits up the esters after they are formed, and which is called phosphatase. Efforts to ferment mannitol, dulcitol, arabinose and galactose by active zymine produced neg. results. Conclusion: The non-fermentable sugars and even galactose do not form H_3PO_4 esters, and it seems that the configuration, which plays a role in fermentation, is also of importance in the formation of these esters. J. C. JUKRIENS.

The influence of different physical and chemical agents on the spores of one of the species of *Penicillium*. J. DE GRAAFF. *Nederland. Tijdschr. Hyg., Microbiol. en Serol.* 3, No. 3, 249-53(1928).—The spores of the species of *Penicillium* examined died at 60-65° in an aq. medium, in liquid fat at 80-90°. All spores died when exposed to the rays of a quartz Hg lamp at a distance of 30 cm. for 5 mins. Liquid fats cannot be sterilized by ultra-violet rays, even in thin layers. The spores could not be killed with a very concd. soln. of NaCl. H_2O_2 (0.05%) killed all spores within 1 day. Cloves are the most effective of the species to prevent mold growth. Quinine (0.1-0.5%) and eucupine (0.03-0.1%) prevent the growth of mold. J. C. JUKRIENS.

The assimilation of the molecular nitrogen of the air by lower plants, especially by fungi. G. SARR. *Biol. Reviews Biol. Proc. Cambridge Phil. Soc.* 3, 77-91(1928).—S. states that the ratio of org. to inorg. compds. on the surface of the earth remains

unaltered. The ratio of the mol. N of the air to the compds. of this element is also a const. Combustion and fermentation produce mol. N from its compds. Bacteria and fungi effect the reverse reactions—the fixation of N. Detailed discussion is given of the latter process.

L. B. MILLER

Qualitative and quantitative variations in the nitrogenous substances of a woody plant at the beginning of the vegetative period. M. PINEY. *Rev. gen. botan.* 41, 65-94(1929); cf. *C. A.* 21, 2015.—Beech trees, 3 years old at the beginning of the expt., were sampled every month for 8 months starting with Dec. 26th, and protein and non-protein N detd. Protein N is at a max. in the winter in stems and roots, while its max. in the leaves is at the time of their first appearance. Sol. N is highest before the development of the shoots. It then decreases regularly in all organs to a very low value in summer; the ratio of sol. N to total N varies from $\frac{1}{4}$ to $\frac{1}{11}$ throughout the period studied. In regard to N compds. the trees have a rest period of about 2 months only, physiol. activity starting about 2 months before the opening of the buds.

LAWRENCE P. MILLER

Non-nitrogenous constituents of corn silk. I. Y. TSUKUNAGA. *J. Pharm. Soc. (Japan)* 48, 981-90(1928).—The chief non-nitrogenous constituents of Manchurian corn silk are glucose, pentosan, galactan, phytosterol, etc. Org. acid and mineral substances are also found in small quantity.

F. I. NAKAMURA

The secretion of the aleurone layer and scutellum. J. GRUSS. *Wochschr. Brau.* 45, 497-500, 506-9(1928). Both the scutellum and the aleurone cells secrete diastase and peroxidase. The starch-contg. cells of the endosperm do not have the power of producing these enzymes.

A. SCHULTZ

An iodine liberator from Laminariae. THOMAS DILLON. Univ. Coll., Galway. *Nature* 123, 101-2(1929).—Fresh fronds of *Laminaria digitata* or *L. saccharina* were minced and treated with their own wt. of distd. H_2O contg. 5 cc. toluene per l. After standing for about 24 hrs. the liquid was filtered through a Buchner funnel without filter paper. On treating this liquid with HCl (or AcOH) and KI soln. there occurred liberation of I. The I-liberating principle dialyzes through parchment; it is not affected by boiling. It is of org. nature since its activity disappeared when 25 cc. of the dialyzed soln. was evapd. and the residue heated: a soln. of the heated residue in dil. HCl was inactive. D. thinks this I-liberating principle might enable algae to collect I from sea water, the liberated I combining with unsatd. compds. present in the algae. No liberation of I was observed in expts. with exts. from *Fucus*.

G. SCHWOCH

The percentage of nitrogen in different parts of soy-bean plants at different stages of growth. LEWIS W. ERDMAN. The Nitragin Co., Inc., Milwaukee, Wis. *J. Am. Soc. Agron.* 21, 361-6(1929).—When seed varieties are cut for hay they contain a higher % of N in their nodules than the regular hay varieties. Seed varieties are richer in protein than hay varieties. As the % of N in soy-bean nodules decreases there is a corresponding increase in N in the tops. Thus a translocation of N takes place from the nodules to the seeds of the plants. In the early growth stages there is a gradual decrease in the % of N in soy-bean tops, but during Sept. the % of N begins to increase and usually reaches a max. at maturity. Analyses of soy-bean plant roots that have been stripped of their nodules show very little variation in % of N during the various stages of growth; thus indicating that the translocation of N from the nodules is extremely rapid.

F—PHYSIOLOGY

E. K. MARSHALL, JR.

Basal and resting metabolism after radiation with ultra-violet light. I. The effect of ultra-violet radiation on the resting metabolism of birds. ELIZABETH CROFTS. *Am. J. Hyg.* 8, 1014-9(1928).—In the canary exposure to ultra-violet radiation from the quartz Hg vapor lamp results in an abrupt drop in O consumption, the av. drop being about 14%. With heavy doses this fall is followed by a belated rise of 21% 2-6 days after the radiation. The initial drop lasted longer, and the interval before the rise was greater with extremely heavy doses. II. The effect of ultra-violet radiation on the basal metabolism of human subjects. *Ibid* 1020-3. Both light and heavy doses of ultra-violet radiation failed to affect the basal metabolism of 6 normal human subjects. III. The effect of ultra-violet radiation on the resting metabolism of normal rabbits. MARY HARDY. *Ibid* 1024-9. Ultra-violet radiation has no effect on the resting metabolism of normal rabbits. J. B. BROWN

Normal blood determinations in the South. MAXWELL M. WINTROBE AND MORRIS W. MILLER. *Arch. Internal Med.* 43, 96-113(1929).—Observations on the blood of 100 normal young men showed an av. red cell count of 5,850,000, 15.87 g. hemoglobin per 100 cc., and 46.5 cc. of packed red cells per 100 cc. The red cell count is somewhat higher than the av. elsewhere. J. B. BROWN

The influence of fatigue products upon muscular efficiency. NIKOLAUS KUENZLE, zsgw. Kaiser-Wilhelm-Inst. für Arbeitsphysiol., Berlin. *Arbeitsphysiologie* 1, 205-12 (1928).—The perfusion of a frog's muscle with Ringer's soln., which had passed through the blood vessels of a fatigued muscle, resulted in a lowering of the irritability, a rise of the threshold stimulus, a decrease in the height of contraction, a lowering of the stimulus frequency by which the muscle went into tetanus, a decrease of the work accomplished, and a shortening of duration of the capacity to react. When the perfusion liquid was satd. with O, its toxic action was considerably decreased. T. M. C.

Amount of blood, red corpuscles and hemoglobin in persons acclimated at sea level and at high level. R. MARGARIA AND E. SAREGNO. *Atti accad. Lincei* 8, 101-7 (1928).—Expts. on 12 persons show that when acclimated to high levels there is an av. increase of 12% in red corpuscles, 5% hemoglobin and 1.8% mass of blood. A. W. CANTERI

The mechanism of secretion of calcium and phosphorus in milk. NORMAN C. WRIGHT. Natl. Inst. for Research in Dairying, Univ. of Reading. *J. Agr. Sci.* 18, 478-85(1928).—The formation of colloidal CaHPO_4 by interaction of CaCl_2 and Na_2HPO_4 in the presence of neutral caseinates is demonstrated. The colloidal CaHPO_4 is shown to be non-diffusible across a cellophane membrane. A theory is formulated to account for the secretion of high concns. of Ca and P in milk from the low concns. of these elements in the blood. Two general mechanisms may be involved: (1) the action of the casein, synthesized in the milk cells of the mammary gland from the freely diffusible amino acids of the blood and capable of causing a selective absorption

of Ca by formation of the slightly dissociated Ca caseinate; (2) the process of supersatn. of this caseinate soln. with CaHPO_4 , leading to the formation of a colloidal and non-diffusible soln. of this salt which is trapped in the milk cells. P. R. DAWSON

Importance of hormones. HUBERT MACHON. *Apoth.-Ztg.* 44, 276-80(1929).—A discussion of the most important glandular exts., their physical characters and action.

W. O. E.

Physiology of the ruminant stomach (bovine). Study of the dynamic factors. A. F. SCHALK AND R. S. AMADON. N. Dak. Agr. Expt. Sta. Fargo, *Bull.* 216, 1-64 (1928).—An exhaustive physiol. study.

C. R. F.

The presence of glycogen in the kidney of the new-born and in non-diabetic individuals. The question of the so-called glycogen-free organs. STAM. DIAMANTOPOULOS. Univ. Bern. *Klin. Wochschr.* 7, 1962-3(1928).—This is a preliminary report. The detailed report is to appear elsewhere. Glycogen has been found in the kidney of 3 out of 10 cases studied (new born). Glycogen has also been found in the pancreas, fatty tissue, thymus, testicle and hypophysis. The kidneys of children and of adults occasionally contain glycogen.

MILTON HANKE

Changes in the water content of blood after the peroral administration of water. B. BRAHN AND P. BIELSCHOWSKY. *Klin. Wochschr.* 7, 2004-6(1928).—The peroral administration of water to rabbits (66% of the calcd. total blood vol. of the animal) leads to a slight (2%) diln. of the blood, an initial fall (5%) in plasma N and a subsequent greater fall (7%) in corpuscle N.

MILTON HANKE

Purine metabolism of muscle and the mother substance of the ammonia that occurs in muscle. II. J. K. PARNAS. *Klin. Wochschr.* 7, 2011-2(1928); cf. C. A. 22, 4600-1.—Adenine occurs in muscle only in the form of nucleotide. In June, the muscles of frogs contain 170 mg. % adenine nucleotide and 20% inosinic acid. Macerated muscle contains only 39 mg. % adenine nucleotide and 130 mg. % inosinic acid. A muscle that is forced by nerve stimulation to contract to the point of fatigue gives off an amt. of NH_3 that is exactly equal to the amt. of adenine nucleotide that is converted into inosinic acid. A muscle that contracts occasionally under conditions such that it does not become fatigued liberates more NH_3 than can be accounted for on the basis of the above transformation. Hypoxanthine nucleotide is transformed back into adenine nucleotide at the expense of the N contained in amino acids if sufficient time elapses between muscle contractions.

MILTON HANKE

The ability of the erythrocytes to take up levulose. G. EISNER AND F. LEWY. *Klin. Wochschr.* 7, 2111(1928). Erythrocytes remove glucose, *in vitro*, from the liquid in which they are suspended. The addition of insulin to this liquid does not, uniformly, have any effect upon the process. Levulose is not utilized by erythrocytes *in vitro* either in the absence or in the presence of insulin.

MILTON HANKE

Mechanism of secretion in the thyroid gland. I. The normal gland in prolonged functional activity. R. J. LUDFORD. Imp. Cancer Research Fund, London. *Proc. Roy. Soc. (London)* B104, 24-32(1928).—In the normal thyroid gland, even during prolonged increased functional activity, the cells discharge their secretion into the lumen of a vesicle which delivers it to the blood stream. Direct secretion into the capillaries does not occur. II. The gland in exophthalmic goiter. *Ibid* 32-9. In exophthalmic goiter in the mouse and man, the mitochondria and the Golgi app. become considerably enlarged, a condition characteristic of intense secretory activity. Frequently the polarity of the Golgi app. is reversed. In the mouse, the secretion droplets, formed in assocn. with the reversed app., are discharged directly into the blood capillaries.

JOSEPH S. HEPBURN

Respiratory quotient of the excess metabolism of exercise. C. H. BEST, K. FURUSAWA, AND J. H. RIDORT. Toronto, Cornell and London Univs. *Proc. Roy. Soc. (London)* B104, 119-51 (1929).—The respiratory quotient of the excess metabolism of muscular exercise is not invariably unity, but increases with the severity of the exercise from a value approx. the same as the basal quotient for very mild exercise, through unity for moderate exercise, to one considerably above unity for very severe exertion. If one disregards the excess metabolism and calcs. the quotient of the total metabolism of exercise and recovery, a similar rise with increasing intensity of exercise, from values characteristic of the resting state to quotients in excess of unity, is obtained.

JOSEPH S. HEPBURN

Free energy of glycogen-lactic acid breakdown in muscle. DEAN BURK. Univ. London. *Proc. Roy. Soc. (London)* B104, 153-70(1929).—The free energy of anaerobic glycogen-lactic acid breakdown in muscle is 1.5 to 2 times as great as the corresponding heat of reaction. In the aerobic breakdown, the free energy is only 1 to 6% greater than the heat of reaction.

JOSEPH S. HEPBURN

Functions of the corpus luteum. III. Factors concerned in the development of the mammary gland. A. S. PARKES. Univ. London. *Proc. Roy. Soc. (London)* B104, 180-97(1929).—Complete development of the mammary gland is due solely to prolonged endocrine action of the corpus luteum; no fetal factor is involved.

JOSEPH S. HEPBURN

Metabolic peculiarities of the growing organism. TH. BREHME, P. GYÖRGY AND W. KELLER. *Jahrb. Kinderheilk.* 120, 42-7(1928).—The anaerobic glycolysis of animal tissues was detd. by measuring in a manometer the gas evolved on incubation in Ringer-glucose soln. under an atm. of $N-CO_2$. The glycolytic activity of the kidney of the newborn rat is about 52% higher than that of the full-grown rat.

E. M. H.

The daily fluctuations of the carbon dioxide pressure the alveolar air. W. RADSMA AND MOEHAMAD JOENORS. *Geneeskund. Tijdschr. Ned.-Indië* 68, 781-801(1928).—Concerning the daily fluctuations, especially in the rise in pressure in the afternoon, there are individual differences. With subjects this increase takes place without exception, with others only occasionally, and with one subject it was not observed with certainty in 7 measurements. During the eclipse of Jan. 1926, an increase of alveolar CO_2 pressure was observed in 2 subjects. It is not clear yet what is the exterior cause of the fall and rise in pressure during the tropical day, especially not the typical sudden afternoon rise. The fluctuations do not go hand in hand with those of the intensity of metabolism; on the contrary, with a decrease of the latter in the afternoon hours, the alveolar pressure increases. A decreased lung ventilation causes the rise of the CO_2 pressure. Measurements of basal metabolism were made with 5 subjects, and the results were all lower than the standard nos. according to Benedict.

J. C. JURRIJNS

The alveolar carbon dioxide pressure of inhabitants of the tropics compared with those of Europe. W. RADSMA. *Geneeskund. Tijdschr. Nederland.-Indië* 68, 812-19(1928).—The typical fluctuations of the alveolar CO_2 pressure of one subject in the tropics were not observed in the same subject in Groningen, Holland. In 3 subjects the pressure in Groningen was considerable higher than in Batavia. In 35 male subjects in the tropics the av. alveolar CO_2 pressure was 36.7 mm., with a probable error of 0.41 mm.; the max. was 43.84 mm., the min. 28.52 mm. In 59 male subjects in Europe, the av. was 39 mm. with a probable error of 0.23 mm.; the max. was 46.91 and the min. 32.8 mm.

J. C. JURRIJNS

The absorption, deposition and transport of fat in the guinea pig. J. LOREAN SMITH AND THEODORE RETTIE. Univ. of Edinburgh. *Quart. J. Exptl. Physiol.* 19, 51-60(1928).—In the intestine a proportion of the fat absorbed from the food is deposited in the villi in the form of large immobile masses. Extracellular deposition of fat in lymphatic channels and perhaps tissue-spaces is peculiar to the guinea pig. In all other animals investigated deposition in tissues occurs in cells only. Reduction of fat in the diet to a trace (0.1%) is followed in a few days by complete reabsorption of this deposit. When a fat-contg. diet (4%) is restored, the deposits reappear in 2 to 3 days.

FRANCIS KRASNOW

The chemical physiology of the placenta with special reference to the occurrence of choline. II. H. SIEVERS. *Physiol. Inst. Marburg. Z. Biol.* 88, 145-52(1928). Fresh placenta was boiled with water and the ext. concd. An alc. ext. of the concentrate was satd. with sublimate, the ppt. sep'd. and decomposed with H_2SO_4 . The choline thus obtained was concd. and pptd. with $AuCl_3$, giving cholineaurate. The quantities found in normal placenta differed from those obtained for placenta of eclamptic cases, 0.10 to 0.12 g. in the former and 0.13 to 20 g. in the latter.

Metabolism in the athlete. O. FLÖSOMER AND F. KUTSCHER. Univ. Marburg. *Z. Biol.* 88, 382-9(1929). Hippuric acid, lactic acid, adenine, methylguanidine, phenylalanine, γ -butyrobetaine and choline were found in the urine.

Total sugar of blood and urine. II. The hydrolyzable sugar of blood. MARK R. EVERETT AND FAY SHEPPARD. Univ. of Okla. Med. School. *J. Biol. Chem.* 80, 255-68(1928); cf. *C. A.*, 21, 3919.—Evidence is presented to show that the hydrolyzable sugar of blood actually exists and is not due to analytical errors. Normal human plasma contains from 1.5 to 5 mg. (av. 3) of hydrolyzable sugar per 100 cc. (detd. by the Folin-Wu procedure) and whole blood 6 to 16 mg. (av. 10). The effects of fermentation and of alkali hydrolysis upon the hydrolyzable sugar indicate that it resembles glycogen but the latter has never been found in sufficient quantities in normal blood to account for more than a small part of the hydrolyzable sugar. A sample of leucemic blood contained more hydrolyzable sugar but not enough to indicate that the white cells are the chief source of this material. Essentials for the analysis of dil. sugar solns. are discussed.

A. P. LOTHROP

The concentration of acid and base in the serum in normal pregnancy. HARRY C. OARD AND JOHN P. PETERS. Yale Univ. and New Haven Hosp. *J. Biol. Chem.* 81, 9-27(1929).—The direct method of Peters, Bulger, Eisenman and Lee (*C. A.* 20, 1101) for detg. the total acid-base equil. of serum was used in the examn. of the sera of normal pregnant individuals. Inorg. P and chlorides show no change from the normal. There is a reduction of about 5% (8 milli-equivs. per l.) of total base, this being almost entirely at the expense of the Na. Accompanying this change in total base there is an equal reduction of the anion content, chiefly serum bicarbonate and org. acid but also to a lesser extent serum protein. The reduction of reserve alkali in the "acidosis of pregnancy" is assocd. with a diminution of base so that this term as connoting an actual collection of abnormal acids in the blood is misleading. The pregnant organism has a unique ability to tolerate a reduced concn. of serum electrolytes but there is no satisfactory explanation for the changes which occur. A. P. L.

The relations of the serum proteins and lipids to the osmotic pressure. ELLA H. FISHBERG. Beth Israel Hosp., N. Y. *J. Biol. Chem.* 81, 205-14(1929).—"The relationship between the concn. of proteins and the osmotic pressure of blood sera is expressed by the equation $p = \frac{c}{a}$, where p is the reciprocal of the osmotic pressure, c the reciprocal of the protein concn., and a a const. dependent on the particular serum; that is, that when the proteins decrease in arithmetical progression, the osmotic pressure decreases in geometric progression. The lipemia that follows intensive hemorrhage in rabbits may perhaps be correlated with an effort of the organism to compensate for the decrease in osmotic pressure following the loss of serum proteins. The osmotic pressure per g. of protein is higher in lipemic blood than in blood dild. to the same concn. of protein, and this difference becomes apparent at the same time that the total lipid content of the blood starts to rise." A. P. LOTHROP

Adrenal insufficiency. VI. The influence of "heat" on the survival period of dogs after adrenalectomy. J. M. ROGOFF AND G. N. STEWART. Western Reserve Univ. *Am. J. Physiol.* 86, 20-2(1928); cf. *C. A.* 22, 273.—When the adrenals were removed from bitches during heat the period of subsequent survival was markedly longer than in control dogs. Conclusion: The changes associated with heat compensate in some way for the adrenals. VII. Further blood studies (cholesterol and calcium) in control adrenalectomized dogs. *Ibid* 23-31.—After the removal of the adrenals in male dogs blood serum Ca was generally increased. This was not due to a concn. of the serum because its sp. gr. and cond. remained unaltered after the operation. The whole blood, however, had a much higher sp. gr. and lower cond. after adrenalectomy. The cholesterol content of the blood did not show any variations as a result of the removal of the adrenals that would offer support to the theory that these glands are concerned with cholesterol metabolism. J. F. LYMAN

Variations of the water content of the blood induced by atmospheric temperature changes in normal and splenectomized animals. F. T. ROGERS AND R. W. LACKEY. Baylor Univ. College Med. *Am. J. Physiol.* 86, 36-8(1928).—Exposure of cats to warm atm. (45 to 50°) for 15 to 30 mins. was followed by diln., and exposure to cold for 20 mins. was followed by a concn. of the blood. The same changes of similar magnitude were observed in splenectomized cats. J. F. LYMAN

Normal menstruation and gaseous metabolism. FRANCIS G. BENEDICT AND MARY D. FINN. Carnegie Inst., Washington. *Am. J. Physiol.* 86, 59-69(1928).—Intermittent measurements on one subject extending over 12 years and almost daily measurements extending over 2 months with the same subject show that O₂ consumption was lowest and most uniform during the menstrual period, and highest about one week after menstruation ceased. J. F. LYMAN

The spleen. II. Changes in hemoglobin following removal of the spleen. G. B. RAY. Western Reserve Univ. *Am. J. Physiol.* 86, 138-44(1928); cf. *C. A.* 23, 1168.—Detns. of total blood pigment, hemoglobin and O₂ capacity of the blood before and after the removal of the spleen in dogs showed that large amts. of non-functional pigment were present in the blood after the operation. This increase was not related to a decrease in the number of red blood cells nor to the total hemoglobin. J. F. LYMAN

Regulation of respiration. XIX. Central and peripheral action of sodium cyanide on respiratory movements. ROBERT GESELL. Univ. Michigan. *Am. J. Physiol.* 86, 164-70(1928).—Injections of NaCN via arteries and via veins by the isolated-head method (*C. A.* 20, 2444) showed that NaCN is absorbed readily by muscle and by nerve tissue. The action of NaCN on the lower nerve centers tended to excite respiration while its action on the head region, excluding the lower nerve centers, was unaccompanied by excitation. J. F. LYMAN

The diuretic-antidiuretic effect of the pressor principle of the posterior lobe of the

pituitary gland. E. P. BUGGER AND A. E. SIMOND. Parke, Davis and Co., Detroit. *Am. J. Physiol.* 86, 171-7(1928).—The pressor principle of the pituitary has a diuretic-antidiuretic effect on green-fed rabbits. The excretion of phenolsulfonephthalein was definitely depressed after administering the hormone. J. F. LYMAN

The inorganic phosphorus of blood and muscle. LAURENCE IRVING AND G. M. BASTEDO. Univ. Toronto. *Am. J. Physiol.* 86, 225-37(1928).—As lactic acid was produced in fatigued muscle, phosphocreatine decomposed, with consequent increase of inorg. phosphate. Under extreme fatigue conditions lactacidogen probably yields some inorg. phosphate. During moderate contractions phosphocreatine may decrease while lactacidogen increases. The inorg. P of the muscle did not appreciably influence the inorganic phosphorus concn. of the blood. J. F. LYMAN

Neural and hormonal factors in bodily activity. The prepotency of medulliadrenal influence in emotional hyperglucemia. S. W. BRITTON. Johns Hopkins Univ. *Am. J. Physiol.* 86, 340-52(1928).—Blood sugar in normal cats excited by dogs rose from 30 to 100% after 2 to 4 mins. excitement. Cutting the splanchnic branches to the liver had but little effect on the excitement blood sugar level. In animals whose adrenal medulla had been destroyed excitement was usually followed by a fall in blood sugar even though liver glycogen was within normal limits. Conclusion: The influence of the adrenals in the liberation of glycogen stores under conditions of urgency is preëminent. J. F. LYMAN

Observations upon adrenalectomized cats treated with the cortical hormone. F. A. HARTMAN, F. R. GRIFFITH, JR., AND W. E. HARTMAN. Univ. Buffalo. *Am. J. Physiol.* 86, 360-70(1928).—Symptoms of chronic adrenal insufficiency were produced in cats by operative removal of the adrenals and semi-daily injections of exts. of adrenal cortex. The survival period extended up to 300 days. The following symptoms were noted: metabolism usually fell after 7 to 20 days; there was no gain of wt., but usually a loss long before the onset of terminal symptoms. Blood urea was often abnormally high, especially so after overeating protein food. There was a high susceptibility to infections, a tendency to subnormal temps. and rapid fatigue on exercising. Removal of the thyroids or the gonads did not modify the survival period. J. F. LYMAN

Aglomerular and glomerular kidneys. II. Physiological. J. GRAHAM EDWARDS AND LUIGI CONDORELLI. Univ. Buffalo and Royal Univ. Naples. *Am. J. Physiol.* 86, 383-98(1928).—The excretion of dyes through the kidneys of various fish was studied and a comparison of the concn. of compds. in the blood and urine of fish, frog, fowl and man was made. The results indicate a role for the tubule not precisely accounted for by the filtration-reabsorption hypothesis. J. F. LYMAN

The presence of melanophore-expanding and uterus-stimulating substance in the pituitary body of early pig embryos. F. F. SNYDER. Univ. of Rochester. *Am. J. Anat.* 41, 399-409(1928).—Melanophore-expanding and uterus-stimulating substances are found in the pituitary of pig embryos of 30 mm. Crown-rump length, i. e., when the fetus is about $\frac{1}{4}$ its length at birth and when the weight of a single gland is about 0.05 mg. C. M. M.

Further experiments with an ovarian hormone in the ovariectomized adult monkey, *Macacus rhesus*, especially the degenerative phase of the experimental menstrual cycle. EDGAR ALLEN. Univ. of Missouri. *Am. J. Anat.* 42, 467-86(1928).—Five hormone exts. were prepd. Two of these were olive oil exts. of human placenta, which were combined with aq. exts. and in one case with liquor folliculi for injection. Attempts were made to substitute injections of these ovarian hormones for the endocrine functions of the ovaries of monkeys. Injections of each of the 5 exts. were made into ovariectomized monkeys over a period of 24 days. All injections yielded the sex characteristics of swelling and reddening of the "sexual skin." Some growth was produced in the mammary glands and genital tract. C. M. M.

Variations in the iodine number of fats in the liver during aseptic autolysis. UGO LOMBEROSO AND ANGELA DI FRISCO. *Boll. soc. ital. biol. sper.* 2, 320-30(1928). *C. A.* 22, 2801.—The I no. of the fatty acids extd. from liver pulp was compared to the fatty acid content of the tissue during aseptic autolysis. The scope of these exts. was to show if, during the process of lipo-diuresis which is accompanied by a more or less complete disappearance of fatty acids, the reduction is at the expense of the unsatd. fatty acids or whether all the fatty acids are involved; also, whether the relation between satd. and unsatd. fatty acids after autolysis was different from that before autolysis. The results of the expts. are summarized as follows: The I no. in those cases in which it was very high in normal samples showed in a few titrations a reduction of almost 50% of the original value. There is a parallelism between the reappearance of the fatty acid and the increase of the I no. but the latter does not reach its original

value. In cases where the I no. is low at the start, it may become still lower at first and later increase so as to reach values higher than the initial ones. As a whole the I no. of the fatty acids in liver during autolysis tends to be a const. regardless of its initial value, when the reformation of the fatty acids takes place. A study of the relation between the percentage diminution of the fatty acids and the reduction of the I no. shows that the latter is in some cases too high; this variation cannot be ascribed to the disappearance of the fatty acids but is due either to the satn. of the unsatd. acids or to some form of oxidation which blocks the reaction with I. PETER MASUCCI

Certain observations on the behavior of phosphagen in the muscle juice. G. MARTINO. *Boll. soc. ital. biol. sper.* 3, 824-6(1928); cf. *C. A.* 23, 406.—Muscle juice with and without addition of creatine and CaCl_2 was allowed to stand 2-24 hrs. at a temp. of 38° , $17-19^\circ$ and $10-12^\circ$. Creatine was added in the proportion of 0.01 g. per 5 cc. of juice. The phosphoric acid and phosphagen contents were detd. in each case. The results showed (1) the addition of creatine to muscle juice and kept at $17-19^\circ$ for 2 hrs. caused a distinct and const. increase of phosphagen and a corresponding decrease in inorg. phosphoric acid. However, detns. up to 24 hrs. after the addn. of creatine did not show any further increase. (2) At a temp. of $10-12^\circ$ there was also an increase of phosphagen but it was less marked than at $17-19^\circ$. (3) At 38° the phosphagen content did not show any difference compared with the creatine-free juice. (4) The addn. of CaCl_2 did not have any effect on the phosphagen content. PETER MASUCCI

The endocellular formation of fat. FRANCESCO CAPELLA. *Boll. soc. ital. biol. sper.* 3, 860-1(1928).—The purpose of these expts. was to det. from what source the fat is derived in fatty degeneration processes. The animal was bled to death, a glass cannula inserted in the portal vein, and artificial circulation was applied to the liver. In the control liver under investigation, circulation was maintained by means of Locke's soln. satd. with phosphine. The organs were then removed and examd. histologically and chemically. There was an increase of fat of 1-3% based on the wt. of the whole organ. The histological findings confirmed these results. C. concludes that the increase in the fatty content of the liver is due to substances which enter directly into the compn. of the hepatic cells. PETER MASUCCI

The occurrence and transformation of pyrophosphate in cells. III. Physiological behavior of pyrophosphate. K. LOHMANN. Kaiser Wilhelm-Inst. für Biologie, Berlin-Dahlem. *Biochem. Z.* 203, 172-207(1928).—Under physiol. conditions the pyrophosphate content of intact frog muscle remains unchanged. A sojourn of 20 hrs. in O_2 and mild stimulation cause no splitting of pyrophosphate, but under longer stimulation there is increasing splitting of pyrophosphate with formation of orthophosphate. In chloroform rigor the source of phosphate is exclusively the pyrophosphate while in heat rigor this is the predominant source. The pyrophosphate does not dialyze from the muscle into Ringer soln. In autolyzing frog muscle pulp or ext. in a NaHCO_3 -KCl soln. at 40° the pyrophosphate is completely hydrolyzed. About 75% of the increased phosphate in autolysis for 1-2 hrs. comes from decompd. pyrophosphate, the remaining 25% (for 0.2-0.3 mg P_2O_5 per g. muscle) come partly from the decompn. of Embden's ester. The enzymic hydrolysis of pyrophosphate is greatly depressed by orthophosphate. Respiration and the hydrolyses of carbohydrate by the cells are independent of the pyrophosphate fraction. The pyrophosphate is probably present in the muscle cell or in the fresh muscle ext. as a protein adsorption compd. Fluoride in large concn. (0.2 M KF) stimulates the hydrolysis of preformed pyrophosphate in fresh frog muscle exts.; intermediate concns. (0.1 M) inhibit this while very small concns. (M/100-M/333) again stimulate it; fluoride inhibits the hydrolysis of added pyrophosphate. Pyrophosphate administered by mouth is hydrolyzed to orthophosphate and is excreted as such through the urine. S. MORGULIS

The occurrence of β -stearodipalmitin in beef thymus. JUNJI KARASHIMA. *Physiol.-chem. Inst., Nagasaki. J. Biochem. (Japan)* 10, 183-7(1928).—Air-dried powdered thymus is extd. 24 hrs. with acetone, and the residue is washed several times with acetone on the filter. The residue freed from acetone is extd. with ether, and on cooling to 0° a substance crystallizes. The sepd. crystals are dissolved in 85% alc. at $45-50^\circ$; they reappear at room temp. They are once more recrystd. from warm abs. alc. The substance is easily sol. in ether, benzene, toluene, pyridine, CS_2 , and CHCl_3 , and somewhat sol. in AcOEt . It is almost insol. in cold acetone, ethyl, methyl or amyl alc.; it m. 50° . From its elementary compn. and other detns. it has been identified as β -stearodipalmitin. The thymus involution coincident to age is always accompanied by an increase in the β -stearodipalmitin fraction (7.4 to 25.7% of total fat with increasing age). S. MORGULIS

Influence of removal of the hemispheres on temperature, gaseous metabolism

and weight in pigeons. N. POPOV AND B. BAYANDUROV. *Zhurnal ekspl. Biol. Med.* 10, 235-45(1928).—Decerebrate pigeons gain even up to $\frac{1}{2}$ of their initial wt. on a diet which does not differ from that before the operation. The CO_2 production following decerebration, even when there is increased muscular activity, is generally diminished, though only for a short period. The increase in wt. frequently is accompanied by a rise in metabolism and temp.

S. MORGULIS

Experiments on the motility of the crop in thyroidectomized birds. A. S. LIEBERFARB. Sverdlov Communist Univ., Moscow. *Zhurnal ekspl. Biol. Med.* 10, 332-9 (1928); cf. C. A. 22, 1400.—Feeding dry thyroid or injection of thyroxine causes increased activity of the crop in chickens. Thyroidectomy causes inhibition of the crop motility, which even a year after the operation remains subnormal. On the contrary, the administration of thyroxine or feeding the dry thyroid powder produces an immediate return to normal behavior. The effect of satiety or of prolonged starvation on the motility of the crop. *Ibid* 341-8(1928).—Satiety generally leads to cessation of the movements of the crop. Both hunger and thirst may cause motility, and in case of thirst feeding instead of diminishing the movement may actually induce greater motility. With the prolongation of the starvation there is increased tonicity though the number and amplitude of the contractions are increased only when the fast is not of excessive duration.

S. MORGULIS

The effect of secretin in the regulation of the alkali reserve of the blood. I. The influence of secretin in experimental alkalosis. A. O. WOINAR. Inst. of Med. Odessa. *Zhurnal ekspl. Biol. Med.* 10, 414-22(1928).—Secretin plays an important part in the regulation of the alk. reserve. A direct dependence is observed between the variations in alky. and amt. of secretin in the pancreatic juice and the alky. of the blood. Under conditions inducing a drop in the alk. reserve of the blood there is likewise a diminution in the alky. of the secreted pancreatic juice. Raising the alk. reserve artificially causes an increase in the alky. of the secretion.

S. MORGULIS

Studies concerning the value of a solution of glucose in maintaining the acid-base equilibrium of the blood in pregnant animals. II. The effect of a period of chloroform anesthesia in pregnant animals. The lack of protection conferred by a solution of glucose. WM. DEB. MACNIDER. Univ. of North Carolina. *J. Pharmacol* 35, 31-48 (1929); cf. C. A. 21, 264.—Feeding glucose to pregnant dogs does not prevent the decrease in alkali reserve, in elimination of phenolsulfonephthalein, or in urine formation after CHCl_3 anesthesia. These disturbances after CHCl_3 are more marked in older animals far advanced in the gestation period than in younger animals early in the period of gestation.

C. RIDGE

Artificial blood circulation of the total organism with excluded heart. S. S. DRYKOWENKO. *Trans. Sci. Chem. Pharm. Inst. (Moscow)* 1928, No 20, 44-72. On several occasions the heart of an exptl. dog, after it had gone into fibrillations or had completely stopped, resumed its normal action when 0.5 cc. of a 1:1000 soln. of adrenaline was added to the perfusion fluid.

P. W. SALT

Combined sugar. A. GREVENSTUK. *Arch. niderland. physiol.* 12, 265-72(1929). The total amt. of sugar in the blood was detd. by hydrolyzing the blood with H_2SO_4 , pptg. the proteins with HgNO_3 , and then analyzing the filtrate for total sugar by the Folin-Wu method. The free sugar was detd. by the usual procedure. This value was then subtracted from the total amt. and gave the combined sugar. Rabbits received a subcutaneous injection of a unit of insulin; the total blood sugar fell but rapidly returned to normal. The combined sugar increased slightly in animals starved for 24 hrs. and sometimes in well-fed ones. It was, therefore, a product of metabolism and its absolute value was greater than that of the free sugar. Portions of the liver of rabbits were removed through an abdominal window. The free and total sugar and the glycogen were detd. in each sample of liver removed as well as the blood sugar. After 4 days' starvation the glycogen was usually less than 0.22%, and the combined sugar more than 0.55%. In 3 of the 16 animals and in 2 of these the combined sugar was low, suggesting an inverse relationship between the two. Over a period of 4 hrs. both varied in the same or different directions in the same or different animals; 0.05 to 5 units of insulin produced no variations different from those seen in the controls.

M. H. SALT

The secretion of hydrochloric acid into the stomach. J. R. F. RASSERS. Leyden. *Arch. niderland. physiol.* 12, 514-20(1928).—A "leicithalumin" was obtained from the mucosa of hog stomach. This substance was added in 0.5-g. quantities to 20 cc. of an 0.9% soln. of NaCl . The mixts. were incubated at 37° for 30 mins. and then treated with 0.01 N NaOH with phenolphthalein as indicator. Free HCl was present in the soln. Conclusion: The leicithalumin of the stomach mucosa is capable of de-

composing NaCl soles.; the Na^+ is adsorbed and free HCl is secreted into the stomach.

M. H. SOULE

Biometry of calcium, inorganic phosphorus, cholesterol and lipid phosphorus in the blood of rabbits. II. Repeated observations on normal animals. ALVIN R. HARNES. Rockefeller Inst. Medical Research. *J. Exptl. Med.* 49, 287-301(1929); cf. *C. A.* 22, 4161.—A series of detns. of inorg. P, Ca, cholesterol and lecithin was made on a group of 10 animals living in the lab. from Oct. 27, 1927 to May 17, 1928. A marked difference in both the trend and abs. values was noted in animals living in the lab. when compared with the values obtained for animals living out-of-doors. With animals living in the open, the trend of variation for Ca was found to be the same. However, animals living in the lab. maintained a higher level over the same period of time. The inorg. P and lecithin both showed a marked decrease and both maintained a lower level than was found in animals just received from the dealer. The cholesterol content of whole blood exhibited a similar trend in both groups of animals. However, it was found that animals living in the lab. maintained a lower level than animals living out-of-doors. The mean value for Ca was found to be 15.7 ± 0.05 , for inorg. P 4.65 ± 0.05 mg. per 100 cc. of blood serum, and for cholesterol 58.2 ± 0.39 and lecithin 118.4 ± 1.13 mg. per 100 cc. of whole blood. The coeffs. of correlation having the highest degree of mathematical significance were obtained from the mean values for individual animals.

C. J. WEST

The influence of the pancreas on the metabolism of creatine. A. CORBIA. Univ. Sassari. *Clin. pediatr.* 10, 195-212(1928); *Ber. ges. Physiol. exptl. Pharmacol.* 46, 393.—C. studied the changes in the creatine metabolism while the pancreas is partly or totally excluded. Dogs and cats were used as the subjects, since these animals normally show a slight amt. of creatine in the urine. The creatine in the urine was detd. by the Folin-Benedict method, that in the blood by the Folin-Doisy method with the Dubosecq colorimeter. The complete removal of the pancreas or its equiv. provokes at first a noteworthy increase in the elimination of creatine substances, particularly of creatine, while later the increase is less and just before death all values sink. The temporary exclusion of the pancreas produces the same increase but the total amt. of creatine is less definite and less const.; furthermore, the disparity between creatine and creatinine is less. As far as could be observed there is no change in the blood. The changes which were observed are not to be ascribed only to the suppressed endocrine function, but also and in a high degree to the increased external secretion through which the almost entirely suppressed resorption of fats, carbohydrates and protein and the subsequent use of the org. reserve is to be ascribed. When insulin is given to animals with or without pancreas, there is a decrease in the elimination of creatinine and especially a decrease in that of creatine.

R. C. WILLSON

Combined sugar and its ratio to total nitrogen in the normal Japanese. KUNITARO KITAMURA. *Med. Acad., Kyoto Kyoto-Ikadasigaku-Zasshi* 2, 241-6(1928); *Ber. ges. Physiol. exptl. Pharmacol.* 45, 85. The subjects were 25 normal Japanese who were studied with the Iizuka method. The amt. of combined sugar ranged from 0.067 to 0.107%, av. 0.091%. Generally the total N increased in proportion to the rise

in combined sugar. $\frac{\text{Total N}}{\text{combined sugar}}$ varied between 9.15 and 10.70, av. 10.10.

$\frac{\text{Free sugar}}{\text{combined sugar}}$ ranged from 0.83 to 1.37, av. 1.15. $\frac{\text{Combined sugar}}{\text{total sugar}}$ ranged from

0.420 to 0.545, av. 0.485. $\frac{\text{Free sugar}}{\text{total sugar}}$ ranged from 0.455 to 0.578, av. 0.518. The high

combined sugar value is assumed to be related to the diet of the Japanese.

R. C. WILLSON

Kidney filter and glucemia. L. PERELMAN. *Med Biol. Zhurnal* 3, 79-90(1927); *Ber. ges. Physiol. exptl. Pharmacol.* 44, 801.—The influence of the elimination of the kidney filter on the sugar was studied after operations of various types, as bilateral nephrectomy, ligation of the renal vessels. Blood sugar was detd. by the Hagedorn-Jensen method. After any of these operations had been performed on normal cats and dogs there was only a very insignificant rise in the blood sugar. In the hyperglucemia of diabetes, however, the blood sugar is increased 1.5 to 2.5 times. During phlorizin glucosuria, after the operation, there is a slight hypoglycemia. Phlorizin injections in uremic animals had either no effect on the blood sugar or caused only a very slight rise in it.

R. C. WILLSON

The influence of liver extirpation on the organism. M. DENISENKO. *Med. Biol. Zhurnal* 2, 22-23(1927); *Ber. ges. Physiol. exptl. Pharmacol.* 44, 801.

eg.) than the saline control. ———. Injections of 1 cc. of 1% lecithin soln. shortened the life of the animals about 30%. Daily NaCl injection lengthened the life of the subjects 50-60%. The hemolyzed blood of the animals on the 6-7th day after the operation exerted an inhibiting effect on the isolated heart of a normal frog.

R. C. WILLSON

The acidity of the gastric juice and of the urine in their connection with each other and with the acid-base equilibrium of the human body. HANS SCHULTEN. Univ. Hamburg. *Münch. med. Wochschr.* 75, 898-901(1928).—In 50 non-febrile subjects without any kidney maladies the whole day- p_H curve was detd. by means of urine tests made hourly or more frequently. The subjects were kept quiet in bed and the diet was a neutral one as far as possible. In subjects with normal gastric acidity (detd. 25 mins. after the ingestion of 200 cc. 5% alcohol), the night urine is usually acid (p_H about 6.0) but alk. was shown before or during breakfast (8.00 a. m.). The peak of the alk. (p_H about 8.0) is often reached after 2-3 hrs. and after temporary and repeated sinking of the p_H to the fasting value. After a reduction, the noon meal effects an increase which is not larger than that following the much smaller breakfast; this is not parallel to the detd. gastric acidity. The appearance of the curve varies considerably. In anacidity (especially in pernicious anemia) the fluctuations are small, rarely exceeding the limits of error. In some cases of achylia the curve is similar to that of normal acidity. An acid peak in the acidity curve was never observed after mealtime. The p_H curve of the urine certainly has something to do with the secretion of gastric juice. Alkaline peaks in the curve are absent after the evening meal.

R. C. WILLSON

Comparative study of the function of both kidneys in bitches. YOSHISUKE YOSHIDA. Univ. Okayama. *Okayama-Igakkaï-Zasshi*. 39, 1283-1311(1927); *Ber. ges. Physiol. expil. Pharmacol.* 44, 801.—The left kidney was generally found to be larger and heavier than the right one. In a given time more urine can be catheterized from the larger kidney than from the smaller one. The concn. of the fixed constituents of urine, NaCl, H_2PO_4 , total N, urea and NH_3 is usually less in the urine from the larger kidney although their abs. amts. are usually larger than in the urine from the other kidney. There is no fixed relation between the amt. of urine and its concn. Indigo carmine and phenol red were usually eliminated more rapidly from the right kidney than from the left. The concn. of the dye is usually higher, but the total amt. is less than that eliminated from the left kidney.

R. C. WILLSON

Experimental studies of the influence of hemolysis on the secretion of bile. KINJI SUGIY AND OZU HISASI. Med. Univ. Okayama. *Okayama-Igakkaï-Zasshi* 39, 1262-13(1927); *Ber. ges. Physiol. expil. Pharmacol.* 44, 779. Using dogs with gall bladder fistulas, the authors studied the effect of splenectomy alone and the injection of hemolyzing substances such as distd. H_2O , hemolysin, phenylhydrazine, nitrobenzene and tolulenediamine, before and after splenectomy, on the amt. and the Fe and bilirubin content of bile. Splenectomy caused a reduction in the amt. of the bile and its Fe and bilirubin content for 20-30 days after the operation, when these values slowly returned to normal. Injection of distd. H_2O or hemolysin (rabbit serum treated thrice with deg. erythrocytes) caused an increase in the amt. and Fe and bilirubin content of the bile both before and after splenectomy. The injection of phenylhydrazine at first causes a slight reduction in these 3 factors but from the 4th day on there is a considerable increase. This was also the case after splenectomy, but to a smaller degree. Nitrobenzene both before and after splenectomy causes an increase in the secretion of bile. Tolulenediamine injected before splenectomy effects an increase in all 3 factors, whereas after splenectomy the bilirubin content was decreased. This study seems to indicate a certain role of the spleen in the extrahepatic formation of bilirubin.

R. C. WILLSON

Studies of the acidity curve of the stomach after buffer-free alcohol test-potion; and remarks on the contents of the fasting stomach. TAKASHI MURAYAMA. Univ. Okayama. *Okayama-Igakkaï-Zasshi*. 40, 520-30(1928); *Ber. ges. Physiol. expil. Pharmacol.* 46, 405.—Ten healthy and 44 sick persons were studied, the Rehfuß tube being used to ext. the fasting contents of the stomach and also the contents after a test-potion of 200 cc. 3% buffer-free alc. soln. The free HCl was detd. with dimethyl yellow and the total acidity with phenolphthalein in the usual way. The fasting healthy stomach contained a rather large quantity of fluid, but it never exceeded 60 cc. The content showed an av. of 27.5 degrees acidity, gave no lactic acid or starch reaction and in many cases contained mucus. Duodenal back-flow was detectable in 60% of the cases. Fractional analysis of the contents after the buffer-free alcohol test-potion

that the titration curves with methyl orange and with phenolphthalein closely ended to those for the normal stomach. Up to about 50 mins. at which time the degree of acidity is usually reached, the difference between the 2 acidity curves is 3-15 degrees acidity. The buffering curve of the stomach appears to be very important for the diagnosis of certain gastric diseases and indeed more for the estimation of their course than for their functional diagnosis. The alc. test-potion is much more suitable for the examination of the gastric acidity than is the Ewald-Boas test-meal, except for the fact that duodenal back-flow occurs more frequently in the first.

R. C. WILLSON

The determination of the pancreatic secretion. SEIZABURO OKADA, EICHI SAKURAI, TSUNAMOTO IMAZU AND KWANICHI KURAMOCHI. *Imp. Univ., Tokio. Proc. Imp. acad.* 4, 131-3(1928); *Ber. ges. Physiol. expil. Pharmacol.* 46, 410.—With a duodenal sound, the stomach being empty, the secretion of the duodenum was removed for 3 hrs. with or without the use of stimulants such as ether, alcohol, H_2O or 0.2% HCl. Trypsin was detd. according to Gross' casein method, amylase with Okada's colorimetric method and lipase with the tributyrin method of Rona-Michaelis. Fifty cases were studied. Results: trypsin under 30 kilo-units, 1 case; from 30 to 120 kilo-units, 48 cases; above 120 kilo-units, 1 case. Amylase: under 50 kilo-units, 1 case; 50-100 kilo-units, 48 cases; above 300 kilo-units, 1 case. Lipase: under 50 units, 5 cases; 50-300 units, 41 cases; above 300 units, 4 cases. (A kilo-unit of trypsin signifies the complete digestion of 1 g. casein in 30 mins.; a kilo-unit of amylase, the production of 1 g. sugar from sol. starch in 15 mins.; a kilo-unit of lipase signifies 1000-fold of the reduction of 20 drops in 50 mins., that is one-half of the difference between a satd. tributyrin soln. and H_2O .) In a 3-hr. study, the use of stimulants makes but little difference, only HCl giving higher values. Results with women are usually lower than those of men; the quantity is also less. Shorter studies are of no value.

R. C. WILLSON

The internal secretion of the placenta. JOSEF PAZOUREK. *Rozhledy chir. gynaekol.* 7, 115-21(1928); *Ber. ges. Physiol. expil. Pharmacol.* 46, 763.—This isolated substance contains the particular hormone which appears to be common not only to the placenta and the corpus luteum but also to all the ovarian glands. Subcutaneous injections of the substance isolated from the human placenta and injected into a castrated mouse can provoke the individual phases of the vaginal cycle, indicating that the human hormone is identical with the animal hormone, at least as far as its action is concerned. The isolated substance which contains the hormone is a yellow, slightly opaque fluid, sol. in alc., ether, acetone and benzene and upon chilling assumes a solid form; it is oxidized in the air. This hormone is resistant to both low temps. and high ones (193°). It is unchanged by the digestive process and remains active since when mice are fed with placenta changes in the vaginal mucous membrane were observed.

R. C. W.

The biochemistry of the sense organs. F. BERENSTEIN. *Russ. Fisiol. Zhurnal.* 9, 205-16(1928); *Ber. ges. Physiol. expil. Pharmacol.* 44, 820.—The eyes of rabbits, sheep, cows and dogs were carefully freed from muscular tissue, cut into small pieces and macerated in a mortar with sterile sand. About 5 cc. sterile distd. H_2O was added for each g. of the organs and extraction made at room temp. for 24 hrs. under a layer of toluene. The enzymes were detd. in the filtrate from this extrn. Amylase was found in all but cow; invertase in all but dog; lactase in none; maltase in none; glucosidase only in dog; urease in none; erepsin in all but rabbit; pepsin in none; trypsin only in rabbit; lipase in none; lecithinase in none; catalase in all; reductase in all but rabbit; oxidase in all; peroxidase in all; alcoholase in none; lactolase only in cow; zymase in none; chymosin in sheep and dog.

R. C. WILLSON

The distribution of the enzymes in the organs and tissues of the animal body. F. BERENSTEIN. *Russ. Fisiol. Zhurnal* 9, 383-94(1928); *Ber. ges. Physiol. expil. Pharmacol.* 44, 821.—The following results were obtained for diff. enzymes in the testicles and ovaries of the dog, ram, bull, sow, ewe, and cow: amylase was found in all; invertase in ram and cow; lactase in none; maltase in none; glucosidase in bull; catalase in all; oxidase in all but dog; peroxidase in all; reductase in all but dog and ewe; lipase in all; lecithinase in ram, bull and sow; erepsin in all but dog; pepsin in dog and sow; trypsin in all; autolytic enzyme in all; urease in none; zymase in none; lactolase in all but dog and ewe; alcoholase in ram.

R. C. WILLSON

The external secretion of the pancreas. BORIS GOLDSTEIN. *Russ. Fisiol. Zhurnal* 11, 23-31(1928); *Ber. ges. Physiol. expil. Pharmacol.* 46, 675.—The actions of secretin and of pilocarpine on the isolated pancreas were studied. When the amt. of secreted juice from the isolated pancreas is less than 1%, both these agents act specifically on the pancreas secretion. Small amts. of secretin (less than 10 cc. of secretin soln. to

1 cc. Ringer-Locke soln.) do not stimulate the secretion of the isolated pancreas. Larger amts. of secretin increase the amt. of the secretion from the isolated pancreas as well as the concn. of enzymes (trypsin and amylase). Pilocarpine does not increase the amt. of secreted pancreatic juice to such a degree as does secretin, but its action on the concn. of the enzymes is stronger than that of secretin. R. C. WILLSON

Studies of the urine of the Marburg Olympian athletes. O. FLOESNER AND FR. KUTSCHNER. Univ. Marburg. *Sitzb. Ges. Beförderung Ges. Naturw. Marburg* 62, 283-93(1927); *Ber. ges. Physiol. expl. Pharmacol.* 46, 228.—The urine of 70 students 30 mins. before the beginning of their contests (400-m. to 10-km. runs and 100-1000-m. swims) totaled 8500 cc., while the first discharges after the contests amounted to 6000 cc. The previously collected urine (U-1) reacted partly neutral and partly acid while that after the contest (U-2) was always strongly acid. In U-1 albumin and sugar were always absent; in U-2 sugar was absent, but albumin was often present in traces. Both urines were divided (U-2 after deproteinization), boiled to a sirup, exhausted with H_2SO_4 soln. and extracted with ether. With steam 1 g. hippuric acid could be produced from U-1 and 0.67 g. from U-2; the smaller amt. of urine in U-2 was compensated for by the higher concn. From the residue after ether extn. in U-1 no crystallizable substances were obtained, but from U-2 came 14.8 g. zinc lactate which corresponds to 0.14 g. lactic acid per person in an av. of 85 cc. urine. From the ether-insol. portion of U-2 there came 0.5772 g. adenine-gold chloride, while xanthine, hypoxanthine and guanine were absent. The cause of this extreme alteration in the metabolism lies in the O deficiency. Arginine was absent in the arginine fraction, but 0.45 g. methylguanidine was found; this corresponds to 13 mg. methylguanidine per l. urine which is much more than normal. In the lysine fraction small amts. of phenylalanine were found; this was formerly found only after P-poisoning. The increased elimination of adenine, methylguanidine and lactic acid, the reduction in hippuric acid and the appearance of phenylalanine are all to be traced back to an extreme deficiency of O in the tissues. R. C. WILLSON

The conduct of calcium during the healing of fractures. JOSE SAGOVIA. *Z. orthop. Chir.* 48, 572-82(1927); *Ber. ges. Physiol. expl. Pharmacol.* 44, 749.—A subcutaneous fracture was reset in each of 5 rabbits, the animals were killed at different periods and the Ca content of the fractured and unfractured parts of the bones was detd. after detaching the soft parts. S found that the Ca content in no stage of the healing of the fracture was greater than in the unfractured part. Conclusion: The Ca for the ossification of callus is obtained from the broken bone itself and not from the Ca in the blood. Objective evidence of this transportation of Ca was seen in atrophy of the bone at other places. R. C. WILLSON

H. GIDEON WELLS

Lactacidogen in experimental pancreas diabetes. M. VON FALKENHAUSEN AND H. HIRSCH-KAUFMANN. *Z. ges. expl. Med.* 58, 567-77(1927).—Lactacidogen metabolism (of dogs) is not disturbed by expl. pancreas diabetes. B. C. A.

Hematoporphyrinuria. H. H. VAN DER ZOO DE JONG. *Geneeskund. Nederlandsche Tijdschr.* 72, 1, 165-8(1929).—The urine of porphyrinuria patients seems to contain urofuscine bound to a brown dye, which serves to detoxify it. The urofuscine-porphyrin compd. decomposes on letting the urine stand as shown by the more intense brown coloration. By adding HCl and heating on a water bath the decompn. is accelerated. In congenital porphyrinuria the compd. is not formed chiefly on account of the excess of porphyrin present. R. BEUTNER

Albuminuria in the mechanism of detoxification. EDMUND ANDREWS, WM. A. THOMAS AND WM. F. WILKER. *Arch. Internal Med.* 43, 139-43(1929).—Human nephritic urine contains normal blood proteins, a relatively nontoxic peptone (which is coagulated with the albumins by heat) and a highly toxic blood protein that is so highly dispersed that it passes readily through a collodion membrane. It is suggested that albuminuria is a detoxicating mechanism for eliminating poisonous products of protein metabolism. J. B. BROWN

The cholesterol content of blood plasma in diabetes mellitus. I. M. RABINOWITZ. *Arch. Internal Med.* 43, 363-71(1929).—Two thousand observations in 385 cases show that the estn. of plasma cholesterol affords a reliable index to the true progress of the diabetic patient. It is suggested that this detn. should be made routine in the control of diabetes. J. B. BROWN

The cholesterol content of blood plasma in juvenile diabetes. I. M. RABINO-

Med. 43, 372-5(1929).—In juvenile diabetes glucosuria is usually hypercholesterolemia. As is the case with adults, the estn. of a reliable index to the true progress of the diabetes.

J. B. BROWN

in the urine of normal and nephritic rabbits. *HIDEICHI Med.* 12, 153-60(1929).—Urine of 3 sets of 4 rabbits

incubated with NH_3 after the production of exptl. nephritis than before. The amount of NH_3 after incubation at 40° for 50 mins. (CHCl_3 , thymol and phenol were used to prevent bacterial action) was greater in the nephritic than in the control urines, to be due to the increase in the ureolytic substance, which has the character of NH_3 in the blood. The larger quantity of NH_3 in nephritis was not due to NH_3 in the blood, but to the production of NH_3 in the kidney.

B. C. BRUNSTETTER

the action of duck serum upon normal and nephritic rabbits. *HIDEICHI Exptl. Med.* 12, 161-78(1929).—Extensive urinary analyses show

parenterally to normal rabbits is markedly diuretic: N excretion no inflammation was caused. Intravenous injection of duck serum

from K_2CrO_7 -nephritis but made rabbits nephritic from injection of $\text{UO}_2(\text{NO}_3)_2$ or cantharidin worse. Conclusion: A moderate dosage of duck serum be of value in the therapeutics of hydropsy when there is no kidney injury.

B. C. BRUNSTETTER

The basal metabolism in hypertension. ENAJI HAYASAKA. *Tôhoku J. Exptl. Med.* 12, 270-80(1929).—Cases of renal diseases with hypertension were classified according to Volhard and basal metabolisms of each type were detd. In 14 cases of benign hypertension the av. basal metabolic rate was -6% (referred to normal values prep'd. by F. B. Sanborn) but in 6 cases of malignant hypertension, the av. rate was $+18\%$. In 7 cases involving secondary contracted kidney, the av. rate was -14% . In one case in the uremic state, the basal metabolic rate was $+27\%$.

B. C. B.

Blood uric acid values in healthy and tuberculous individuals at high altitudes. PAUL BORCHARDT. Univ. Berlin. *Z. Tuberk.* 50, 473-80(1928).—The blood uric acid content of healthy individuals is only 0.7 to 1.7 mg. % at high altitudes compared to 3 to 5 mg. % in lowlands. No difference was noted between men and women. During early febrile disease or tuberculous relapse the uric acid increased with a diminution subsequently. Tuberculous individuals running a favorable course revealed normal values. No relation between the blood uric acid findings and leucocyte counts was observed.

H. J. CORPER

Potential blood alkalinity and its variations in pulmonary tuberculosis. T. D. KAHN. Sanat., Slobodka, Odessa. *Z. Tuberk.* 50, 480-5(1928).—The potential blood alk. is usually diminished in pulmonary tuberculosis, the grade being dependent upon the decompensation of the disease process but being little related to the anatomical Turban stage classification. The diminution is more marked in exudative than in fibroid and productive phthisis. With clinical improvement the potential blood alk. increases while complications, especially involving the kidneys, result in a diminution. The changes in the potential blood alk. are usually inversely proportional to those of the erythrocyte sedimentation and leucocytic index.

H. J. CORPER

The copper content of normal and pathological organs. I. Method. R. SCHÖNHEIMER AND F. OSHIMA. Univ. Freiburg. *Z. physiol. Chem.* 180, 249-52(1929).—Detns. of minute quantities of Cu in animal tissues by the usual methods are possible only with comparatively large samples. A colorimetric microchem. method was therefore devised which is applicable to small samples, e. g., 10 cc. of blood or 5-7 g. of normal liver, or still smaller samples where the Cu content is higher. It is a colorimetric adaptation of the Spæu reaction (C. A. 18, 2300), whereby a green CHCl_3 -sol. complex of Cu-pyridine-SCN is formed. The sample is ashed in a small Kjeldahl flask with H_2SO_4 - HNO_3 , the residue dissolved in H_2O and the Cu pptd. by H_2S . The ppt. and filter are then ashed in a test tube with Neumann's reagent, the residue is dissolved in H_2O , nearly neutralized with NH_4OH , and treated with NH_4SCN and pyridine. The mixt. is finally shaken with CHCl_3 and the CHCl_3 soln. compared in a microcolorimeter with a similar soln. obtained from a known amt. of Cu. The technic is described in detail. With 0.01 mg. Cu the max. error is 5%, and with 0.008 mg. it is 8%, the error increasing with decreasing amts. of Cu. II. The copper content of normal liver and of the liver in hemochromatosis, also that of gallstones and whole blood. F. OSHIMA AND R. SCHÖNHEIMER. *Ibid.* 252-8.—By the method outlined above Cu detns. were made on a considerable no. of human livers for comparison between normal and pathological conditions. Parallel detns. of Fe are reported in most cases. Six samples of gallstones showed 0.0438 to 0.237% Fe and 0.0159 to 0.206% Cu. Normal livers varied between

0.022 and 0.089% Fe, and between 1.32 and 3.92 mg. Cu per liver; on the other hand, contained 0.70 to 3.26% Fe and 0.01 to 0.03% Cu. Both Fe and Cu show an enormous increase over the normal value which showed 1.13 to 1.44 mg. Cu per kg.

Immunity and convalescence. B. V. ISSAKUTA. *Pharmazie* (1929).—An address in reference particularly to poisons.

A preliminary note on the decolorization of a solution of methylene blue left in contact with kala-azar serum. T. C. BOYD AND A. C. BOYD. *Indian Med. Gaz.* 63, 568 (1928).—When solns. of methylene blue are left in contact with a soln. of methylene blue contg. 1 part of the dye in 40,000 parts of water, colorization is discernible on the 3rd or 4th day; the addn. of a microorganism together inhibits the reaction. The presence of a microorganism may account for the fading observed. Further work on this subject.

A critical examination of the antimony tests for kala-azar. Kala-Azar Commission. *Indian Med. Gaz.* 63, 687-97 (1928).—Close the fact that the Sb test is much more delicate than that in which the aldehyde reaction is employed. Unfortunately, the former is not pos. in every case of kala-azar. The changes occurring in the serum of the patient affected with this disease occur also to a less extent in the serum of those suffering from malaria of the chronic type and certain other conditions of splenic enlargement; also, in phthisis and leprosy. Because of these conditions, the delicacy of the reaction is a distinct disadvantage. Rules are suggested to make the test one of clinical value. The dilution method is discussed, as are also the various diagnostic aspects encountered during treatment. It is suggested that a diagnosis be made on the combined results of the 2 tests. When either method is used alone, the results of the blood test are entirely unsatisfactory. F. G. G.

Homogentisuria (alkaptonuria) with glucosuria. J. P. BOSE AND SUDHAMOY GHOSH. School of Tropical Med., Calcutta. *Indian Med. Gaz.* 64, 61-6 (1929).—An extremely rare disease occurring in individuals, otherwise normal, whose urine, though of perfectly normal color when voided, turns black when exposed to the air, especially if rendered alk. The chem. compn. of several compds. whose presence is believed to be responsible for this abnormality is described in detail. It is believed that homogentisic acid (2,5-dihydroxyphenylacetic acid), a substance present in urines of the character described, is derived from phenylalanine and tyrosine in the system. Protein foods cause an increase of this acid in individuals so affected. Derivs. of homogentisic acid have been prepd. FREDERICK G. GERMUTH

Indican determination in the urine of diagnostic value? J. OLIVET. *Klin. Wochschr.* 7, 2439-40 (1928).—The amt. of indican in the urine is not an index of intestinal putrefaction. The indican probably originates in the intestine but other factors, such as destruction of indican by the body tissues, confuse the end result. Twenty-four-hr. specimens of urine may contain widely different amts. of indican on successive days although the condition of the patient has remained unchanged. MILTON HANKE

Enterotropie and the parenteral action of cholera poison. III. MARTIN HAHN AND JULIUS HIRSCH. *Klin. Wochschr.* 7, 2483-4 (1928).—The intravenous injection of cholera poison into rabbits leads to profuse diarrhea, fall in body temp., a loss of fluid amounting to 10-17% of the animals' body wt. and death within a few hrs. The microscopic picture of the intestines is identical with that obtained when the animals are infected with the cholera vibrio. Cholera poison is inactive when given by mouth or when it is injected into the lumen of the intestine. An isolated piece of intestine is paralyzed by cholera poison. The intestine is not affected when the poison is allowed to flow through the lumen of the intestine without coming in contact with the outside wall. MILTON HANKE

The existence of a histamine-like substance in cases of dermatographia. HEINZ KALE. *Klin. Wochschr.* 8, 64-6 (1929).—An intensive irritation to the skin of the back leads to the production of a substance which, like histamine, acts as a gastric secretory stimulant. MILTON HANKE

The relation between the colon bacillus invasion of the small intestine and liver therapy in pernicious anemia. H. ADLER, P. SINGER AND P. REIMANN. *Klin. Wochschr.* 8, 724 (1929).—Liver ext. is bactericidal to colon bacilli if a sufficient concn. of the liver ext. is present. The various com. preps. differ in this respect. The most effective was bactericidal in 5% concn., the least effective in 35% concn. It is possible to prep. an ext. that is effective in 2% concn. MILTON HANKE

by work and exhaustion. Increase of magnesium ONHARD WACKER. *Klin. Wochschr.* 8, 244-9(1929); activity was induced in rabbits, under urethan

The Ca and Mg contents of the serum were ele- his stimulation. The excess of these ions disappears Ca and Mg ions that appear in the blood during the ivity probably originate in the muscles and they may muscle by the acid that is produced at this time. Rigor its about 3 hrs. after death. The electrically stimu- mins. A normal period of 3 hrs. is obtained in animals that have then been allowed to recover for 3 hrs. The

relation between the Ca and Mg content of the serum and the phenomenon of rigor mortis is obvious.

MILTON HANKE

The behavior of the thyroid during pregnancy and the reaction of Reid Hunt. R. BRÜHL. *Klin. Wochschr.* 8, 254-5(1929).—The blood of pregnant women does not protect mice against intoxication with acetonitril. This blood does not, therefore, contain substances such as are found in Basedow's disease.

MILTON HANKE

The behavior of the adrenaline-blood-sugar curve in hepatopathics with parenchy- mal involvement. BERNARD KUGELMANN. *Klin. Wochschr.* 8, 264(1929).—Although the injection of adrenaline leads normally to an elevation in the blood-sugar value, this is not true of hepatopathics with parenchymal involvement.

MILTON HANKE

Circulatory insufficiency and muscle metabolism. KURT DRESEL AND FRED HIMMELWEIT. *Klin. Wochschr.* 8, 294-6(1929).—The lactic acid content of venous blood from the arm of a normal individual is not appreciably changed when the arm is mildly exercised. The lactic acid produced by the muscular activity is either promptly oxidized or resynthesized to glucose. This is not true of persons afflicted with circulatory diseases, Basedow's disease or myasthenia. In these cases even the mildest exercise leads to an increase in the lactic acid content of the blood.

MILTON HANKE

Several cases of so-called bent-leg in sheep. A. D. THOMAS. Veterinary Re- search, Onderstepoort. *S. African J. Sci.* 25, 278-81(1929).—A few cases of bent- leg were observed in a large herd of sheep. The P_2O_5 and CaO contents of the fodder were known to be small, though they compared favorably with the general condition prevailing in South Africa. Conclusion: The disease cannot be attributed to a faulty balance in the mineral constituents of the diet. Heredity could be the cause.

ALBERT L. HENNE

Activation of proteolysis in animal organs, its significance for the metabolism of malign tumors. R. WALDSCHMIDT-LEITZ, I. J. BEK AND J. KAHN. *Techn. Hochschule Prag. Naturwissenschaften* 17, 85(1929).—The proteolytic system of animal organ (previous expts. on spleen, stomach, liver and kidney) consists of (1) an enzyme, opti- mum pH 4 to 5 which attacks genuine protein and (2) in larger amt. a peptidase, opti- mum pH 8, the latter being similar to the one of the digestive tract (cf. C. A. 21, 3061). The protease of the spleen, hemokathepsin, is accompanied by a natural activator formed by traces of autolysis, which enlarges the range of attack of the enzyme. B sepn. of enzyme: self itself only splits (adsorption method) it could be shown that the enzyme itself decomposes products whereas the activator enable

it to attack protein (egg albumin), gelatin or protamines to that of Grassmann and Dyckerhoff's yeast proteinase. The action of the activator can as well, in some cases even more effectively, be replaced by H_2S or HCN addn. to the enzyme. Proteins, acylated peptides, acetyl tyrosine, benzoyldiglycine, carbethoxyglycylleucine, etc., are attacked by the enzyme. In its action toward these synthetic products the enzyme is similar to trypsin, chymotrypsin, or papain; identity of the enzymes is for this reason not certain. The results merely indicate similar action on isoelec. protein. It is probable that a similar relation may exist between inhibitive action (of HCN or other substances) and activating effects on proteolysis as, e. g., that found in the case of trypsin caused by the same substances. An explanation of the connection between these cell degenerations by specifically increased proteolysis and the theory of progressive damaging by anaerobically formed products is not yet clear.

Calcium fixation capacity of normal and rachitic cartilage. J. K. HARRIS. Univ. Würzburg. *Z. Biol.* 87, 537-42(1928).—In order to test the fixation capacity of cartilage, specimens were soaked for 24 hours in $CaCl_2$ soln. The tissues tested included calf epiphysis, cattle rib and shoulder cartilage, proliferating and non-proliferating zones of calf rib cartilage, rachitic and non-rachitic cartilage from children and proliferating and non-proliferating zones of cartilage from rachitic children. No relationship was noted between Ca fixation and calcification.

"Retention" of residual nitrogen and aromatic bodies in the blood and its anatomical localization in experimental renal insufficiency. MARJAN FRANK. *Med. Périodica* 9, 219-23 (Polish), 224 (French)(1928).—In exptl. renal change in dogs the high level of residual nitrogen (RN) and aromatic bodies (CA) is an inseparable symptom of a general grave state and of a considerable pathol. affection of the kidney, especially the renal epithelium. RN and CA of the blood in these cases running parallel though the multiplicity of the increase of these two groups is not the same which is due to their different origin. The anatomic cause of the increase of RN and CA in the blood in exptl. renal insufficiency is a pathol. state of the epithelium of the tubules of the kidney.

The effect of ligation of the common bile duct upon the appearance of tetany in thyro-parathyroidectomized dogs. JOHN C. BROUGHER. Univ. of Oregon Med. School. *Am. J. Physiol.* 86, 39-42(1928).—Obstruction of the common bile duct by tying prevented the appearance of typical parathyroid tetany in dogs. The result may have been due to (1) a lessened excretion of Ca from the body by way of the bile, (2) increase in absorption of Ca from the intestine because of the absence of the alk. bile salts; (3) depression of the nervous system by the absorbed bile.

The conditions of activity in endocrine glands. XXV. The polycythemia of acute anoxemia and its relation to the sympathico-adrenal system. J. J. IZQUIERDO. Harvard Univ. *Am. J. Physiol.* 86, 145-59(1928).—Normal cats kept for 50 min. period in a low-pressure chamber (5.5 to 9% O_2) without emotional excitement breathed rapidly with shallow respirations, and the red blood cell count increased markedly. Removal of the spleen was followed by a failure of the red blood cells to increase in anoxemia. CO_2 in the air (even up to 20%) had little or no effect on the red blood cell count.

The acid-base equilibrium of bilaterally nephrectomized and adrenalectomized dogs. W. W. SWINGLES. State Univ. Iowa. *Am. J. Physiol.* 86, 450-8(1928).—After removal of both kidneys from dogs there was (1) marked increase of sulfate, phosphate and urea in the blood; (2) an increased blood sugar; (3) diminished blood chlorides; and (4) no acidosis. After removal of both adrenals there were no changes in the blood constituents until symptoms developed. A marked acidosis then appeared, due apparently to retention of phosphate and sulfate. S. believes that the symptoms of adrenal insufficiency are simply those of a slowly developing acidosis. J. F. L.

The acid intoxication of adrenal insufficiency in dogs. FREDERICK F. VOCKMAN. State Univ. Iowa. *Am. J. Physiol.* 86, 471-83(1928).—After removal of both adrenals from dogs there was a marked acidosis, appearing with the first development of symptoms and accompanied by a retention of nitrogenous constituents, inorg. phosphates

is indicated as a direct consequence of the loss

J. F. LYMAN

serum diagnosis of lues. CESARE CLIVIO. *Boll. soc.*

8).—Out of 574 serums tested, 460 agreed exactly with the Wassermann and 345 neg. In 34 samples it was not possible to make a definite diagnosis because of the presence of corpuscles which clouded the tubes. In only 10 cases was there a disagreement between this test and the Wassermann. Of these, 7 were pos. but acetic anhydride neg. The remaining were 78 Wassermann pos., and of these only 3.35% or 18 cases showed positive results.

The technic of the test is as follows: to one cc. of physiological saline add 0.1 cc. of pure acetic anhydride and boil. Then add 0.1 cc. of the serum to be tested while still boiling. A pos. reaction quickly assumes a

pinkish color which changes to violet or carmine red. If the reaction is neg. the serum remains uncolored or may assume a pale mauve color later. The

test is read when the first tint appears, and 15 min. later when the color assumes the maximum intensity. Activated serums give a tint which makes it difficult to differentiate between the positives and the negatives, and, therefore, cannot be used. Guinea pig complement does not give the reaction. The reaction is pos. with egg albumin and egg yolk.

PETER MASUCCI

Experimental study of acquired resistance of the rabbit's renal epithelium to mercuric chloride. WARREN C. HUNTER. Univ. of Mich. *Ann. Internal Med.* 2, 789-806(1929).—HgCl₂ is not a satisfactory substance for use in the production of immunity in renal epithelium because of irregularity of absorption and local corrosive action following subcutaneous administration. There is danger of thrombosis and enterocolitis after intravenous injection. A slight degree of immunity can be demonstrated in regenerated epithelium and glomeruli. Glomerular injury is less frequent than in the normal kidney. A characteristic finding is the envelopment of neurotic cells by regenerating epithelium. In the rabbit, Ca deposition in casts is inconstant. JOHN T. MYERS

Report of a case of primary multiple myeloma with Bence-Jones protein in the pleural effusion. EUGENE E. MARCOVICI. *Ann. Internal Med.* 2, 881-911(1929).—In this case Bence-Jones protein was present in the pleural effusion before it appeared in the urine. There is a bibliography of 120 titles. JOHN T. MYERS

Familial glucosuria. Report of a large family. HAROLD M. BOWCOCK. *Ann. Internal Med.* 2, 923-31(1929).—Eighteen members of a family from 4 generations, representing 58% of the members studied, showed glucosuria without symptoms of diabetes mellitus. The blood and urine of 5 of the cases were studied. One case had the findings of mild diabetes, 2 those of renal glucosuria, and 2 those of cyclic renal glucosuria. JOHN T. MYERS

Focal calcification of heart muscle; case report. VINCENT DE PAUL KING. *Ann. Internal Med.* 2, 936-40(1929). JOHN T. MYERS

The effect of bone transplantation on the blood calcium level. GEORGE HALPERIN and E. L. WALSH. Northwestern Univ. *Arch. Surg.* 13, 819-23(1929).—Homologous bone transplants fail to raise the level of the blood Ca in normal dogs and rabbits. The blood Ca level is not as const. in rabbits as it is in dogs. JOHN T. MYERS

The relationship between the hemolytic complement and the opsonic power of normal guinea pig serum. JOHN GORDON, HUGH R. WHITEHEAD and ARTHUR WORMALL. School of Medicine, Leeds, and Coll. of Medicine, Newcastle-on-Tyne. *J. Path. Bact.* 32, 56-61(1929).—Destruction of the normal hemolytic power of guinea pig serum with NH₃ does not reduce to a significant extent the opsonic power of the serum for *Staphylococcus aureus*. Incubation of the normal serum at 37° for 2 hrs. with this organism in amounts sufficient to remove hemolytic and opsonic power does not remove the fourth component of complement; hence the fourth component is not necessary for the opsonic action of normal serum. JOHN T. MYERS

A case of diabetes mellitus with acromegaly and lipemia. JOHN GRAY. Aberdeen Univ. *J. Path. Bact.* 32, 71-7(1929). JOHN T. MYERS

Siderosis of the globus pallidus: its relation to bilateral necrosis. GEORGE HADFIELD. General Hosp., Bristol, and Royal Free Hosp., London. *J. Path. Bact.* 32, 135-48(1929).—The walls of the blood vessels of the healthy globus pallidus are often infiltrated with Fe salts derived from the nucleus itself. It is likely that the process is one of evolutionary atrophy. It predisposes to the acute bilateral destruction of these nuclei which are frequent in coal-gas poisoning. JOHN T. MYERS

Experiments on the nature of the carcinogenic agents in mineral oils. C. C.

TWORT AND J. D. FULTON. *J. Path. Bact.* 32, 149-61(the carcinogenic oils the active agent is sometimes the lower fraction. The active agent is concd. in methyl sulfate and picric acid, and the process is useful. There is no evidence that carcinogenic substances are or by extn. The carcinogenic activity of an oil is much by extn. with H_2SO_4 , oxidation, and by reduction.

Demonstration of the peculiar bodies of bodies") in material obtained by lung puncture and AND A. C. HADDOW. *J. Path. Bact.* 32, 172(1929).-yellow bodies were found in two cases of pulmonary had worked with asbestos for several years.

Improvement of diabetes in a pregnant woman. RENCE. King's Coll. Hosp. *Quart. J. Med.* 22, 11, twin pregnancy in a diabetic woman was studied. Up pregnancy the sugar tolerance deteriorated. From the of pregnancy it improved to the extent of 100 g. of carbohydrate per day. This tolerance was not maintained after labor and must be ascribed to fetal insulin aiding the mother. The renal threshold was lowered at the sixteenth week and returned to normal at the thirty-fourth week. There was no increase in ketosis or change in the fatty acid: glucose ratio tolerated. The pregnancy was complicated in the later months by a salt retention edema and a parenchymatous nephritis. JOHN T. MYERS

Febrile albuminuria with special reference to pneumonia. L. C. HILL. (*Quart. J. Med.* 22, 305-19(1929). -Albumin is present in considerable quantities in every case of pneumonia at some time during its course. The presence of a trace may be of diagnostic value in a doubtful case. The degree of albuminuria corresponds broadly with the height of the temp., but persists for some time after the temp. has dropped. There is no correlation between albuminuria and temp. during such complications as empyema or mastoid suppuration. There is no definite relationship between the quantity of urine secreted and the degree of albuminuria, though they tend to be inverse. On the whole the intensity of the albuminuria is proportional to the severity of the case. Large numbers of casts indicate an unusually severe attack. There is an increase in the intensity of the albuminuria just prior to death. The temp. is not the cause of the albuminuria. It is probable that febrile albuminuria in the strict sense of the word does not exist, but that there is always some renal damage. The kidney in such albuminurias shows degenerative changes but not inflammation. JOHN T. MYERS

Biocatalyzer in carbohydrate metabolism of cancer. H. V. EULER AND H. JOHANSSON. *Swensk Kem. Tids.* 40, 209-18(1928). (In German); cf. *C. A.* 23, 1. The corymase technic developed in v. Euler's lab. (*C. A.* 21, 2138, 1820, 1905), was applied to carcinomatous human liver tissues and compared with results from normal tissues of the same organ. The inhibiting factors of the pathol. cells have an effect on the "A-Z" (activator zymase units, i. e., cc. CO_2 per hour per g. dry matter of tissue). Tests with exts. from cancer liver gave A-Z value under 300 whereas the normal exts. exceeded this no. A-Z nos. were also obtained from hashed and desiccated organs; for the former the normal came to 30 and over and the pathol. 20, and for the latter 27 and 13, resp. The A-Z units could be concd. sevenfold by a procedure previously described (*C. A.* 22, 2384, 3671). A. P. LESTER

Histochemical researches on pulmonary anthracosis. A. POLICARD, S. L. BROW AND D. PILLET. *Compt. rend.* 188, 278-9(1929); cf. *C. A.* 22, 2062. The 2 varieties of pulmonary pigments, namely, the ferruginous one derived from the blood and the one consisting of exogenous C may be distinguished by micro-incineration or by microscopical examn. The C deposits contain also particles of minerals like carbonates, silicates, feldspars, etc. The residue obtained by igniting the C particles has a greater double refraction than had the original particles on account of the heat causing the silicates to crystallize and thus to become anisotropic. The pigments are isolated by destroying the pulmonary tissue with a strongly alk. soln. of $NaOCl$. The ferruginous particles, which may be dissolved by strong hot acids, sometimes include crystals of hematin or cholesterol esters; in order to distinguish them from inorg. crystals they are heated, by which process the org. crystals are destroyed. G. SCHWARTZ

The total proteins (serum albumin and serum globulin) in sera of guinea pigs with scurvy. The presence of albumin and hemoglobin in the urine of these in the last stage of the disease. (MILAN.) A. MICHAUX. *Compt. rend.* 188, 853-4(1929).-In guinea pigs suffering from scurvy (I) the total protein in the serum was detd. from the 10th to the 32nd day after starting them on a scurvy-producing diet.

d were compared with the corresponding values from guinea and guinea pigs on a complete, synthetic diet (III). The values were slightly lower than those in II. The values found in I and in other except on the 16th day and the next few days therein in I were considerably lower. On the days preceding the appearance of albumin and hemoglobin were present in their urine. Globulin was found to be sensitive to a diln. of 1:100,000,000.

G. SCHWOCH

and pathological sera (oxidizability of sera). R. DOURIS, M. PLESSIS. *Compt. rend.* 188, 587-8 (1929); cf. C. A. Power of normal and pathol. sera was examd. in the following: 1 cc. serum and 9 cc. H_2O was boiled for 2 mins. with 1 cc. of concd. H_2SO_4 and 9.80 g. of $K_2Cr_2O_7$ per l. After cooling the $K_2Cr_2O_7$ in excess was detd. by titration with a 0.2% $K_3Fe(CN)_6$ being used as an outside indicator. The values for 1 cc. of serum were 128-44 in normal sera, 80-120 in syphilitic sera. A diagnostic method based on this procedure

G. SCHWOCH

hemolysis. K. C. SEN, A. C. RAY AND N. N. MITRA. *Univ. Sci. Bull.* 42(1929).—Sachs (C. A. 3, 1549) showed that the hemolysis was accelerated if normal blood serum was subjoined to the hemolysate. Ponder (C. A. 18, 2727) obtained similar results with taurocholate. In continuation of earlier studies (Sen and Mitra) found that in expts. conducted with oleate and taurocholate quantities of serum added to an erythrocyte-hemolyte suspension caused inhibition; larger amounts, however, caused acceleration.

Effect of serum on hemolysis. This effect of serum is not specific, since dil. solns. of NaOH had a similar effect. The action of serum may be due to a change of the pH produced by the serum proteins. No acceleration of hemolysis could be obtained with saponin as the hemolyte.

G. SCHWOCH

Biochemical study of the adder venom. III. CHOKURO KUBAYASHI. *Osaka Med. Col. Osaka J. Med.* 27, 770-80 (1928). The effect of venom upon the substance in the blood of a rabbit which reacts with iodate is studied. A subcutaneous injection of the min. quantity of the venom for poisoning (0.001 g.) or for the fatal quantity (0.003 g.) was given to a rabbit weighing 2 kg., the reagent being dissolved in 1 cc. of distd. H_2O . The variation of the substances reacting with iodate was examd. at various time intervals. In poisoning, the substance which reacts with iodate gradually decreases, returning to the normal condition with the disappearance of the poisoning symptom. With the fatal quantity the decrease is a little more rapid and continues just up to the moment of death. When the poisoning quantity is repeatedly injected with the time interval of 7-10 days, the decrease becomes less and less marked. V. VII. *Ibid* 1405-10, 1411-8.—When the poisoning quantity, 0.001 g., is subcutaneously injected, the increase of the residual N in the blood is gradual and appears to be parallel with the progress of the symptom. The urine contains a weakly acidic protein and some blood pigment, together with some blood sugar, but it contains no urine sugar. With the disappearance of the symptoms, the residual N returns to the normal condition, the urine becoming alk. and the proteins and the blood pigment disappear. When the fatal quantity, 0.003-0.009 g., is injected, the increase of the residual N reaches a max. at the moment just before death and may sometimes reach double the amt. in the normal condition. In the urine, sugar also appears. When the fatal quantity or more of the venom is heated at 37° for more than 1 hr. in the medium whose pH value is 4.15-9.97 the poisoning effect does not decrease markedly. Heating in the medium of pH 2.96 or 11.08 makes the local poisoning action weaker, while at pH 1.06 or 12.95 the poisoning action disappears. VIII. *Ibid* 1725-30.—K. describes some attempts at the sepn. of the venom. This substance does not pass through a collodion membrane; the lecithin decomn. products ppt. with globulin when salted out by means of $(NH_4)_2SO_4$. The substance which poisons the whole body of the victim is present with albumin. The former is easily destroyed in a weakly alk. soln. while the latter is weak in its resistance toward alkali.

K. SOMEYA

The action of certain aldehydes upon diphtheria toxin and upon experimental diphtheria. C. H. PICO AND J. M. MIRAVENT. *Rev. inst. bacteriol. anal. hig.* 4, 695-702 (1920).—Diphtheria toxin was destroyed when mixed with ACH, valeric aldehyde or benzaldehyde *in vitro*. The addn. of formaldehyde to diphtheria toxin *in vitro* destroyed the toxin but preserved the antigenic properties. A very active anatoxin

was obtained by the addn. of formaldehyde to the toxin

General metabolism in uterine carcinoma. I. Int. N. LOUROS AND E. GAESSLER. Staat. Frauenklinik, Dresden. 191-218(1929).—The first of a proposed series of articles, in general features of metabolism in cancer and a review of the 15 cases of cancer of the cervix in various stages. The findings in the blood, reduced surface tension and increased viscosity values from f.p. determinations, increased rapidity of alkali reserve, increased plasma vol., slight increase in total abs. and relative increase in fibrinogen, moderate abs. and corresponding decrease in albumin, regularly an increase in total cholesterol of the blood, normal values for lactic acid and sugar, NaCl, marked decrease in K, normal Ca, slight increase in metabolism. These results are discussed at length, and a lack is thought to be responsible for much of the observed changes for therapy on this basis.

H - PHARMACOLOGY

A. N. RICHARDS

Solganol treatment. A clinical contribution to gold treatment in pulmonary tuberculosis. A. FREUND. Hasenheide, Berlin-Neukölln. *Beitr. klin. Tuberk.* 68, 606-24(1928).—Solganol is less toxic than other Au preps. Injury to the kidney was never observed, while exanthemas of the skin and mouth mucus membranes were frequent, but retrogressed rapidly under adrenaline treatment. The action of Solganol is similar to that of Sanocrysin but is better tolerated. Favorable results attained in fresh forms of pulmonary tuberculosis while in chronic cirrhotic cases a bare action was observed.

H. J. CORPSE

Problems of chemotherapy in tuberculosis. A critical review. F. JESSEN. *Beitr. klin. Tuberk.* 68, 711-3(1928). J reviews the various endeavors of chemotherapy in tuberculosis and arranges them in three types: (1) an attempt to destroy the tubercle bacilli without injuring the tissues (a *therapia magna sterilisans*), which he believes not likely attainable; (2) an endeavor to retard the spread and development of the tubercle bacilli in the body (as exemplified by the dietetic treatments of Gerson, Hermannsdorfer and Sauerbruch); and (3) endeavors to reinforce the immunologic resistance of the organism (such as Walbum's metal salt therapy).

H. J. CORPSE

Combined febrile and expectorant treatment in pulmonary tuberculosis. MAX BAUMWELL. *Z. Tuberk.* 50, 229-31(1928). Neo-Toramin (trichlorobutylmalonic acid dimethylaminophenyldimethylpyrazolone) is recommended as a combined antipyretic and expectorant treatment. Its effects are obtained without the associated undesirable actions of the narcotics of the morphine group. Neo-Toramin possesses the advantage over pyramidone in producing antipyretic effects with a smaller dose. It also possesses the advantage of not acting directly on the heat center and thus avoiding the harmful excessive perspiration occurring with pyramidone as the result of its action on the sleep center. Focal and general reactions in pulmonary tuberculosis have never been observed.

H. J. CORPSE

The influence of insulin and adrenaline injections on the formation of conjugated glucuronic acids. AKISUKE MATSUMOTO. *Acta Schol. Med. Univ. Imp. Kioto* 10, 271-6(1928).—The excretion of trichloroethylglucuronic acid by dogs after injection of chloral is not affected by the injection of insulin or adrenaline.

DAVID DAVIDSON

Pharmacological investigation with strips of the outer and inner layers of the heart ventricle. I. Poison especially affecting the myocardium. JUN TAKAHASHI. *Schol. Med. Univ. Imp. Kioto* 10, 353-60(1928).—A strip of the outer and inner layers of the heart ventricle of *Rana esculenta* can perform automatic contraction. The impulse-conducting bundle of the ventricle develops mainly in the inner part and the left side. BaCl₂, helleborein, and strophanthin act mainly on the heart muscle but they still have an influence on the impulse-conducting bundle. BaCl₂ can cause the periodic contraction of the heart muscle without relation to the impulse-conducting bundle. The impulse-conducting bundle has a property resembling that of the heart muscle concerning the action of the above-mentioned substances. The difference in the actions of these substances on the outer and inner strips is as follows: Helleborein and strophanthin increase the amplitude of the contractions, the frequency and the tonus of the inner strip with more dil. concns. than those of the outer, and the difference

by the increase of the tonus. The cessation of the con-
dil. concns. on the outer strip than on the inner. That is
ter strip is somewhat feebler than that of the inner. It is
sensitive to BaCl_2 and can be acted on with more dil. concns.
The strength of its contractions is feeble by nature, so that
its tonus increases less and falls into cessation earlier." II.
The autonomic nervous system and aconitine. *Ibid* 361-5.—
atropine and pilocarpine are just the same on the outer and
entricle [of the frog]. Therefore, it is considered that the
autonomic nervous system in the outer and inner strips is nearly
its very distinct action on the inner strip; therefore, it is
the impulse-conducting bundle." DAVID DAVIDSON

The oligodynamic power of copper by solutions of electrolytes—
ra. P.-L. VIOLE AND A. GIBERTON. *Compt. rend.* 188,
"dies in several hrs. in a mixt. of equal parts of distd.
allowing 250 cc. H_2O to stand in contact with 5 g. of Cu

or Saint Nectaire the fish are still alive in it after 24 hrs. This result is not affected
by the ultra-filtration of the mineral waters. The "vairon" lives in 0.01 N Na_2SO_4 ,
 NaHCO_3 , CaCl_2 and MgCl_2 , but dies when these are diluted with the Cu soln except with
 CaCl_2 . The antitoxic action of the mineral waters is therefore attributed to Ca^{++} .
The effective agent in the Cu soln is positively colloidal $\text{Cu}(\text{OH})_2$. Anions of multiple
charge protect this colloid. Among the cations, Na, K, Mg and Sn are not actively anti-
toxic; only Ca is tox antitoxic; Ce, Fe and Al in dilns in which they are tolerated by the fish
are not antitoxic toward the Cu soln

DAVID DAVIDSON

The chemism of adrenaline action. I. S. EDLHACHER AND J. KRAUS. Univ.
Heidelberg *Z. physiol. Chem.* 178, 239-49 (1928). In order to gain some insight
into the chem. reactions whereby adrenaline exerts its sp. effect on animal metabolism,
a study was made of its behavior toward amino acids. In the presence of adrenaline
a slow stream of O or air breaks up glycine with liberation of equimol proportions of
 NH_3 and CO_2 . The max. yield was 45% of the theory; the only other product identified
was a trace of CH_3O . This reaction occurs over a p_{H} range of 6-11, with optimum
at 7.7. At 38° an equil. is reached in about 12 hrs., after which a further addn. of ad-
renaline has little effect. In the absence of O , or when the glycine or adrenaline is
nated separately, no NH_3 or CO_2 is formed. Oxidation occurs more readily in dil.
than in concd. solns. of glycine. Although increasing concns. of adrenaline give in-
creasing yields of the cleavage products, the mol. performance ratio diminishes. Thus,
25 cc. 0.02 N glycine soln. contg. buffer and 1-125,000 adrenaline yields 1.6 cc. 0.02
N NH_3 or a cleavage of 20 mols. of glycine per mol. of adrenaline, whereas a similar
soln. contg. 1-270 adrenaline yields 2.3 cc. of 0.02 N NH_3 or a cleavage of 0.42 mols.
of glycine per mol. of adrenaline. Over the temp. interval from 20° to 70° the reaction
increases almost in proportion to the rise in temp. Other amino acids, viz., alanine,
valine, leucine, *dl*-phenylalanine, tyrosine, lysine, arginine, histidine, tryptophan,
dl-proline, cystine and taurine, with the possible exception of cystine, yield only traces
of NH_3 . Glycylglycine, however, undergoes an oxidation, but the NH_3 formed is
far in excess of the CO_2 . Uric acid, adenine, guanine, hypoxanthine, thymine, uracil
and creatinine fail to react. Adrenaline is apparently a catalyst which is sp. for the
oxidation of glycine by mol. O . Catechol acts in precisely the same way as adrenaline.
Its isomers, *m*- and *p*- $\text{C}_6\text{H}_4(\text{OH})_2$, as well as ephedrine and guaiacol, are inert. The
presence of NaF , NaBr , KI , H_3AsO_3 , KSCN , MnSO_4 , FeCl_3 or urethan does not
appreciably influence the reaction. It is probable that both adrenaline and catechol
function as oxidation catalysts in this particular reaction by rearrangement to an *o*-
quinonoid structure.

A. W. DOX

The action of sulfur on carbohydrate metabolism. EUGEN FOLDS. *Z. ges. exper.*
Med. 60, 571-82 (1928).—Following the rubbing of S into the ears of rabbits there is a
hypoglycemia (20-45% below the controls) lasting from 1 to 4 days. Continued
applications resulted in a hyperplasia of the suprarenals and an increase in the glycogen
content of the liver. Adrenaline produced a hyperglycemia. In one rabbit adrenaline
produced a hypoglycemia and death. This rabbit did not have hyperplasia of the
spleen nor any increase in the glycogen content of the liver. F. L. DUNN

The location of the insulin effect in muscle. M. BURGER AND H. KRAMER. Univ.
Kiel *Z. ges. exper. Med.* 61, 449-64 (1928).—The effect of clamping the iliac and sub-
clavian arteries in dogs on the blood sugar was studied following the injection of insulin.
The hypoglycemia was only slight when the vessels were clamped but on release a sharp

hypoglycemia occurred. B. and K. conclude that inan musculature.

Action of hexetone on respiration. P. GUNS. *Arch. intern. pharmacodyn.* 33, 380-99(1927); *Physiol. Abstracts* 13, 158; cf. C. A. 22, 1 in chloroform narcosis. It is only in light ether narcosis on respiration. This is of no practical interest. The are due in part to the salicylate. Rabbits were used. varies somewhat from 5 to 10 mg. or more per kg. in chl.

The action of histamine on the heart with certain pharmacodynamic 33, 409-19(1927); *Physiol. Abstracts* Ca histamine fails to affect the sympathetic and dimin effect is less on the atropined heart, which suggests that. The supposed pilocarpine-like action of histamine on the accord with its lack of effect on the isolated atropined heart trope effect in the absence of Ca. Histamine in present in its absence vagotrope. The action of histamine on bl previous introduction of Ca. The action of Sr, Ba and Mg

H. L. D.

Physiological study of some derivatives of homocholine, the methyl ether of γ -phenylhomocholine. A. SIMONART. *Arch. intern. pharmacodyn.* 34, 15 (1928); *Physiol. Abstracts* 13, 262. Expts on chloralosed cats in which the central nervous system is destroyed show that the methyl ether of γ -phenylhomocholine is deprived of muscarine-like properties. It exhibits, on the contrary, a marked nicotine-like effect in excitation of vegetative ganglia, followed by their paralysis. On the frog it has the same effect as nicotine, causing contracture and a condition like that due to curare on skeletal muscles. This action on skeletal muscle is also easily demonstrated on the eel. The effects are confirmed by expts. on the blood pressure, and by ocular and splan reactions.

H. L. D.

Experiments with strychnine. W. BURRIDGE. *Arch. intern. pharmacodyn.* 34, 105-12(1928); *Physiol. Abstracts* 13, 261. (1) Strychnine perfused in very small concn in unbalanced soln is a strong cardiac stimulant. (2) Large amts of strychnine are markedly depressor. (3) The effects produced by strychnine vary according to the perfusing soln. Hence, any experimenter working with a single perfusing soln, even though it be the best he knows, will only see through it a portion of the picture of drug's actions on the heart. The use of a single perfusing soln being common, it may well be that many gaps exist in our knowledge of the cardiac action of strychnine.

H. L. D.

Experiments with quinine. W. BURRIDGE. *Arch. intern. pharm.* 34, 113-8(1928); *Physiol. Abstracts* 13, 261. Quinine exerts two groups of cardiac actions of concn and reactions of diln. Concn reactions are depressor. Diln reactions are augmentor. Speculation is indulged in concerning the possibilities of the exploitation of the two groups of actions.

H. L. D.

Action of synthalin. H. J. ARNDT, E. MÖLLER AND E. SCHEMANN. *Klin. Wochenschr.* 6, 2263-7(1927); *Physiol. Abstracts* 13, 249. Rabbits were used and the experiments designed to det. (1) the effect of a single dose and (2) the effect of continued administration of small doses. The effects on blood sugar, glycogen metabolism, and the histology and appearance of the organs (especially liver) were investigated. Hypoglycemia was constantly obtained with single doses of 5 to 6 mg. per kg. With doses of 2 to 3 mg. per kg., hypoglycemia was not often produced. With the higher dose (5 to 6 mg. per kg.) a preliminary rise in blood sugar lasting for a few hours. If the animal was bled when the hypoglycemic state had supervened, practically no glycogen was found in liver and muscles. A deposition of glycogen in the liver was obtained with doses of 2 to 3 mg. per kg. were given to rabbits that had fasted for 4 days, but the doses had no effect on muscle glycogen. Small doses (2 or 3 mg. per kg.) given every day for long periods eventually proved lethal, and the animals lose wt. No other morphological changes in the liver or other organs apart from loss of glycogen were observed in these animals.

H. L. D.

Synthalin. Its action on blood sugar, glycogenesis, experimental diabetes, metabolism, diuresis, temperature, the general condition, and its toxicity in the normal rabbit. H. VAPLA PUENTES, J. A. COSSANO AND P. RINIS. *Rev. med. Argentina* 40, 409-49(1927); *Physiol. Abstracts* 13, 172; cf. C. A. 22, 1, 1684.—The action of synthalin on the blood sugar is irregular; given by mouth it produces hypoglycemia, by mouth hyperglycemia. The total blood N. increased without any relation to the dose; amino acids also increase with large doses. Large

same time as synthalin do not cause glucosuria. Hypo-spiratory rhythm, polyuria, tonic and clonic convulsions, of synthalin; the liver is much congested and fatty.

H. L. D.

ected into the portal vein. B. VARELA FUENTES, J. A. *Rev. asoc. med. Argentina* 40, 613-30(1927); *Physiol.* [23, 1924.—While insulin is destroyed by the action of the ected. Injection of synthalin into the portal vein is sugar and in total non-protein N; occasionally by an of the blood.

surgical anesthesia. R. I. MACKAY AND S. C. DYKE. [1; *Squibb Abstr. Bull.* 2A, 66.—The chloride content of the while that of the whole blood remains const., there the red cells to the plasma. The fixed Cl_2 of the plasma but the fall tends to become slower and to cease altogether Meanwhile the blood sugar rises quickly at first, becoming by reaching the original level. No apparent relationship duration of the variation of the chlorides and the fixed [1 hand, and of the sugar content of the blood on the other.

C. R. F.

cer. G. LOEWY AND J. LOISELEUR. *Bull. Cancer* 549, 1. 2A, 182-3.—Glycogen was used as a vehicle for colloidal ly. The authors claim no clear case of cure, but believe in the very great general improvement observed in some

C. R. F.

Toxicity studies of colloidal gold. G. E. JORGENSEN. *Clin. Med. & Surg.* 36, 38(1929); *Squibb Abstr. Bull.* 2A, 52.—A colloidal Au contg. traces of K aurate and AuCl_3 was tolerated neither by rabbits nor mice. Semi-weekly intravenous injections of 1.5 cc. of pure colloidal Au (Colladaurum) in a rabbit with carcinoma of the mammary gland presented no ill effects; furthermore, after 16 weeks' therapy the carcinoma growth had been reduced in size and consisted of much connective tissue that had replaced the gland tissue, while the remaining traces of true carcinomatous tissue indicated total obliteration of the lumen of all ducts; no metastasis was observed in the animal. The danger of contaminated colloidal Au preps. as well as the harmlessness of pure preps. even when administered in enormous doses is made apparent by these studies.

C. R. F.

Tropine and atropine. RAYMOND HAMET. *Compt. rend.* 188, 820-2(1929).—A pharmacol. test using a dog anesthetized with chloralose, with the intestine *in situ*, showed that tropine acts diametrically opposite to atropine; in fact, tropine increases tonus while atropine decreases it.

C. R. F.

Clinical application of urinary antiseptics. H. W. E. WALTHOUR. *Southern Med. J.* 32, 161(1929); *Squibb Abstr. Bull.* 2A, 138.—Mercurochrome and neutral acriflavine are effective, but not widely applicable because of the unpleasant side-effects produced, since the desired effect was not produced with hexylresorcinol within 10 days. Pyridium acts upon bacteriuria promptly and effectively. Whereas bacilli and cocci are retarded from the very first dose of the drug, it is in gonococcal infections that pyridium seems to have a real selective action. In acute gonorrhea, it is a most valued adjunct and proved effective. The av. dose of pyridium (condensation product of α - and β -isomers of phenylazo- α, α -diaminopyridine-HCl) per day is 0.6 g. The drug is contra-indicated in severe hepatitis, and chronic parenchymatous nephritis.

C. R. F.

The influence of ergotamine on blood-sugar concentration. L. RIGÓ AND L. VESZELSZKY. *Péter Univ. Hungarian Medical Archiv* 29, 517-9(1928).—Subcutaneous injection of small doses of ergotamine (0.5-1.0 mg. per kg.) into fasting rabbits caused transient hypoglycemia. Larger doses (2-5 mg.) caused hyperglycemia. The results agree with the observations of Lang, Vas and Rigo on the action of parasympathetic poisons on blood sugar (*C. A.* 22, 1625)

G. H. v. F.

Action of album salivum on smooth muscle. G. LIO AND R. AGNOLI. *Arch.*

intern. pharmacodynamic 33, 400-8(1927); *Physiol. Abstracts* 18, 100-101(1927).—Cause increase and then diminish the tone of smooth muscle. In weaker joints cause increase of irritability without the atonic effect. The lowering of tone is probably a factor in the hypotensive action of garlic.

The therapeutic activity of liquid preparations of ergot on the Calcutta General Hospital. R. N. CHOPRA AND PREMANKOR DE. School of Tropical Medicine, Calcutta. *Indian Med. Gaz.* 63, 519-21(1928).

A case of auricular fibrillation after aspirin. A. K. DUTT GUPTA. Calcutta General Hospital. *Indian Med. Gaz.* 63, 531-2(1928).

Quinine intolerance. BINODE KRISHNA BANERJI. Calcutta General Hospital. *Indian Med. Gaz.* 63, 533(1928).

The successful treatment of vitiligo diffusa by injections of arsenic. MOHAMMED ABDUL QUIYUM. District Board, Durhanga. *Indian Med. Gaz.* 63, 582(1928).—A case history.

Berberine in the treatment of oriental boil. B. M. DAS GUPTA. School of Tropical Med. and Hyg., Calcutta. *Indian Med. Gaz.* 63, 577-78(1928).

Berberine sulfate inhibits the growth of *Leishmania tropica* even in high dilns. like 1 in 80,000. Stibosan has no local action on the parasite. This may account for the fact that Sb ointments are useless in the treatment of oriental boil. Berberine sulfate given by infiltrating the tissues around the edge of a sore brings about complete cure in 2 or 3 weeks. This drug promises to be a specific cure for the affection.

Intravenous calcium therapy. S. RAMA IYER. *Indian Med. Gaz.* 63, 77-8(1929).—Favorable action in gonorrheal orchitis is reported.

The behavior of easily removable blood iron toward carbon monoxide, oxygen and hydrocyanic acid. GEORG BARKAN AND EVA BERGER. *Klin. Wochschr.* 7, 1868(1928); cf. following abstract. Preliminary report.

Differentiation of the readily separable iron of the blood upon the basis of its reactions with carbon monoxide and oxygen. GEORG BARKAN AND EVA BERGER. Univ. Frankfurt a. M. *Arch. expul. Path. Pharmacol.* 136, 278-99(1928); cf. preceding abstract.—A portion (about 65%) of the readily dissociable Fe from the blood reacts reversibly with CO and O_2 . Satn. with CO or removal of the dissociable Fe completely prevents the sepn. of this portion by means of acid. A smaller portion of the Fe (about 35%) does not react with O_2 and CO, at least when under atm. pressure, and in this fraction is to be found the acid-sol. Fe of the serum and plasma. HCN is without effect on this readily separable Fe. CO has also an effect in the living person, and the changes induced can be observed in CO intoxication earlier and in convalescence longer than can CO hemoglobin.

Hypertension after tetrahydronaphthylamine and blood leucocytes. G. ROSENOW. *Klin. Wochschr.* 8, 24(1929).—Administration of tetrahydronaphthylamine leads to a marked rise in body temp., but the leucocyte count remains unchanged.

The biological action of the active iron preparation, Siderac. L. FRESNIUS AND K. HARPUDE. *Klin. Wochschr.* 8, 69-71(1929). The administration of Siderac has no effect upon the C/N quotient in the urine. This is contrary to the findings of Goldbloom (*Z. expul. Med.* 59, 514(1928), cf. *C. A.* 22, 4649). The reasons for the discrepancy are discussed in detail.

The acute and chronic action of morphine. E. GRUNTHAL AND P. HOEFER. *Klin. Wochschr.* 8, 104-7(1929).—Morphine acts acutely by reducing the sensitiveness of the skin to pressure and pain; but it has no effect upon the sensitiveness of the skin to temp. changes. The repeated administration of morphine leads to a tolerance of the pain centers to this drug, thus making it necessary to give larger doses to produce the previous degree of desensitization. The pressure and temp. centers do not acquire a tolerance.

The behavior of iodine in the body fluids after the oral administration of iodides and of iodized protein. GEORG BARKAN AND WILHELM LEISTNER. *Klin. Wochschr.* 8, 117-8(1929).—Iodide is detd. in 2 forms, namely: inorg., that pptd. by Ag in HNO₃ soln. and org., that which is not pptd. under these conditions. Administration of inorg. I never leads to the appearance of org. I in the blood or in the urine. The oral administration of iodized protein leads to the appearance of org. I in the blood and in the urine. The concn. in the urine is higher than that in the blood. Org. I is not excreted into the stomach or into the saliva.

Cobalt and blood. KLARA WALTNER AND KARL WALTNER. Biol. Inst. Tibury and Univ. Kinderklinik Szeged. *Klin. Wochschr.* 8, 313(1929).—Administration of a diet contg. 2% of metallic Co to white rats leads to a 20-25% elevation in the erythrocyte count and hemoglobin value. The metal is quite toxic. The animals do not grow.

for 5-6 weeks. Animals can be kept alive for 6-7 months on a diet contg. Co. The animals grow normally, but lose their fertility. The erythrocytes increased to over 10 million and the hemoglobin to 165%. The hemoglobin and erythrocytes can be increased 20% in 24 hrs. by a single injection of 0.1 g. $\text{Co}(\text{NO}_3)_3$.

MILTON HANKE

Use of chewing gum as an oral disinfectant. WOLFGANG WEICHARDT. *Klin. Wochschr.* 8, 861(1929).—Chewing gum was mixed with Silargel (a colloidal AgCl prepn.). Chewing for 2.5 hrs. reduces the bacterial flora of the mouth by about one half. The prepn. appears to be particularly effective against hemolytic streptococci.

MILTON HANKE

Experimental studies with gold preparations. WOLFGANG HEUBNER. *Klin. Wochschr.* 8, 393-5(1929).—Colloidal gold and electropositive gold in complex or simple combination show marked differences in their mode of retention by the animal tissues. Thus Goldprotasin, a colloidal gold prepn., is retained for days. Practically all of the injected Au can be recovered from the liver and spleen, 95% of it being in the liver. A very small amt. is excreted into the gall bladder. The kidneys and lungs contain very little. NaAuCl_4 or Sanoecrysin ($\text{Au}(\text{S}_2\text{O}_4)_2 \cdot \text{Na}_2 \cdot 2\text{H}_2\text{O}$) is excreted into the urine. The largest portion of the injected Au is found in the kidneys. The liver and spleen contain very little Au.

MILTON HANKE

Treatment of morbus basedowii with Neodorm. The action of substances that affect surface tension and can lead to a displacement of hormone. H. W. BANSI AND H. KRETZSCHMAR. *Klin. Wochschr.* 8, 395-7(1929).—Neodorm, α -bromo- α -isopropylbutyramide, markedly reduces the surface tension of water. It is readily adsorbed by charcoal from an aq. soln. Charcoal absorbs some adrenaline from an aq. soln. Much less adrenaline is adsorbed by charcoal from a soln. that also contains Neodorm. Two tablets, 0.6 g. Neodorm, will induce sleep in a normal individual. The same amt. will produce a feeling of restfulness (but will not induce sleep) in patients afflicted with Basedow's disease. The pulse rate remains high in the latter cases. A combination of Neodorm with I (as iodide) leads to a feeling of restfulness, a reduction in the pulse rate and an increase in body wt.

MILTON HANKE

Physiological action of chloralose. R. BARGY AND J. GAUTRELET. *Compt. rend. soc. biol.* 99, 700-5(1928). Chloralose in the normal dog does not modify practically the vago-sympathetic excitability. It causes no change of the blood p_{H} or alk. reserve and no increase of arterial pressure, or of oculo-cardiac reflex. For exptl. anesthesia it is the choice par excellence.

E. H.

Tolerance of uranyl nitrate. MARCEL GARNIER, E. SCHULMANN AND J. MAREK. *Compt. rend. soc. biol.* 99, 707-9(1928); cf. *C. A.* 22, 3703.—By subjecting dogs or rabbits to progressively increasing doses of $\text{UO}_2(\text{NO}_3)_2$ by subcutaneous injection, a tolerance is acquired for doses which would be rapidly fatal if administered for the first time.

E. H.

Cotarnine and some of its quaternary derivatives. C. MLADQVEANU. *Compt. rend. soc. biol.* 99, 742-7(1928).—The toxic actions of the chloromethylate and iodomethylate of cotarnine on dogs, rabbits, mice and frogs are from 2 to 4 times that of cotarnine-HCl. Their actions on the heart, respiration, pupils and neuro-muscular system are generally opposite to that of cotarnine-HCl. The iodomethylate usually exercises a stronger action than the chloromethylate.

E. H.

Mode of action of certain extracts of the anterior lobe of the hypophysis. L. BROUHA AND H. SIMONNET. *Compt. rend. soc. biol.* 99, 750-60(1928).—Certain exts. of the anterior lobe are able to accentuate the phenomenon of ovarian luteinization and of thus causing the arrest of cyclic activity throughout the genital tract. It is probable that the secretion of the anterior lobe has a part in the regulation of the phases of ovarian cyclic activity.

E. H.

Cancerigenic power of coal tar to which has been added certain chemicals. ANDRÉ DE COULON. *Compt. rend. soc. biol.* 99, 805-7(1928).—Expts. were made with rabbits to develop cancers by treatment with coal tar to which one or more of naphthalene, anthracene, carbazole or acridine had been added. It is possible that carbazole added to coal tar promotes the cancerigenic properties of the latter.

E. H.

Action of the lacrymal extract on the spleen and the kidney. D. MICHAEL AND P. VANCEA. *Compt. rend. soc. biol.* 99, 893-4(1928).—The lacrymal ext. caused a contraction of the spleen and kidney by its strong vasoconstrictor action.

E. H.

Action of intravenous injections of bile salts on the rhythm of the normal pulse in man. DUMITRESCO-MANTE AND D. HAGIESCO. *Compt. rend. soc. biol.* 99, 913-4(1928); cf. *C. A.* 22, 3931.—In the 15 cases studied, Na glycocholate in physiol. saline intravenously injected in doses equiv. to 0.2 to 0.5 g. each 5 to 15 mins. had but slight

and transient action on the pulse rhythm, arterial tension (cholate administered the same way showed a transient t. on the cardiac rhythm and arterial tension were slight and

Contraction of the spleen by the injection of adrenaline and blood in animals. A. BORYSIEWICZ. *Compt. rend. soc. biol.* 99, with dogs indicate that the erythrocytes concd. in the spleen & pheric blood by contraction of the organ after the injection crease of erythrocytes in the peripheric blood was noted in remains 40% of neg. results to be explained.

Action of ergotamine on the dog heart. (Ele COELHO. *Compt. rend. soc. biol.* 99, 937-8(1928).—Ergotamine heart in a manner antagonistic to that of adrenaline. It c. of adrenaline on the electrocardiogram, but annuls the dis which are caused by strong doses of adrenaline.

Mechanism of action of ergotamine on the gastric che AND J. CANDIDO DE OLIVEIRA. *Compt. rend. soc. biol.* 99, 22, 3460.—In the majority of cases it appeared that small doses of ergotamine acted as paralyzers and large doses as exciters of the sympathetic. On the vegetative nervous system its action varied according to the dose, the functional state of the organ tested and perhaps the neurotonic constitution of the subject examd. E. H.

Influence of extracts of the suprarenal cortex on frog muscle. J. STRYL. *Compt. rend. soc. biol.* 99, 985-7(1928). Ox suprarenals contain a substance which excites frog muscle and which is easily extd. at an elevated temp. by means of H_2O_2 . The method used insures the destruction of adrenaline without changing the activity of the substance, and at the same time the H_2O_2 preserves the ext. The substance is not affected by boiling except to form a coagulum which disappears on cooling. The action of this substance cannot be attributed to choline as its action is stronger after the removal of choline. The substance suppresses muscular fatigue and increases the contraction of muscles sometimes as much as 100%. E. H.

Action of derivatives of guanidine in diabetes. M. R. CASTEX AND M. SCHREIBGART. *Compt. rend. soc. biol.* 99, 989-1000(1928). A therapeutic study of the action of synthalin and of glukhormet in 23 cases of diabetes showed that these agents had a more favorable action on the glucosuria than on the glucemia in cases of mild or medium diabetes. These drugs increase the tolerance for carbohydrates. In grave cases these drugs are of slight use. In this series of cases synthalin caused gastro-intestinal disturbances when the dose exceeded 20 mg. per day. Such disturbances did not follow the administration of glukhormet. E. H.

Hypoglucemic action of an extract of the pancreas administered per os. S. HORNUNG. *Compt. rend. soc. biol.* 99, 1030(1928). Exts. of cat, dog and calf pancreas were prepd. by grinding the fresh gland and boiling the pulp for 30 mins. in dil. alc. After neutralization with HCl the mass was filtered and the residue was extd. with alc. The alc. and aq. exts. were united and filtered anew and the alc. was removed from the filtrate by evapn. This alc.-aq. ext. administered by mouth in doses of 1.5 to 7.0 g. of the organ per kg. of body wt. caused a lowering of the glucose in cats and dogs in every case. E. H.

Action of glukhormet on the normal dog. S. HORNUNG. *Compt. rend. soc. biol.* 99, 1031(1928); cf. C. A. 22, 1404, 1621.—A comparison of the effects of a prolonged administration of glukhormet with those following a prolonged administration of synthalin showed no appreciable differences between the actions of these medications. E. H.

Toxicity of benzoic and salicylaldehydes in man. J. DADLER. *Compt. rend. soc. biol.* 99, 1038-9(1928).—From a study of 2 cases it is concluded that 40 cc. of salicylaldehyde or 50 to 60 cc. of benzaldehyde by mouth would be followed by death in the human subject in the absence of prompt treatment. E. H.

Influence of ergotamine tartrate, adrenaline and atropine on cerebrospinal fluid pressure. C. I. URUCHIA AND L. DRAGOMIR. *Compt. rend. soc. biol.* 99, 1039-40(1928).—Ergotamine caused a diminution of tension of the cerebrospinal fluid in 8 out of 10 cases of dementia and paralysis and allied conditions. An increase of the tension was observed in 10 similar cases following the injection of adrenaline, while atropine caused an increase in tension in 8 out of 10 similar cases. E. H.

Treatment of chorea by alkalosis. C. I. URUCHIA AND G. POPOVICH. *Compt. rend. soc. biol.* 99, 1072-4(1928).—The administration of adrenaline by injection of ephedrine (racemic synthetic ephedrine) by mouth, assoc. with hyperventilation, gave favorable results in 3 out of 4 cases of chorea. Cardiac complications intervened

one case. During hyperventilation the blood P diminished. were inconst. and less than those of P. E. H.

decrementless theory of propagation of the nerve impulse.

[narcotization and recovery upon the motor nerve. KENICHIRO

id. J. 47, No. 9, Eng. abstr. 2-3(1928).—Isolated nerve was

such that an entire nerve trunk might be made to react

The extinction and recovery times became shorter with repe-

recovery. By "recovery time" is meant the time from the mo-

quired for recovery of the nerve. With Ringer soln. contg. NH_4

to that contg. cocaine, the extinction time was longer than the

chlorethane narcosis, the extinction time and recovery times were

state that the extinction time of one fiber must be much less than

stem. The differential quotient of narcosis, dn/dt , must be considered

as a factor for the theories of decrement and decrementless conduction of nerve

to be applied. X. Changes in the rate of nerve conduction during narcotiza-

MICHIOTOSHI TAMURA. *Ibid* Eng. abstr. 3-4. —Changes in the rate of conduction of nerve impulse during narcotization and recovery were measured. The sciatic-gastrocnemius prepn. of the Japanese toad (*Bufo vulgaris formosus* Baulenger) was used with Ringer soln. modified so as to contain (1) 0.01% NH_4 , (2) 0.2% cocaine and 0.2% NaHCO_3 , (3) 0.2% cocaine and 0.02% NaHCO_3 , (4) 2.5% urethan, (5) 0.14% chlorethane, (6) 2.5% chloral hydrate. The rate of conduction at room temp. was about 20 m. per sec. This rate decreased gradually with narcotization. The minimal rates of conduction for each of the solns. used were (1) 1.12, (2) 1.84, (3) 1.12, (4) 2.5, (5) 0.68, (6) 0.8 m. per sec., resp. Just previous to extinction, the av. rate was 1 m. per sec.

W. D. LANGLEY

The action of adrenaline on blood pressure in relation to the various methods of introduction into the organism. G. CARDONARO. *Boll. soc. ital. sper.* 3, 413-6(1928).—Adrenaline soln. in various concns. was introduced into dogs by the following routes: intravenous, subcutaneous, intramuscular and gastro-enteric (stomach, small intestine, rectum). Adrenaline exerted its usual hypertensive action when introduced directly

into the circulation, even in min. doses (0.001 mg. per kg. The introduction of the drug by other routes in doses 500 times that used intravenously did not show a clear, well-defined, const. hypertension. C. assumes that the drug is either very slowly absorbed, or other factors influence its hypertensive action. The other physiol. effects of adrenaline such as glucosuria, hyperglucemia and toxicity in high doses were always detected regardless of the route of introduction.

PETER MASUCCI

The biological action of thallium acetate. G. TRUFFI. *Boll. soc. ital. biol. sper.* 3, 433-4(1928).—Various animals, rats, guinea pigs, cats, rabbits, etc., were given various doses of Tl acetate (1) by mouth, (2) by the rectal route and (3) by injection. Those receiving the drug by routes (1) and (2) developed diffused depilation with varying intensity; the most intense was in the rat, the least in the guinea pig. Those animals treated by route (3) showed a circumscribed depilation around the point of application. There was no modification of depilatory action by the simultaneous administration of glandular substances. The hypothesis that Tl alopecia is the result of a neuro-endocrine disturbance does not seem tenable. The depilatory action of the metal is exerted directly on the hair follicles.

PETER MASUCCI

Modification of the amino acid curve by the action of thyroxine. EMILIO MARTINI. *Boll. soc. ital. biol. sper.* 3, 451-4(1928).—The effect of thyroid exts. on N metabolism was investigated. The normal amino acid curve on dogs was first established, and then 2 to 1 g. of glycocholi were injected intravenously and its effect on the curve was noted. Conclusions: (a) The amino acid curve was modified by thyroid exts.; the velocity of deamination was accelerated. (b) The action of these exts. is qualitatively and quantitatively comparable to doses of synthetic thyroxine contg. equal quantities of I. (c) A pharmacol. test may be used for standardizing thyroid exts., based on the change in the amino acid curve and this is compared to that of a definite dose of thyroxine. (d) The lipid fractions of the thyroid are inert. (e) Very large doses of thyroxine do not produce a corresponding change in the velocity of deamination.

PETER MASUCCI

Variations in the fibrinogen content of the blood rendered incoagulable by the injection of morphine into the mesenteric veins. A. C. BONGIORNO. *Boll. soc. ital. biol. sper.* 3, 468-70(1928).—The aim of this investigation was to det. whether the fibrinogen content of blood plasma varied after the injection of morphine into the mesenteric veins. To 5 cc. of plasma there was added 150 cc. of an 0.8% soln. of NaCl and 5 cc. of a 2.5% soln. of CaCl_2 . The coagulum was filtered and washed 4 or 5 times

with 0.8% salt soln. and then transferred to a Kjeldahl flask. The plasma rendered incoagulable by morphine did not. By adding 5 cc. of normal serum and then dilg. as above a content of this was also detd. Two samples of blood were artery; one was used to obtain a 0.5% oxalate plasma and serum. The results are given in tabular form. They show phine into the mesenteric veins causes a diminution of fit 46%. This diminution is not sufficient to explain the — for if it depended on the fibrin content alone the diminution The phenomenon is not one of retardation but of a other explanation is given.

The influence of histamine on pancreatic secretion.

Boll. soc. ital. biol. sper. 3, 928-31(1928). Systematic studies were made on the secretion of pancreatic juice under the influence of histamine by using the fistula method. Dogs were anesthetized with chloral and morphine. A temporary fistula was made which impeded the gastric juice produced by the action of insulin from passing into the duodenum and stimulating the formation of secretin. The intravenous injection of 1 cc. of a 0.1% soln. of histamine diluted with 20 cc. Ringer soln. into dogs weighing 15-20 kg. caused the secretion of 1 cc. of pancreatic juice. Successive injections did not give a corresponding amt. of secretion, but a large quantity of gastric juice released by the action of histamine accumulated in the stomach. If 3 cc. of 1% soln. of atropine sulfate was injected a few mins. before 2 cc. of 0.1% histamine soln., only a trace of pancreatic juice was secreted. Under the same conditions, secretin did not lose its power to excite secretion if injected after the histamine, but before the atropine. The tryptic power of pancreatic juice stimulated by histamine when activated with enterokinase was very high and could not be differentiated from the juice stimulated by secretin. Histamine, therefore, undoubtedly excites to a moderate degree pancreatic secretion; this is a distinct property of the substance itself and is not influenced by gastric or biliary secretion.

PETER MASCOTT.

The gastric secretion of histamine studied in dogs operated for "small stomach" according to the Pavlov method. PIETRO MOLINARI TOSATTI. *Boll. soc. ital. biol. sper.* 3, 931-4(1928). A comparative study of gastric secretion was made between that induced by histamine and that by food. A dog with a "small stomach" was used for this purpose. Histamine, when injected subcutaneously in 1-2 mg. doses, excited the secretion of gastric juice from 1 to 1½ hrs. afterward. The fluid was thick and clear with only an occasional speck of mucus. The gastric secretion excited by food was at first very small but later was fairly abundant and lasted 2½-3 hrs. The free HCl content of this juice was at first 0.379% compared to 0.518% in the juice from histamine, but later the acidity and peptic power of the juice equaled that from histamine. The action of histamine on gastric secretion is interpreted by attributing its most characteristic property, that of dilating the capillaries. The histamine stimulus is more intense than the normal stimuli present during the intestinal phase of digestion, but gives rise to a secretion which is comparable to one of those phases. It is possible that normal gastric secretion is caused by some substance similar to histamine or that to histamine itself.

PETER MASCOTT.

Studies on the effect of theophylline on the chloride and water elimination of rabbits with an artificial chronic tubular nephritis. JOHANNES FRANDSEN AND KNUD MØLLER. Univ. Copenhagen. *Acta Med. Scand.* 68, 385-402(1928). A chronic tubular nephritis can be produced in rabbits through repeated injections of small amt. of $K_2Cr_2O_7$. The glomeruli are practically unaffected. Administration of theophylline causes a very great increase in the Cl and H_2O excretion in rabbits with an artificial chronic tubular nephritis, much more so than in normal rabbits. Loading of the tubular animals with NaCl leads to a quicker elimination under the influence of theophylline than in normal animals, whereby also a larger quantity of water is removed.

Insulin, synthalin, glukhorment. A comparative investigation of their influence on the fixation of glucose by cells. EASY B. SALÉN AND T. NYRÉN. I. Med. Eksp. Stockholm. *Acta Med. Scand.* 69, 69-98(1928). In the presence of insulin the fixation of glucose by red blood cells under standard conditions is greatly increased, reaching 180%. The fixation is definitely greater when the glucose is offered in plasma than in 0.9% NaCl. Synthalin and glukhorment show quantitatively the same effect (increase in glucose fixation 149 and 140%, resp.).

S. MOLLER.

The effect of lecithin on the number and the resistance of the red blood cells. ALBERT GRÖNNERÖ AND ANNE LUNDBERG. Hospital Royal, Copenhagen. *Acta Med. Scand.* 69, 99-118(1928).—Lecithin increases the resistance of the red cells to

in vivo. *In vitro* the increased resistance in the presence of the hemolyzing action of saponin and both gave evidence of a rise in the no. of red cells.

S. MORGULIS

The cholesterol content of the blood of normal and AND ISTVAN RECHT. Univ. Budapest. *Biochem.* An injection of histamine causes the cholesterol then this goes back to normal. In splenectomized blood diminishes after similar histamine injections that the histamine produces diametrically opposed red dogs.

S. MORGULIS

ium phosphate on the respiratory metabolism. E. SCHMUTZ-

Univ. Hamburg. *Biochem. Z.* 200, 407-13(1928).—The addn. of Na_2HPO_4 to glucose and meat does not reduce their specific dynamic action. The respiratory quotient rises slower in the first hr. when phosphate is added to glucose, but ultimately reaches the same height as in control expts. The effect of the addn. of 50 g. glucose manifests itself on the respiratory metabolism of the fasting dog in an increase which exceeds by 4.26% the total calories from the sugar. This corresponds to the results found in human subjects (4.25%).

S. MORGULIS

The influence of arsenic and antimony compounds on the enzymic functions of the organism. V. The cause of the inhibitory action of arsenites and arsenates on the salivary amylase. I. A. SMORODINTZEV AND E. A. ILIN. State Univ., Moscow. *Biochem. Z.* 201, 34-47(1928).—Arsenates and arsenites differ sharply in their behavior to buffer solns. In a buffered medium of pH 6.8 Na_2HASO_4 neither accelerates nor inhibits the digestion of starch by salivary amylase. The most acid phosphate-citrate buffer does not diminish the basic reaction of arsenite. K HASO_3 causes a greater shift to the alk. side and has a stronger effect than Na_2HASO_4 . The inhibitory action of salts of quinquevalent As on amylase can be explained by a shift in the pH of the medium to the alk. side of the optimum activity of the enzyme on starch, whereas with trivalent salts the As also exerts its action independent of the change in the active reaction.

S. MORGULIS

The influence of different preparations of the quinine group on the enzymic functions of the organism. X. The influence of quinine on the dynamics of the protein decomposition and of the oxidation-reduction processes. I. A. SMORODINTZEV. State Univ., Moscow. *Biochem. Z.* 201, 66-76(1928).—cf. C. I. 23, 201. The influence of quinine on the organism is detected by analyzing its effect on each enzyme of the plasma. Quinine as a paralyzing poison disturbs the coordination of the enzymic processes of the protoplasm, which at first diminishes the activity and then causes the death of the plasma. The balance between the function of the oxidative and the autolytic enzymes forms one of the most essential regulators of purposeful activity. Quinine paralyzes the oxidative enzymes, whereby the autolytic enzymes gain predominance. A 0.005% quinine soln. inhibits the activity of the blood oxidases and the synthesis of hippuric acid. Following its primary effect upon the balance of enzymic processes, quinine produces the paralyzing effect. Thus, through injury to the tissue oxidases it causes a diminution in the amt. of O_2 consumed and CO_2 produced. The increased protein decompn. leads to a greater N elimination in the urine but is soon followed by diminution in N metabolism. The autolysis of liver is at first increased by small quinine doses (0.001-0.050%); then it becomes slower and ceases altogether. As a result of this, the gaseous and N metabolism are lowered and the heat production is reduced, which explains the antipyretic action of quinine. Antipyrine, unlike quinine, lowers the heat production through its effect on the central nervous system. The diminished elimination of uric acid and of urea under the influence of therapeutic doses of quinine is likewise the result of its direct effect on tissue proteases.

S. MORGULIS

Further studies on the effect of cyanide on the living cell. MICHAEL S. RESNICHENKO. Timirjaseff-Forschungsinst., Moscow. *Biochem. Z.* 201, 110-24(1928).—The respiration of ascaris eggs is partially inhibited by KCN of even high concn. because lipids of the egg membrane make it very poorly permeable to the KCN. On the contrary, HCN represses the oxidative process in the ascaris egg very powerfully. In this respect the ascaris eggs form no exception, other cells showing the same behavior. The semipermeable lipid membrane protects the egg cell from most salts, inorg. acids and bases, but HCN diffuses with great ease and completely represses oxidation. On the contrary, KCN diffuses very poorly and does not attain within the egg cell such concn. as completely to inhibit its oxidation. The difference in permeability between HCN and KCN is also shown by frog skin which is very permeable to the cyanide

at $pH < 5$ but almost entirely impermeable at $pH > 9$. The peculiar ascaris egg membrane to KCN is responsible for the peculiar effect on respiratory activity during the initial stages of the KCN action. Only the min. traces of KCN which enter the cell and through hydrolysis in OH concn. KCN in an acid medium or HCN does not produce asphyxiation. The depression of respiration which occurs later is due to the

Changes in the non-protein nitrogen in the perfusion fluid of isolated organs under the influence of adrenaline and ergotamine. Military Med. Acad., Leningrad. *Zhurnal ekspl. Biol. Med.* 10. On perfusing an isolated organ (ox testicle, dog liver or cat lung) in Ringer-Locke soln., the amt. of non-protein N in the perfusion fluid, adding ergotamine (1:100,000) to the perfusion fluid there is a lowering of the N, frequently however preceded by a rise. On adding adrenaline there is always a considerable increase in the non-protein N of the perfusion fluid. This effect of the adrenaline is removed if ergotamine acts upon the organ first. This action of sympathetic drugs suggests that the sympathetic nervous system exerts an influence on the N metabolism of the tissues. S. MORGULIS

The treatment of diabetes with special reference to accessory forms of treatment. WALTER M. BARTLETT. *Ann. Internal Med.* 2, 334-40(1928).—Diet and insulin are the accepted methods of treatment in diabetes. Synthalin is toxic if the dosage exceeds 50 mg. per day. Dechulin in doses of 0.5 g. for each 10 mg. will decrease its toxicity. The action of myrtillin, blueberry leaf ext., is unsatisfactory and uncertain. Its therapeutic value is difficult to ascertain. JOHN T. MYERS

Krysolgan in the treatment of lupus erythematosus: report on twenty-eight cases. WILLIAM H. GOECKERMAN. Mayo Clinic, Rochester, Minn. *Ann. Internal Med.* 2, 428-34(1928).—Doses of Krysolgan varying considerably in amt. gave satisfactory results in 50% of the 28 cases. Patients vary enormously in sensitiveness, but dangerous complications did not develop in this series. JOHN T. MYERS

Tannic acid treatment of burns. End results in 114 cases compared with 32 cases treated by other methods. FENWICK BEEKMAN. *Arch. Surg.* 18, 981-6(1929). Tannic acid is the most satisfactory method of treatment. It prevents absorption of split protein products. JOHN T. MYERS

Parkinsonian rigidity. A clinical and instrumental study of the effect of stramonium, hyoscine, and other alkaloids. E. ARNOLD CARMICHAEL AND F. H. K. GOODE. St. Bartholomew's Hosp., London. *Quart. J. Med.* 22, 51-64(1928). Tincture of stramonium in large doses lessens the Parkinsonian rigidity and increases the ability to perform fine rapid movements as graphically recorded. It seems to improve the mental condition of the patient. It does not affect the tremor. It is as efficient as hyoscine in large subcutaneous doses, is better than hyoscine by mouth, and can be given over long periods of time. The optimum dosage lies usually between 45 and 60 minims three times a day. Toxic symptoms even from large doses are rarely seen. They may be combated by 1/4 drop of eserine in the eye, and by tincture of jalap. Tincture of stramonium is more efficacious than atropine or l- or d-hyoscyamine. It is palliative, not curative. JOHN T. MYERS

The treatment of certain forms of infantile tetany with atmospheres enriched in oxygen and carbon dioxide. EDITH P. W. MCCREA AND H. S. RAPER. Univ. of Manchester. *Quart. J. Med.* 22, 269-79(1929).—When a case failed to respond to all the methods of treatment, it was exposed to a concn. of 40% O and the expired CO₂ was allowed to accumulate until it reached a concn. of 2 to 3%. All but one of 21 cases improved. In all cases the quantity of NH₄ in the urine dropped and the CO₂ combining power of the blood plasma increased. Increasing the concn. of both O and CO₂ was better than increasing O alone. JOHN T. MYERS

The quinidine treatment of auricular fibrillation. JOHN PARKINSON AND NATHAN CAMPBELL. *Quart. J. Med.* 22, 281-303(1929).—Quinidine is more efficient than digitalis in the treatment of paroxysmal fibrillation whenever the attacks are of sufficient length or frequency as to justify continuous medication, providing the patient is well enough in the intervals. Used thus, it is devoid of risk. It is preferable if the fibrillation is of recent onset, or in the absence of serious failure or much cardiac enlargement. If the fibrillation has continued longer than 6 months, digitalis is better. JOHN T. MYERS

Studies on the toxicity of various lead compounds given intravenously. BISCNOFF, L. C. MAXWELL, RICHARD D. EVANS AND FRANKLIN R. NUZUM. Hospital, Santa Barbara, Calif. *J. Pharmacol.* 34, 85-100(1928).—The Pb compounds studied can be divided into 4 groups according to the effect on erythrocytes. The Pb with

action were the glycerophosphate, the oleate and the palmitate. They were the basic carbonate, the oxychloride and the carbonate were very slightly toxic, while PbS, and the acid phosphate of prep. the Pb compds. are described. C. RIEGEL

[205] in the stabilization of blood in transfusion. O. A. STEPPUNKO. *Trans. Sci. Chem.-Pharm. Inst. (Moscow)* 1928, No. 20,ayer 205" in blood transfusions is recommended in preference for the following reasons: (1) It does not react with Ca or thromboplastin and fibrinogen; (2) it is not toxic in other ways in doses non-coagulability of the blood; (3) the vol. of its aq. soln. is less than one tenth of the vol. of an aq. soln. of Na citrate. *In vivo* a complete hemophilia was obtained in rabbits by an a soln. equiv. to 1.5 g. per kg. No deleterious effects were observed when doses were doubled. A dose of 0.3-0.35 g. per kg. body wt. produced a complete hemophilia in dogs without any toxic effects. Doses of 0.8-1.0 g. per kg. produced a complete hemophilia in some animals. A dose of 1.5 seems to be universally toxic. P. W. SALIT

Re. on the pharmacological action of phenylguanidines. I. CANNAYO. *Arch. farmacol. sper.* 45, 249-79 (1928); cf. C. A. 22, 4642. -C. examined the action of phenylguanidine (I) and diphenylguanidine HN C(NHC₆H₅)₂ (II) in regard to their blood sugar-lowering ability, toxicity and the clinical symptoms produced in dogs, rabbits, guinea pigs and white rats. The animals fasted 24 hrs. previously to the expts. Solns. of the nitrate of I in distd. water and of II in slightly acidulated water were applied intravenously, subcutaneously, intramuscularly or by mouth. From the exptl. data given in detail, C. concludes that I and II have a hypoglycemia-producing action. The toxicity of I is greater than that of guanidine, II is still more toxic than I. The margin between the toxic and fatal dose is small. The fatal dose of I varied between 100 and 400 mg., the amt. depending on the species of animal and the kind of administration employed. For II, the fatal dose lay between 5 and 50 mg. The symptoms exhibited by the animals prove that I and II exert a poisoning action on the nervous centers, the symptoms being more grave in the case of II. Administration of glucose or adrenaline did not bring about recovery in the animals treated with I. As to the animals treated with II, glucose often had a beneficial effect on the symptoms, while the action of adrenaline was uncertain. G. SCHWOCH

Narcotics. I. Cause of the changed action of calcium salts in magnesium narcosis. SHIGEH YAMAWAKI. Univ. Wien. *Arch. exp. Path. Pharmacol.* 136, 1-33 (1928).—Cats deprived of cerebrum can be awakened from Mg narcosis by CaCl₂ provided corpus striatum is intact, but Ca does not exert this action in thalamus animals; and in such animals CaCl₂ seems to intensify the narcosis, just as it augments the effect of paraldehyde, chloral hydrate, veronal and luminal. Thalamus rabbits are rendered quiet and sleepy by CaCl₂ alone. When but a mild degree of narcosis is induced by small doses of paraldehyde, chloral hydrate, veronal, luminal and urethan, Ca injected intravenously destroys the narcosis, but if larger doses of the narcotics are given and a more profound narcosis established the Ca intensifies the effect. Reactions in cats resemble those in rabbits, although in this species Ca salts incompletely remove Mg narcosis. In frogs deprived of the fore brain CaCl₂ does not remove Mg narcosis as it does in the normal frog, nor does it overcome luminal and scopolamine narcosis in these animals. When injected into the fore brain of frogs MgCl₂ in doses of 0.1 to 0.1 mg. causes narcosis, while CaCl₂ injected into the mid brain is active in doses of 0.01 mg., and is without effect when injected into the fore-brain. The effect of Ca on Mg narcosis is apparently due to a motor stimulation of the cerebrum or corpus striatum. G. H. S.

Influence of functional narcosis and of mechanical exclusion of the brain upon the capillaries of the lung. HERMANN STERNBERG AND MAUREN TAMARI. Univ. Wien. *Arch. exp. Path. Pharmacol.* 136, 34-42 (1928).—Even in deep narcosis the capillaries of the lung remain patent, permitting the passage of ink, and such animals can withstand the injection of relatively large amts. of ink. Animals which are but slightly narcotized or normal animals die from suffocation when ink is injected, the lungs presenting a more intense and more diffuse staining with the entire arterial vascular system of the lung filled with the ink. The alveolar capillaries are free of ink and the pulmonary capillaries are for the most part occluded. Guinea pigs from which the cerebrum has been extirpated behave as do normal animals when given ink injections, but when the mid-brain is removed they react as do animals under deep narcosis. These

observations suggest that reflexes originating in the mid-brain medulla contract the capillaries of the lung.

Mode of action of hypophysin on water and chloride narcosis on the excretion of sodium chloride induced by hy Univ. Wien. *Arch. expil. Path. Pharmacol.* 136, 43-51(1928).—chlorotone causes an inhibition of both water and NaCl di markedly augments the excretion of NaCl and secondarily excretion. In some instances luminal inhibits the water output, effect, but in general NaCl excretion is somewhat increased. in conjunction with hypophysin the water excretion is inhibit both relative and abs. is increased. Paraldehyde and hy cause at times a reduced water output or have no effect, but in tion of NaCl is strongly increased. II. *Ibid* 52-62. The effect of diuresis is detd., in part at least, by the amt. of water present in the large amts. of water are given hypophysin causes a marked in spontaneous diuresis is unchanged or but slightly increased. In diuresis does not depend upon an interference with the transfer of water to tion, but is apparently due to the fact that large amts. of water lead to an increased irritability of the water center and that only under such conditions does the effect of hypophysin become manifest. III. Mechanism of the effect of hypophysin upon the excretion of chlorides. *Ibid* 63-71. In rabbits deprived of kidney the subcutaneous injection of hypophysin causes an increased NaCl concn in the blood. This persists for several hrs. When water is given along with the hypophysin the hydremia masks the increased NaCl. With the increased blood NaCl there occurs after injections of hypophysin an hydremia, even though water is not given, explaining perhaps the increase in spontaneous diuresis caused by hypophysin alone. Obviously the point of attack of hypophysin as regards its effect on NaCl excretion is in the tissues.

G. H. S.

Effect of various experimental procedures upon the water exchange in mammalian muscle. A. GLASS. Univ. Wien. *Arch. expil. Path. Pharmacol.* 136, 72-87(1928).

Neither extirpation of the cortex nor the changes induced by ether, chloral hydrate, paraldehyde, chloralose or morphine modify the water exchange of rabbit muscle. Agents such as chlorotone and luminal which act upon the brain stem are effective as is extirpation of the cortex and corpus striatum and destruction of a portion of the thalamus. Preliminary treatment with hypophysin causes a more prompt and more outspoken effect. Adrenaline and ergotamine are without influence. Water absorption by the muscle is increased by section of the sciadic nerve, but section of the spinal cord between the fourth and fifth cervical vertebrae is without effect. Motor nerves exert no essential regulatory function in water exchange. G. H. S.

Effect of damage to the brain stem and to the sympathetic upon pulmonary edema due to adrenaline. A. GLASS. Univ. Wien. *Arch. expil. Path. Pharmacol.* 136, 88-93 (1928). In both normal animals and those deprived of cerebrum the intravenous injection of 2 mg. of adrenaline invariably causes pulmonary edema. That normal animals have an increased resistance and if the corpora quadrigemina is damaged the percentage of animals to survive is increased. Figure injury to the cerebrum, or the thalamus causes no change in resistance but if a like injury is caused to the corpora quadrigemina the tendency to adrenaline intoxication and pulmonary edema is diminished. Unilateral section of the sympathetic prevents pulmonary edema but bilateral section is without effect. G. H. S.

Surviving Purkinje fibers of the cat heart. F. STRASSER. Univ. Wien. *Arch. expil. Path. Pharmacol.* 136, 101-12(1928). As indicators of pharmacologic activity surviving Purkinje fibers are very sensitive, particularly to strophanthin. G.

Penetration of narcotics of the barbituric acid and urea types into the central nervous system. O. EHRLSMANN. Univ. Berlin. *Arch. expil. Path. Pharmacol.* 136, 1 (1928). The presence of adaline and of bromural in the central nervous system can be demonstrated, as can that of such agents as veronal, luminal, dial and noctal. Both of the urea derivs. are to be found more particularly in the cerebrum and mid brain. Veronal may also be found in the spinal cord. Interruption of veronal narcosis by caffeine does not influence the retention of veronal in the brain, nor can its excretion be prevented by preliminary treatment with urethan, chloral hydrate, ether, scopolamine. G. H. S.

Production from histidine by means of ultra-violet irradiation of a substance which stimulates the intestine and causes a fall in blood pressure. FRIEDRICH LUTINGER. Univ. Berlin. *Arch. expil. Path. Pharmacol.* 136, 129-57(1928).—When exposed to ultra-

1% soln. of histidine-HCl yields a substance which acts like histamine upon the intestine and in inducing a fall in blood pressure. Only about 1% of the histidine is thus transformed and the substance produced can be isolated by means of the isolation of histamine. Within limits the transformation of histidine to histamine is not with an excessive acidity the change does not occur. The effect of irradiation is also, within limitations, not a detg. factor. Substances such as eosine and FeCl_3 do not increase the yield, but by means of irradiation it can be shown that wave length has an important influence upon the transformation. Irradiation of serum failed definitely to increase the quantity of histamine-like substances present, but exts. prepd. from irradiated skin areas in which histamine showed a greater activity than did exts. from normal skin. G. H. S.

Mechanism of the action of thymophysin: Intensifying the action of hormones. E. KRAUS-FAUSTOVA, Univ. Wien. *Arch. exp. Path. Pharmacol.* 136, 158-71 (1928).--Thymus ext. added to a dose of hypophysis ext. which is in itself inert causes an inhibition of the action of a degree comparable to that normally induced by 3 or 4 times as large a dose of hypophysis. A like effect is not exhibited by exts. of mammary glands, ovary, placenta, adrenal and parathyroid, but exts. from muscle influence the effect of hypophysis as does thymus ext. Apparently the effectiveness of the exts. depends in large part on their content in protein and protein-split products. Peptone is effective. G. H. S.

Two members of the adrenaline group, β -hydroxyphenylethanolmethylamine and its ketone. O. KRAMER and G. MALOFF, Univ. Berlin. *Arch. exp. Path. Pharmacol.* 136, 197-207 (1928).--In its physiol. effects upon blood pressure, the heart, intestine and uterus β -hydroxyphenylethanolmethylamine closely resembles adrenaline, while its ketone exhibits some of the attributes of adrenaline, causing mydriasis and hyperglucemia, but causing a reduced blood pressure. The type of reaction following administration of the ketone is somewhat dependent upon the dosage. Upon isolated intestine high concns. of the ketone cause effects like those of adrenaline; low concns. do not. G. H. S.

Anti-insulin and pancreatic secretion. ROBERT MEYER BISCH, DOROTHEE BOCK and WILLI WOHLKENBERG, Univ. Göttingen. *Arch. exp. Path. Pharmacol.* 136, 185-202 (1928).--When human pancreatic juice is subjected to ultra-filtration and injected intravenously into rabbits the immediate effect is an increase in blood pressure followed by the development of toxic symptoms. The pancreatic juice from dogs is less toxic and also has less effect upon the blood pressure. The influence of the exts. is somewhat related to the diet upon which the injected animal has been kept, since weakly active diets cause an elevated blood pressure only in animals which have been upon a diet yielding an acid metabolism. The active substance functions as an anti-insulin, and also is effective in increasing the protein content of the lymph and in reducing its alk. reserve and sugar content. Apparently both insulin and anti-insulin are to be found admixed in pancreatic juice. G. H. S.

Study of coramine. HEINZ KOHLHOFF, Univ. Leipzig. *Arch. exp. Path. Pharmacol.* 136, 331-48 (1928). In rabbits coramine causes a purely stimulating effect as regards the position and labyrinthine reflexes, and the respiration is both deepened and accelerated. After subcutaneous injection or oral administration the effects of coramine become quickly evident, but some 5 to 6 times as much must be given by these routes as is effective after intravenous injection. Absorption takes place from the stomach. The convulsions assoc. with the administration of coramine develop not only in the intact animal but also in those deprived of cerebrum and mid-brain. Deep narcosis induced by chloral hydrate or paraldehyde is not overcome by coramine, but in a slight narcosis the antagonistic effect is exhibited. G. H. S.

Total metabolism and the specific dynamic action of protein in nephrectomized dogs. FR. STRAUSS, Univ. Würzburg. *Arch. exp. Path. Pharmacol.* 136, 349-59 (1928).--The removal of the kidney function interferes with the increase in metabolic activity assoc. with protein administration. G. H. S.

Regulation of insulin production. III. Effects of anhydro-carbohydrates, sugar derivatives and sugar-split products. E. GRAFF and F. MEYTHALER, Univ. Würzburg. *Arch. exp. Path. Pharmacol.* 136, 300-9 (1928); cf. C. A. 22, 4159. --Injections of the substances under test, such as salabrom, glucosamine, sorbite and glyceraldehyde, were given into both the femoral and pancreaticoduodenal arteries. The effects, as measured by the values for blood sugar indicated that some of these substances favor the production of insulin. G. H. S.

Changes induced by ergotamine and adrenaline in the amount of residual nitrogen

in the effluent of isolated organs. G. A. MEDNICKIANZ. *Arch. exptl. Path. Pharmacol.* 136, 370-80(1928).—When an isolated organ the amt. of residual N in the effluent; adrenaline is added to the perfusion fluid the residual N; ergotamine incorporated in the fluid a reduction in the N; this loss is followed by increased amts. The characte. obtained when the organ has been previously perfused.

Toxicological study of coal-tar dyes. II. Their intestinal canal of rabbit and their relation to the Kyoto Imp. Univ. *Kyoto J. Med.* 25, 530-8(1928).—study of 60 coal-tar dyes used in foods, and also of 9 white poisonous, and their influence upon the isolated int. toxicity of these substances is auramine, methyl violet, rhodamine, metanil yellow, orange II, Martins yellow; speaking, the toxic action is greater in basic coloring in definite relation between the chemical constitution and t. nized. III. Their influence upon the isolated heart of upon respiration. *Ibid* 620-33.—The order of the toxic brilliant green, orange II, safranin, methyl violet B, rh Bismarck brown; generally speaking, basic coloring matte acidic, but the orange II belonging to the acidic group w action upon the isolated intestinal canal of a mouse or strongly toxic in its action upon the heart. Those whic blood pressure of a rabbit are: brilliant green, auramine, methyl violet B, Martins yellow, metanil yellow and Bism basic coloring matters are more strongly toxic than

The perfusion of organs with diacetoneglucose in co acidosis and of insulin. J. H. M. A. MARTENS. *Arch.* (1927).—Blood contg. diacetoneglucose or acetone and the liver, kidney, lung, muscles and bones of the extre of the ox and calf. The free and combined acetone co was detd. before and after perfusion by the Messinger-Huppert method. A con tion of acetone and glucose was not detected under the influence of insulin; acetoneglucose was not destroyed by the organs examd. About half of the injected in the form of di- or monoacetoneglucose can be recovered from the air and urine in dogs and rabbits.

The action and biologic assay of ephedrine. PAUL S. PITTENGER. Sher Dohme. *J. Am. Pharm. Assoc.* 17, 634-40(1928). Ephedrine and adrenalin similar in chem. constitution and qual. physiol. effect. Quant. effects are detd. Ephedrine is much less powerful than adrenalin in raising blood pressure, but effect is sustained much longer. Ephedrine acts through oral administration, ad line is destroyed. P's expts indicate that the rise in blood pressure by oral ministration of ephedrine is 4.5-12 times greater than has been previously rep. Ephedrine solns. are stable in light and air. Under these conditions ad solns. decomp. rapidly. No satisfactory biologic assay for ephedrine is known.

Experimental study of the action of a small quantity of iodine administered by stomach. M. MINOWADA. Imp. Univ., Kyoto. *Acta Dermatol.* 11, 191-203. *Ber. ges. Physiol. exptl. Pharmacol.* 46, 807. —Daily for 50-75 days, doves received cc. 0.1% KI soln. The birds were then killed and the organs examd. macro- and microscopically. The thyroid showed a small but definite increase in wt. The blood vessels were not dilated, but the follicles were filled with a thick colloid fluid, the epithelial layer was thinner than usual; briefly, there were signs of a colloid struma, but that the organ from the functional standpoint was in a state of depression. In the spleen the follicles and the reticulo-endothelial cells showed an increase. The vessels of the ovaries were hyperemic. The tubules of the testicles were dilated. Signs of maturity of spermatozoa appeared everywhere; both sex glands were in condition of heightened activity. The liver, pancreas and heart showed no histologic changes, but were heavier than normal.

The combined application of insulin with other different spasmodics or narcotics. ICHISUKU ISHIGAMI. Univ. Kyoto. *Folia pharmacol.* 6, 403-14(1928). *Physiol. exptl. Pharmacol.* 46, 610.—The convulsant action of hexetone, barbituric acid is uninfluenced by insulin, while that of strychnine and picrotoxin is considerably increased. Guanidine is synergistic with insulin, while caffeine is antagonistic.

Narcotics, such as urethan, chloral hydrate and NaBr spasm.

R. C. WILLSON

line on the vagus. KIKUO OGIU. Univ. Kyoto. *Folia pharmacol. japon.* 6, 455-65(1928); *Ber. ges. Physiol. exptl. Pharmacol.* 46, 508.—

Adrenaline on the vagal endings can be detd. in many different al section adrenaline slows the pulse; this effect is removed ed rabbit intestine there is an increased sensitivity to acetyl- st dose of adrenaline.

iting action of "rhizoma, polygonati." PIUNGKI MIN.

acol. japon. 6, 466-78(1928); *Ber. ges. Physiol. exptl. Phar-*

macol. 46, 839.—The action of the alcoholic extract of "rhizoma polygonati" on the blood sugar of the rabbit was studied. This substance at first increases and later decreases the blood sugar. The increase probably has its origin in the carbohydrates of the ext. It also checks adrenaline hyperglucemia and this action is much stronger than the same action of Chosen-ginseng for which "rhizoma polygonati" is a substitute. The latter has no influence on the hyperglucemia produced by NH_4Cl .

R. C. W.

The action of pituitrin on the isolated frog heart. ICHISUKE ISHIGAMI. Univ. Kyoto. *Folia pharmacol. japon.* 6, 415-22(1928); *Ber. ges. Physiol. exptl. Pharmacol.* 46, 509.—Pituitrin is always inhibiting and never stimulating to the isolated heart and strips of heart. This action is uninfluenced by atropine. Adrenaline shows its own action even during the action of pituitrin. Ba is antagonistic to pituitrin. Pituitrin reduces considerably the elec. irritability of the chloralized frog heart. It is indicated that the inhibiting action of pituitrin has nothing to do with the sympatheticus or the parasympathicus, but is concerned only with the muscle itself. Administration of Ca or K exerts no influence on the cardiac action.

R. C. WILLSON

The action of yohimbine on the body temperature. MASASHI YAMAUCHI. Univ. Okayama. *Folia pharmacol. japon.* 6, 479-490(1928); *Ber. ges. Physiol. exptl. Pharmacol.* 46, 526; cf. C. A. 23, 1691.—When yohimbine is administered subcutaneously or intravenously into healthy rabbits, the body temp. is reduced by doses which do not show any external effects. Adrenaline subcutaneously in doses of 0.0001-0.002 g. per kg. lowers the body temp. and after a preliminary dose of adrenaline, the action of yohimbine is weak and when used together the action of the two drugs is less than that of each single drug. The action of adrenaline is almost unchanged by a preliminary dose of yohimbine or it is only slightly strengthened. From the results, it seems probable that the temp.-decreasing action of yohimbine and adrenaline depends chiefly on the peripheral sympathetic nervous system and thus causes changes in the cellular metabolism. Furthermore, it is not impossible that yohimbine acts on the tonus of the blood vessels.

R. C. WILLSON

The activity of adrenaline applied intrapulmonarily. FUMIO SETO. Univ. Kyoto. *Folia pharmacol. japon.* 7, 1-10(1928); *Ber. ges. Physiol. exptl. Pharmacol.* 46, 818.—Adrenaline was introduced into the lungs of rabbits by inhalation, by spraying through a tracheal cannula or by intratracheal injection. When administered in these ways the action of adrenaline on the blood pressure is slower and weaker than when it is given intravenously, but at the same time it is much more rapid and stronger than when administered subcutaneously. The greatest height of the blood pressure follows the inhalation administration; the longest duration follows insufflation and the action starts soonest after intratracheal injection.

R. C. WILLSON

The value of different amino-alcohol esters of the aromatic unsaturated carboxylic acids as local anesthetics. I. The amino-alcohol esters of the unsaturated carboxylic acids containing the piperonyl nucleus. KAGAMASA KUWAHATA, AKIRA OCHIAI AND YOSHIIHIDE NUKITA. Univ. Kyoto. *Folia pharmacol. japon.* 7, 11-29(1928); *Ber. ges. Physiol. exptl. Pharmacol.* 46, 812.—The esters studied included piperocaine (piperonylacryl- β -diethylaminoethanol hydrochloride), piperthesine (piperonylacryl- γ -diethylaminopropanol hydrochloride), piperocaine-PJ (piperonylacryl- β -piperidylaminoethanol hydrochloride) and pipecaine (piperinic acid β -diethylaminoethanol hydrochloride). All these substances are practical anesthetics. Pipecaine is as strongly

anesthetizing as cocaine, while its toxicity is the same anesthetizing power is increased by the addn of adren. by heating. The other three substances act more weakly of toxicity in mice are: first accelerated respiration and then clonic spasms and finally cessation of respiration. 7 of the unsaturated carboxylic acids containing the phe (1928); 46, 813.—The esters studied were apocaine (phenol-HCl), apocaine-PJ (phenylacryl- β -diethylaminoethar (phenyldiacryl- β -diethylaminoethanol-HCl). Apocaine powers equal to cocaine with a toxicity comparable to less thermostable than cocaine. The anesthetizing pov slightly changed by heat sterilization. Lethal doses kill

The production of immunity of the rabbit kidney against mercury. OGURI AND EITARO MARUI. Univ. Kyoto. *Folia pharm. Ber. ges. Physiol. exptl. Pharmacol.* 46, 499; cf. C. A. 23, various studies the authors studied whether and how far the the kidneys after HgCl₂ application is different in normal. The Hg elimination in the urine was detd for 24 hrs after the injection of HgCl₂ according to a modification of the Schumacher Jung method. In animals which had received more than 1 injection of HgCl₂ the amt. of Hg eliminated was about 3 times that after the first injection. Since the kidneys of the animals which withstood the HgCl₂ poisoning show considerable resistance against HgCl₂ in spite of a much increased elimination of Hg, the immunity which was suspected in former expts. is confirmed. R. C. WILLSON

The action of morphine. K. ONO. Univ. Fukuoka. *Fukuoka-Ikkadogaku Zasshi* 20, 543-70 (1927); *Ber. ges. Physiol. exptl. Pharmacol.* 46, 520.—The chronic addn of morphine effects a reduction in the respiratory exchange of the mouse, on the basis of a reduction in the activity of the thyroid gland and the sex glands. Agents which are stimulating to the sympathetic nervous system reduce this action of morphine on the respiratory exchange, increase the respiratory exchange and strengthen the action of morphine, while parasympathotropic stimulating drugs do not alter the influence of morphine on the respiratory exchange. Accordingly there is some relation between the action of morphine and the hormones or the "tension" of the vegetative nervous system. The chronic administration of morphine to rabbits accelerates the blood sedimentation reaction. The viscosity is uninfluenced. There appears a decided reduction in the immunization capacity as is shown by the pathol. changes in the spleen, bone marrow and internal secreting organs. R. C. WILLSON

Studies of the urea-secretoary constant after the use of soporifics. GUYARD, FATTOVICH, MAMESSIMO PROVA, ANCONA. *Note riv. psichiatr.* 16, 9-22 (1928); *Ber. ges. Physiol. exptl. Pharmacol.* 46, 719.—The Ambard constant was detd in 66 mental patients and on the following day redetd, after 2-2 cc. somnifen was administered intramuscularly. Several hrs. later, after the passing of the effects of the drug, another detn. was made. In 65% of the cases the Ambard const. was higher than normal, in 21% less. There was no relation between the age or the type of psychosis and the height of the const. During agitation or confusion higher values were found almost regularly, probably on account of a slight azotemia during decreased permeability of the kidney. Before the injection of somnifen the const. ranged from 0.019 to 0.105 and during the effects of the drug from 0.052 to 0.291. Diuresis was increased in 50% of the cases while an oliguria was noted in 39%. After the passing of the influence of the drug the const. was lessened in 71% of the cases, in 24.2% of these cases it was lessened to a value less than the original one. R. C. WILLSON

The action of adrenaline and pituitrin upon the glomerular capillaries and on their diuretic action. MASANORI OKADA. Univ. Okayama. *Okayama-Igakkai Zasshi* 40, 440-6 (1928); *Ber. ges. Physiol. exptl. Pharmacol.* 46, 440.—Frogs were anesthetized and the superficial capillaries of the kidneys examined microscopically under reflected light. When 1:100,000 adrenaline was added there followed a constriction of the glomerular capillaries and a disappearance of many formerly visible glomeruli. Adrenaline 1:10⁴ and weaker solns. caused capillary dilatation and the appearance of new glomeruli. Pituitrin acts basically the same, constricting in high and dilating in low concns. (1:10). A diuretic action of adrenaline and pituitrin is seen in their dilating effect on the capillaries of the glomeruli. R. C. WILLSON

The influence of termine on the blood pressure of the rabbit. TAKATO HAYAKAWA AND TOYOTA YOSHIDA. Univ. Okayama. *Okayama-Igakkai Zasshi* 40, 1-5 (1928)

exptl. Pharmacol. 46, 503.—Subcutaneous injections of (ylamine) do not change blood pressure; intravenous pe a slight increase of short duration, while moderate or ss decrease, followed in about half the cases by a slight s of moderate and larger doses produce the same picture. atropine and section of the cervical vagus have no effect ssure produced by termine. Preliminary treatment with increase of blood pressure after the small dose of termine, ecreasing action of the larger doses. It is concluded that re through termine depends upon neither a central nor a but chiefly upon a stimulation of the sympathetic center; crease is principally dependent upon a peripheral sympa-

poisons on animals kept in a closed chamber. MASAMI *Okayama-Igakki Zasshi* 40, 533-44(1928); *Ber. ges.* 805. The mice which were used in this expt. were kept ch were closed by rubber balloons under const. air pressure. is proportionate to the size of the exptl. chamber. When the re- d with KOH, the duration of life is shortened and the content of as formerly. Accordingly CO₂ can produce an economy doses of morphine reduce the O consumption and increase eficiency. Somewhat larger doses reduce the resistance e accumulation of CO₂ here has a favorable effect. The appears to be able to balance the paralyzing effect of mor- center. Hexetone increases the O consumption and thus e life. When the CO₂ is removed the shortening of life is more pronounced. In suitable doses of alc. with a narcotic effect, duration of life is extended; irritating doses have the opposite effect. Paraldehyde acts similarly to alc.

R. C. WILLSON

The action of bromide salts on the intestines of warm-blooded animals. I. NOLLE. *Univ. Moscow. Russkii Fiziol. Zhurnal* 11, 77-80(1928); *Ber. ges. Physiol. exptl. Pharmacol.* 46, 807. From expts. with the isolated intestine it was concluded that the stimulating and inhibiting action on the neuromuscular app. of the intestine is effected by the cations. By changing the concn. of the electrolyte the neuromuscular app. of the intestine can be stimulated or inhibited. Na and NH₄ salts increase the intestinal peristalsis, while K salts inhibit the spontaneous movements. Sr salts increase the amplitude of the intestinal contractions.

R. C. WILLSON

The influence of natural glucosides on the effects of cocaine. JUNG, Z. *Hals-, Nasen u. Ohrenheilk.* 18, 267-76, 268-70(1928); *Ber. ges. Physiol. exptl. Pharmacol.* 46, 837. J. studied the anesthetic action of a series of glucosides: adonidin, verbenalin, scillaren, peristaltin, arbutin, helletsuren, convallamarin, cymarinn and amygdalin alone and in combination with cocaine. He observed a strong potentiation of adonidin cocaine solns. on the cornea of the rabbit. While cocaine increases the action of adonidin on the heart, adonidin lessens the cramping action of cocaine. Clinical tests of adonidin-cocaine solns. as a surface anesthetic gave very satisfactory results. This soln. is available commercially under the name "adocaine." R. C. W.

The lactic acid in the muscle of the inkfish. AKINEKE MATSUMOTO. *Acta Schol. Med. Univ. Kyoto* 10, 277-80(1928). The lactic acid extd. from fresh inkfish muscle is optically inactive. The amt. of acid is increased by 72 hours autolysis. The occasional occurrence of some activity in the acid from the autolyzate is being investigated.

DAVID DAVIDSON

Lactic acid formation in the Octopus muscle during autolysis. HIRAO KIMURA. *Univ. Kyoto. Acta Schol. Med. Univ. Imp. Kyoto* 11, 187-92(1928). Matsumoto (cf. preceding abstract) had shown that during the autolysis of the cuttlefish muscle the content of MeCH(OH)CO₂H (I) increased and that some of the isolated Zn salts showed distinct dextrorotation. K. investigated the undecided question whether the dextrorotation is due to formation of *l*-MeCH(OH)CO₂H. Fresh muscles of *Octopus* were divided in 5 equal parts. The 1st part was immediately analyzed for I and the

sp. rotation of the isolated and weighed Zn salts was . . . 4 portions were digested with $\text{CHCl}_3\text{-H}_2\text{O}$ at 37° for 2, 4, . . . treated as the 1st portion. In 3 out of 4 expts. the sp. . . while increasing dextrorotation was observed in the 2 or . . . 1 or 2 portions the dextrorotation was smaller than in . . . of the Zn lactate generally increased for the first 4 or 7 . . . The Zn lactate obtained from the autolyzed material . . . and subjected to fractionated crystn., Zn content, wat . . . were detd. in the 3 fractions. It was seen that the Zn . . . l-lactate. Conclusion: During the autolysis, fo . . . occurs. $d\text{-MeCH(OH)CO}_2\text{H}$ is probably decompd., whil . . . No explanation for the strong decrease in dextrorotat

The extractives of surume-ika (*Ommastrephes* . . . *Acta Schol. Med. Univ. Imp. Kioto* 10, 281-4(1928).—Yields in the "histidine fraction" the picrate of a base . . . same m. p. (225°) as octopin picrate (Morizawa, C. A. . . (C 32.1, H 3.6 and N 22.2%) is different.

The increased oxygen consumption of marine . . . pressures—its variation as a function of the intensit . . . FONTAINE. *Compt. rend.* 188, 460-1(1929).—The O . . . *platessa* increases with increasing pressure up to 150 kg. . . the animals die within 20 mins. After the decrease . . . becomes less than normal; there is, thus, a sort of con

Bionomics of the vinegar eelworm. B. G. PETERS. *Analyst* 53, 661-2.—The vinegar eelworm is a free-liv . . . 2 mm. in length and about 0.04 mm. in breadth, whicl . . . in vinegar. In this paper a full summary and review . . . gators are given (with bibliography), and the industrial . . . have been separately discussed. P.'s expts. on the behavior of the eelworm under . . . phys. and chem. stimuli have confirmed previous observations that the worms have . . . little need of O; they can live for many days in paraffin oil and in olive oil. Under . . . completely air-tight conditions (e. g., in an atm. of H) they usually die in about 3 days, . . . though some may remain alive after 2 weeks. The concn. of the worms in infested . . . vinegar varied from about 1000 to 2000 worms per cc. The eelworm tolerates temps . . . between 0° and 35° , can survive for short intervals at -20° , and can live for several . . . days at 37° . It is practically indifferent to light. Both the worm and its larva are . . . susceptible to drying, surviving for only a few mins. after complete evapn. of water in . . . which they were placed. The toleration limits for H-ion concn. are p_H 1.6 on the acid . . . side and about p_H 11 on the alk. side. So far as can be ascertained, the worm tends . . . to make the medium in which it lives slightly but more permanently acid than it would . . . otherwise have been. It is very sensitive to I, NH_3 , and CHCl_3 , but is extraordinarily . . . resistant to most chem. substances, including acidity indicators and buffer solns. It . . . can be grown in most culture media, and has been cultivated aseptically by Zimmer . . . mann, who finds that either bacteria (living or dead) or an unknown substance from . . . the autolyzate of yeast is essential as food. All the evidence goes to show that the . . . worm is non-pathogenic to man. As regards the vinegar industry, it is only demon . . . strably harmful when it occurs in the acetifiers, from which it can be excluded by a . . . suitably high temp. (40°). Nothing is definitely known as to its origin in vinegar, . . . but it has been suggested that it may be conveyed on the legs of the vinegar fly, *Dros . . . phila funebris*, and Henneberg claims that he has demonstrated this mode of trans . . . ference. In former communications (*J. Helminth* 5, 133, 183(1927)), P. has dealt with . . . the nomenclature of the vinegar eelworm and with its anatomy. As genera are already . . . recorded with the names *Anguillina* and *Anguillulina*, a new genus *Turbatrix* is created, . . . comprising: (1) *T. aceti* (Müller, 1783) var. *aceti* (in vinegar); (2) *T. aceti* (Müller, . . . 1783) var. *dryophila* (Leuckart, 1887), de Man, 1910 (in the slime-flux of the oak); . . . (3) *T. Ludwigii* (de Man, 1910) (in the slime-flux of the oak); (4) *T. rediviva* (Linnaeus, . . . 1767) (in sour paste).

Physico-chemical characteristics of the breeding migration fast of (Amur River) . . . Keta salmon. B. P. PENTECOV, YU. N. MENTOV AND E. F. KUMMAEV. *Bull. Pacific . . . Sci. Fishery Research Sta. (Vladivostok)* 2, Pt. 1, 3-64(1928); Russian text with English . . . summary.—Specimens of *Oncorhynchus keta* were obtained at the mouth, along the . . . course and at the sources (spawning grounds) of the Amur River. The spawning . . . grounds were approx. 1200 miles from the sea. The wt. of the head, genital organs, . . . skin and bones of both sexes greatly increased during the spawning migration. The

from 68.65 to 85.73%, or, *vice versa*, the dry matter 14.27%; in females, the H_2O content increased from 66.95 substances decreased from 33.05 to 15.37%. Fat content of 9 to 0.17%, and, of females, from 11.28% to 0.49%, or for 1.22% for males, and from 34.13% to 3.17% for females. l, in males, from 21.08 to 13.26%, and for females, from % protein in the dry matter increased from 67.26% to 92.89% 8% to 90.81% for females. Ash content for males diminished nd for females, from 1.09% to 0.92%, or, for dry matter, the 5 to 5.89% for males, and from 3.29% to 6.02% for females. content (F) in the muscular tissue was parallel to the decrease ter (ΔI) and on the av. $\Delta F = 1.3 \Delta I$. Based on wt. data and several pts. with a body of av. standard size, the reserve of air loss from the sea to the given pt., was detd. It was found time of death at the spawning ground, the loss of fat in males 97.27%, proteins 57.29% in males, and 57.68% in females, and 47.07% in females, H_2O 15.18% in males, and 20.74% in

Males lost 77.21% of their reserves of energy, and females 78.75%. The proportion of the expenditure of the energy of fat to the expenditure of protein energy at first increases, but afterward decreases. On the av. for 1 km. of distance to 1 kg. of the live wt. of the fish, from the first pt., up to the river Hor (1200 km. from the sea) the decrease for males was 505 cal., and, for females, 579 cal. As regards wt. and reserves of energy from the previous pt., the av. of decrease for kg. to km. is 638 cal. for males and 695 for females. The max. expenditure of energy decreases where the current is swiftest. The speed of the fish is in inverse ratio to the speed of the current and both these are, on the av., 115 km. every 24 hrs. The av. daily expenditure of energy in their passage up the river is, for males 25,810 cal., and for females 28,390 cal., for each kg. of live wt. The av. loss of proteins every 24 hrs., up to the Hor, is, for males, 1.734%, and for females, 1.385% of the remaining proteins. The C and N content in the dry, fatless, muscular tissue, from the sea to the time of death, decreases, and the difference between protein content, detd. by difference and by Kjeldahl, increases from 1.09% to 4.63% for males, and 1.21% to 4.02% for females. After the expenditure of $\frac{1}{2}$ of the common reserve of energy (570 km. from the sea) a great change takes place in the proteins, in connection with its greater consumption in relation to fat. This change in the proteins is discovered by the increase of the factor of absorption, *i. e.*, the no. of mg. of methylene blue absorbed by 1 g. of dry flesh from 50 cc. of 0.1% of H_2O soln. The capacity for absorption of the dry muscular tissue contg. fat (factor of absorption $Am.$) increases together with the decrease of fat content (F) in this tissue and with the increase of its H_2O content (W) and $F = W/Am.$ According to the degree of starvation of the salmon the I nos. of fat increase and the sapon. nos. decrease. The degree of change in protein and fat is directly dependent on the expenditure of reserves of energy. The data are collected in 29 tables and 13 figures. A bibliography is appended.

C. R. F.

The resistance of the larvae of the Italian *Anopheles* to the salt content of waters. LIDIA LAFACE. Expt. Sta. Antimalaria Campaign, Rome. *Riv. Malarilogia*. 7, 18-30(1928); English summary 81; *Tropical Disease Bull.* 25, 819.—*Anopheles elutus* in the lab. is more tolerant of NaCl than *A. maculipennis* and the tolerance of *A. superpictus* is intermediate to the two.

C. R. F.

The effect of neurophil drugs on the fiddler crab, *Uca pugnax*. OSCAR W. RICHARDS. Marine Biol. Lab. *Biol. Bull. Marine Biol. Lab.* 56, 28-31(1929).—A reversal of the usual motor responses of the legs of the male fiddler crab has been observed when the animals have been in solns. of picrotoxin, strychnine, phenol pilocarpine, or veratrine in sea water. Camphor increases the irritability of the animals. Atropine, apomorphine, morphine, codeine, caffeine and digitonin are without effect on these crabs. The results of the expts. are discussed in relation to those made with other arthropods.

FREDERICK G. GERMUTH

The carbon dioxide tension of the blood of the snail, *Helix pomatia*, during its annual cycle. MARCEL DUVAL. *Compt. rend.* 188, 104-6(1929).—The CO_2 content of snail blood is const. throughout the year. This constancy maintains an ionic reaction in the blood which is independent of the snail's activity.

ARTHUR GROLLMAN

Action of hydrogen sulfide on the protoplasm of *Amoeba proteus*. FLOYD J. BRINLEY. Battle Creek Coll. *Science* 69, 336(1929); cf. *C. A.* 22, 4179.—The toxicity of H_2S on *Amoebae* is due to its action on the surface membrane. The internal protoplasm of the cell is not injured by H_2S .

ARTHUR GROLLMAN

Metabolism studies on the cold-blooded animal heart. different types of work. G. EISMAYER AND H. QUINCKER. *Z. Biol.* 88, 139-44 (1928).—Just as in warm-blooded animals, the from the nutrient fluid after it has used the reserve material.

Biochemistry of selachians. I. Investigations on the FLÖSSNER AND F. KUTSCHER. *Univ. Marburg. Z. Biol.* was isolated as the picrate ($C_8H_5N_3AgNO_3$, m. 280°) from In the lysine fraction were found choline, purified as the au. m. $244-245^\circ$, slightly sol.), niosin, isolated as neosinaurate (Ca , easily sol.). The mother liquor yielded histidine as the result picrate of which m. 190° . The filtrate from this showed demonstrated in the filtrate from phosphotungstic acid treat. This substance is the same as that isolated by Kutscher and *vulgaris*. It is slightly sol. in cold water, easily sol. in hot wat biuret, tryptophan, ninhydrin and Morner reactions were ne Millons reactions were pos. The m. p. was between 191° and valerician acids were also obtained.

FRANCIS KRASNOW

Chemical composition of the ovaries of Octopus ocellatus. TSUTOMU KAWAI. *Univ. Kyoto. Acta Schol. Med. Univ. Imp. Kyoto* 11, 137-45 (1928).—Fresh, fully developed ovaries (2186 g.) of *Octopus ocellatus* were finely ground and extd. with $EtOH$ and Et_2O . This ext. gave a ppt. with Me_2CO . The ppt. consisted of a diamino-phosphatide with choline as the N-contg. base. The fraction sol. in Me_2CO yielded cholesterol. The dry ovaries (475 g.) remaining as a residue from the $EtOH-Et_2O$ extn. gave almost all protein reactions. They contained 12.52% N, 0.67% P, 1.00% S and 5.70% carbohydrates (as glucose). Two hundred g. of dry ovaries were hydrolyzed with 600 cc. of fuming HCl and analyzed for the constituents of the proteins and nucleoproteins. The following amts. were obtained: 0.19 g. guanine, 1.43 g. adenine, 0.35 g. hypoxanthine, 0.75 g. glycine, 4.23 g. alanine, 0.88 g. valine, 22.32 g. leucine, 0.21 g. isoleucine, 0.24 g. proline, 2.38 g. phenylalanine, 5.86 g. glutamic acid, 3.14 g. aspartic acid, 1.32 g. serine, 1.78 g. tyrosine, 1.60 g. histidine, 5.14 g. arginine, 7.12 g. lysine and 0.72 g. choline. Xanthine and tryptophan were present. G. S.

The influence of some physical-chemical factors of the perfusion liquid on the frog's heart. S. SARGENESSNIKOV. *Univ. Irkutsk. Russk. Zool. Zhurnal* 11, 100-20 (1928); *Ber. ges. Physiol. exper. Pharmacol.* 46, 705. Solutions of different pH values were perfused through the heart by means of an aortic cannula. The pH was determined colorimetrically by the Michaelis method. Fourteen solutions were used the pH ranging from 6.0 to 8.35. The action on the heart was based on the height of contraction produced. The solutions were divided into 3 groups: (1) optimum solutions, pH 7.0-7.6, height of contraction above 20 cm.; (2) contraction 10-20 cm., pH 6.5-6.9; (3) contraction below 10 cm., pH 7.8-8.35 and 6.0-6.1. Stronger concns. both alk. and acid, reduced the amplitude of the contractions. R. C. WILLSON.

12 - FOODS

F. C. BLANCK AND H. A. LEPPER

Supplementary relations among nutritive values of foods. H. C. SHERMAN. *Columbia Univ. Am. Med.* 34, 767-70 (1928).—Review. FRANCIS KRASNOW.

The zinc content of the chief vegetable foods. GABRIEL HERTRAND AND BOE BENZON. *Bull. soc. hyg. aliment.* 16, 457-63 (1928); cf. C. A. 23, 1696. Zn was determined in a large no. of food products on 200-1500-g. samples by the Ca zincate method of B., *Compt. rend.* 115, 939, 1028 (1902); B. and Javillier, *Bull. soc. chim.* [4], 1, 63 (1906); B. and Mokrugats, C. A. 18, 363. With coconut "milk" only 82 g. was available and no Zn was detected. The following results were obtained, expressed in mg. per kg. on the fresh material, on the dry basis and on the ash, resp.: whole mushrooms (*Agar camp. L.*) 2.8, 44.4, 308; whole excellent boletus (*Bolet. ed. Fr.*) 5.1, 36.0, 277; whole edible agaric (*Canth. cib. Fr.*) 12.4, 42.6, 711; agar-agar (*Gelid* and *Grua* spp.) 7.7, 17.4; kernel of *Pinus pinus* 55.5, 59.3, 1329; whole oat seed (*Aven. sat. L.*) 10.0, 22.0, 542; oat straw—, 4.3, 84; whole wheat seed (*Trit. sat. Lamk.*) 10.0, 18.7, 84; — straw—, 21.8, 387; wheat bran 32.4, 38.0, 659; whole corn seed (*Zea mays L.*) 18.0, 20.4, 1385; whole millet seed (*Panic. mil. L.*) 17.0, 19.6, 810; whole barley (*Hord. vulg. L.*) 18.0, 21.2, 737; polished rice seed (*Oryza sat. L.*) 2.5, 2.9, 769; bran 30.0, 33.3, 160; whole rye seed (*Secal. cer. L.*) 12.0, 13.5, 716; rye straw

alum seed (*Sorg. vulg. Pers.*) 12.0, 13.8, 420; whole canary-grass seed dry gramineous hay—, 24.0, 323; stone-free dates (*Phoen. dact. L.*) 31.7, 734; fresh asparagus sprouts (*Asp. off. L.*) 3.2, 51.6, 582; onion 13.8, 100.0, 1915; root-free leeks (*All. porr. L.*) 2.3, 23.8, 235; pine-apple (*Lind.*) 2.6, 19.7, 353; edible portion of bananas (*Musa parad. L.*) 10.0, 10.3, 400; hazelnut kernel with tegument (*Coryl. avell. L.*) 1.9, 4.1, 170; nut kernels with 20.0, 24.2, 1259; whole fresh violet figs (*Pic. car. L.*) 1.2, 8.5, 164; whole hemp-seed 82.8, 90.3, 1280; whole leafstalks (*Beta vulg. L.*) 0.2, 3.6, 16; red beet roots 9.3, 68.9, 283; whole spinach leaves (*Spinac. oler. L.*) 6.2, 120.7, 252; eggplant (*Solan. escul.*) 2.0, 11.3, 286; full-grown red potato tubers 4.0, 13.7, 420; com potato starch 1.0, 1.2, 444; whole tomato fruit (*Lycop. esc. Dun.*) 3.4, 66.6, 511; sweet potato tubers (*Conr. bat. L.*) 2.3, 5.1, 186; aerial portion of endive chicory (*Cichor. end. L.*) 0.4, 7.5, 76; green aerial portion of chicory (*Cichor. end. L.*) 1.9, 22.4, 134; aerial portion of cabbage-lettuce (*Lact. sat. L.*) 4.7, 105.2, 500; aerial portion of Roman lettuce (*Lact. sat. L.*) 1.8, 41.9, 316; aerial portions of dandelion (*Tarax. off. Wigg.*) 9.7, 35.4, 212; salsify root (*Trag. porr. L.*) 2.2, 18.8, 576; whole sunflower seed (*Heliant. ann. L.*) 17.0, 11.4, 215 (there is evidently a misprint, as the Zn content given for the fresh plant is higher than that on the dry basis); whole Jerusalem artichoke tubers (*Heliant. tub. L.*) 2.8, 101.0, 400; aerial portions of lamb's lettuce (*Valerian. ed. Poll.*) 5.4, 74.7, 344; carrot root (*Dauc. car. L.*) 1.0, 8.1, 130; whole cucumber fruit (*Cuc. sat. L.*) 1.6, 43.6, 337; edible portion of melon (*Cuc. mel. L.*) 0.9, 16.2, 183; edible portion of pumpkin (*Cuc. max. L.*) 2.1, 44.4, 438; inner portion of pomegranate (*Punic. gran. L.*) 2.5, 11.9, 410; fleshy pericarp of apricots (*Armen. vulg. Lammk.*) 0.4, 3.3, 46; whole fresh almonds (*Amygd. comm. L.*) 10.0, 10.6, 842; fresh almond pericarp 3.8, 11.4, 344; dried almond kernels 18.5, 21.5, 724; tegument of dried almonds 23.7, 73.6, 1286; dried almond shells 4.2, 5.0, 188; fleshy cherry pericarp (*Ceras. vulg. Mill.*) 1.5, 5.6, 305; strawberries (*Frag. ves. L.*) 0.9, 4.4, 131; whole medlar fruits (*Edon. vulg. Pers.*) 1.9, 7.3, 270; fleshy pericarp of peaches (*Pers. vulg. Mill.*) 0.2, 2.0, 36; edible portion of russet apples (*Malus comm. Poir.*) 0.4, 2.0, 98; edible portion of another variety of apples (not specified) 1.0, 9.2, 632; edible portion of pears (*Pyr. comm. L.*) 1.6, 9.2, 452; fleshy pericarp of plums (*Prun. dom. L.*) 0.3, 2.0, 62; whole peanut seeds (*Arac. hyp. L.*) 16.0, 16.8, 780; seedless carrot (*Cerat. sat. L.*) 6.9, 7.9, 161; whole kidney-bean seeds (*Phas. vulg. L.*) 52.5, 56.4, 1500; whole young green bean pods (*Phas. sp. P.*) 0.8, 8.3, 96; whole lentil seeds (*Fer. lens L.*) 34.5, 28.0, 1140; aerial portions of lucern (*Medic. sat. L.*) 4.0, 14.2, 160; whole pea seeds (*Pis. sat. L.*) 44.5, 48.5, 1620; whole soy seeds (*Soni. hisp. Moench.*) 20.0, 22.6, 615; whole vetch seeds (*Vic. sat. L.*) 23.0, 26.7, 754; whole white grapes (*Vit. vin. L.*) 2.0, 12.9, 444; whole black grapes 1.2, 9.1, 240; almost seedless dry Malaga grapes 2.0, 2.5, 88; juice from lemon slices (*Citr. limon. Russo.*) 1.7, 24.0, 594; pressed lemon peel and residue 3.3, 23.7, 455; seedless mandarin slices (*Citr. aur. Russo.*) 0.8, 7.5, 176; mandarin peel 3.9, 17.5, 323; seedless orange slices (*Citr. aur. Russo.*) 1.7, 12.3, 280; orange peel 5.4, 20.2, 424; whole flax seed (*Lin. sat. L.*) 19.0, 30.0, 531; whole white-headed cabbage (*Brass. al. cap. D. C.*) 1.0, 21.2, 176; white edible portion of cauliflower 2.3, 25.4, 205; cross stems and leaves (*Nast. off. R. Br.*) 5.6, 83.7, 500; turnip root (*Brass. nap. var. D. C.*) 0.8, 18.2, 118; turnip leaves 2.1, 38.3, 154; pink radish roots (*Raph. sat. L.*) 1.6, 22.8, 196; pink radish leaves 4.5, 71.7, 280; Swedish turnip root (*Brass. nap. L.*) 3.0, 28.8, 333. Also in *Bull. soc. chim.* 45, 168-75 (1929).

Numbering of flours. JONAS SPONSTA. (*Chem. Abstr.* 4, 76 (1929) English) (1929).—Individual flour grades cannot be evaluated by means of a numerical system. The fat and ash content as well as the acidity vary in the case of the same grade of flour according to the wheat variety, its age, year of harvesting, etc.; therefore, the only deciding factor for judging the quality of flour is the chem. analysis. J. K.

Application of the bromate differential test in the estimation of baking quality of Canadian hard red spring-wheat flour. RALPH K. LARMOUR AND ALAN G. MACLEOD. *Dept. Chem. Univ. Sask. Saskatoon. Sci. Agr.* 9, 477-90 (1929).—Experimentally

milled flours, aged 3 months, were subjected to the Basic (22, 2007). Because of lack of material, 100 g. loaves were from 11.2 to 17.4% crude protein. The action of KBrO_3 "prover" to increase the loaf vol. was studied. A soln. of 0.0 the dough in such concn. that each loaf contained 0.0005 g. that the KBrO_3 test gives a more accurate est. of the more closely approximates com. practice. The Basic potentialities of flours when submitted to com. usage. Us limited no. of samples indicates that the degree of stimulation the protein content. Some flours show no stimulation or flours exhibit high baking quality by the Basic Standard Test to have been developed to nearly the optimum point. The com. flours belong to this class, but occasionally an uncharacteristics of full development.

Does mercury from disinfectants go into the harvest? ALFRED STOCK and WILHELM SIMMERMAN. *Z. angew. Ch.* Grains or flour obtained from plants whose seeds had been material have been analyzed with a view of detecting Hg in order of magnitude of $1/100,000$ mg. or less were found.

Effectual control of milk supply. JOHN W. S. MCCLE Ontario. *Am. Med.* 34, 792-3(1928).

Milk and medical science. JAMES A. TOBRY *Am. Med.*

Rapid methods for the determination of bacteria in milk. Gemeente lab. stad Gent. *Natuurw. Tijdschr.* 11, 9 14(1929) methods used for the detn. of the acidity in milk. The methods are ties and on the direct counting of the microbes. The Skar method is convenient, since it requires only 15 mins., but it gives results which None of the slower methods is absolutely reliable.

Metals in dairy equipment; metallic corrosion in milk products and its effect on flavor. O. F. HUNZIKER, W. A. CORDEN and B. H. NISSEN. *J. Dairy Science* 12, 140-81(1929). The materials used included 19 different metals, plated metals and alloys used in the form of strips 4 in. long and $1\frac{1}{4}$ in. wide as follows. Al, Cu, Fe, Ni, Sn, Zn, galvanized Fe, tinned Cu (edges bare and tinned), Cu Retm, tinned Fe (edges bare and tinned), Mn-Al alloy (Al plated), Allegheny metal, Ascolay, Enduro, type "A," Mn-Al alloy, Monel metal and Ni-Ag. The action of weak org. and mineral acids, sweet and sour milks and creams as well as the effect on the flavor of the milk products were observed. The liquids consisted of 1% solns. of HCl , H_2SO_4 , AcOH , butyric and lactic acids, and 0.2% solns. of citric acid, and the following milk products: sweet milk, acidophilus milk, butter culture, butter milk, sweet and sour cream, and sour neutralized cream. A numerical alignment according to the relative merit of the different metals used is given.

J. C. JUNKENS

Chemical sterilization of dairy utensils. M. J. PRUCHA. III Agr. Expt. Sta. *Circ.* 332, 1-11(1929); cf. *C. A.* 22, 1414.—Solns. contg. 50-100 p. p. m. of active Cl are recommended for pumping through milk-plant equipment, 70-100 p. p. m. for dipping, and 200 p. p. m. for spraying. The Cl may be derived from Cl gas, hypochlorite compds., or chloramine-T. A 10-sec. contact at warm temps. (not above 50°C) gives most efficient results. Utensils must be absolutely clean and free from all traces of milk, grease, or other dirt to be sterilized. Solns. of Cl compds. should not be re-used on dairy utensils.

C. R. F.

Contaminated water as a source of surface flavor in pasteurized creamery butter. DONALD B. SMYTH. Ontario Agr. Coll., Guelph. *Sci. Agr.* 9, 316-20(1929).—Surface flavor in butter was prevalent in rural creameries especially after prolonged periods of wet weather. Five creameries were inspected. All produced butter of a sewage-like, unclean, or putrefactive odor. The water supplies at all the creameries contained *Pseudomonas fluorescens* in large nos. Sterile butter when inoculated with *P. fluorescens* at 25° for 28 days developed typical surface odor and flavor. Where water supplies contain this organism must be used, pasteurization of the water at 93° for 10 mins. renders it safe for use. Neutralization of the cream to not less than 0.35% acid is recommended.

C. R. F.

The proportion of the citrates of milk incorporated in the curd during cheese making. N. S. GOLANOW. *Trans. Roy. Soc. Can.* 22, Sect. V, 237-42(1928).—The citrates in milk are not held by the curd in any greater proportion than that assocd. with the whey

the very small proportion of citric acid or its decomposition in the ripening of cheese. A. T. CAMERON study of the bacterial content. WILFRED Vancouver. *Sci. Agr.* 9, 346-62(1929).—The total Cheshire cheese was 15 million rod-shaped bacteria. It dropped to 93,000. Numerous bacteria were isolated. C. R. F.

ERMAN JAMES. Manitoba Agr. Coll. Winnipeg. *Sci.* 1.7 million gals. of ice cream were used in Can. in 1928. modification (C. A. 20, 2545) of the Babcock-Gerber and that the fat in 28 samples of com. ice cream varied from 32.7 to 41.7% and the bacteria per g. a pint of ice cream ranged from 9 to 21.2 oz. Four varied from 9.2 to 13.2 oz., while 14 pints dished from the vol. of 14 bricks filled from a machine ranged from C. R. F.

of certain salts on the physical properties of ice cream mixes. J. C. HENING AND A. E. DAHLBERG. *J. Dairy Science* 12, 129-39(1929).—Addn. of Na citrate, K oxalate and Na_2HPO_4 to ice cream before pasteurization and homogenization reduced their viscosity and caused them to whip more easily, while the size of the fat-globule clumps were smaller. There appeared to be a relationship between the size of these clumps and viscosity. Ca lactate increased both, making it more difficult to whip. A natural increase of lactic acid to approx. 0.3% or addn. of lactic or citric acids before pasteurization and homogenization caused slight curdling, great viscosity and difficulty to whip, while the ice creams were hard and crumbly. Oxalic acid added before or after, or citric or lactic acids added after homogenization did not have this effect. The addn. of NaHCO_3 and NaOH to mixes of normal acidity caused lower viscosity and easier whipping, while the addn. of the former as neutralizer produced a better flavored ice cream than other neutralizers. It appears probable that the relative amts. of Na and Ca salts in the ice cream mix made from normal dairy products varies sufficiently to affect the whipping properties. When difficult whipping was encountered, it was uniformly corrected and a less viscous mix resulted by the addn. of 0.1% baking soda prior to pasteurization. J. C. JURRIENS

Vanilla flavors do not freeze out of ice cream. P. S. LUCAS AND A. C. MERRILL. Mich. Agr. Expt. Sta., *Quart. Bull.* 11, 118-20(1929).—In order to test out the popular belief that vanilla exts. freeze out in the process of ice cream manuf., various combinations of Mexican, Bourbon and Tonka beans with and without the addn. of vanillin and coumarin were used. The exts. were added in the usual amts. to ice cream mixes of identical compns., the mixes frozen and held in storage. Samples were withdrawn at intervals up to 3 months and compared with freshly prep'd samples. No diminution in flavor strength after storage was detected. The Mexican beans gave the best flavor followed by a mixt. of Mexican and Bourbon beans. Concd. exts. gave results of equal value to single-strength exts. Volatility tests under controlled conditions showed that complete aeration of vanilla exts. did not affect the strength. Similar results were obtained by melting and refreezing ice cream mixes contg. vanilla exts. C. R. F.

The density of lard. W. HALDEN AND R. KUNZE. Univ. Graz Med. Chem. Inst. *Chem. Umschau Fette, Oele, Wachse Harze* 36, 61 2(1929).—The usual statements in the literature for the density of lard, viz., d_{20}^20 0.931-0.938, are too high; a tabulated collection of available records places the normal d_{20}^20 at 0.915-0.923. P. ESCHER

Fat determination in crude lard. B. TYUTYUNNIKOV. *Oil and Fat Industry (Russia)* 1928, No. 4, 14-5.—Ten g. of the lard was ground with 15 g. of CaSO_4 and extd. with ether in a Soxhlet app. This method was found to be superior to the old one, i. e., the preliminary dehydration of the fat tissue with alc., followed by the ether extn. A. A. BOEHTLINGK

The bactericidal action of smoke (as used in smoke-curing of fish). ERNEST HESS. Fisheries Exptl. Sta., Halifax. *Contributions Can. Biology Fisheries* 4, 27-76(1928). Three strains of bacteria (a staphylococcus, *Proteus vulgaris* and a member of the *Sal. typhimurium* group) were exposed to det. the bactericidal action of smoke under various conditions. Smoke from hard wood, soft wood and mixt. of both showed practically no difference in bactericidal power. Dense smoke showed a higher concn. of disinfecting constituents. The spore forms were very resistant to the smoke. HCHO is a very important disinfecting constituent of smoke. In concn. of 3 or more g. per 100 cu. ft. of air it is as bactericidal as smoke itself. M. H. SOULE

Oysters and possible pollution. J. H. ORROR. *Munic. Eng. Sanit. Record* 82,

99-100(1928).—Oysters are liable to accumulate so much colored green. This interferes little with the oyster's green they could apparently be eaten with impunity by

The acids of fruits. E. K. NELSON. U. S. Dept. Am. Med. 34, 812-5(1928).—The total acidity of most fruits and the degree of ripeness. The relative proportions of the various with the degree of ripeness, variety of climatic and soil conditions are the principal acids, which in moderate quantities are readily oxidiz

Some factors in packing of fruits in wine sirup. H. A. HARNBY AND Res. Lab., Glass Container Assoc., N. Y. Glass Container 8, No. 4, 1 acts J. Am. Vinegar Ind. 8, No. 6, 11-3, 21(1929).—The EtOH wined fruits, packed under U. S. Govt. permit, was 3.75%. The EtOH tributed in both fruit and sirup after 7 days' storage. EtOH in canned has little if any preserving action against spoilage. Analyses show that has been added to canned fruit and the latter given a heat treatment, the yield of EtOH will be recovered from the jar of fruit. There is very little loss of EtOH through the jar seal.

The cold-pack method of preserving berries in the Northwest. H. C. DUBIN U. S. Hort. Field Lab. Wenatchee, Wash. Glass Packer 2, 115-20(1929). The use of sucrose in the ratio of 2 parts of fruit to 1 of sucrose in the cold-pack method of preservation retards yeast and mold development, reduces the danger of fermentation, preserves the color of the fruit and to some extent maintains the characteristic flavor and aroma of the berries. Temps. of -15° to -9° are used for freezing the berries, but storage at the latter temp. is satisfactory. Even at -17° , a 50-gal. bbl. of fruit and sugar (2:1) reached a temp. of 5° only after 36 to 48 hrs. The f. p. of a 2:1 pack of berries and sugar is from -3° to -4° . Numerous tests proved that the characteristics of berries, which are of importance in the manu. of jams, jellies and juices, were not significantly affected by the storage of the fruit in the frozen state.

Apple pectins. ROGER PAUL. Ann. fols. 22, 78-82(1929). A brief review of the compn. and properties of pectic juices, with a discussion of their possible uses in the confectionery industry.

Different forms of pectin and how to handle them in manufacturing. C. P. WILSON, Calif. Fruit Growers' Exchange. Glass Packer 2, 113-4(1929). This is a brief informal discussion. Powd. citrus pectin is standardized and marketed according to its jelly strength, that is, the quantity of sugar which 1 lb. of pectin will carry in the manu. of a jelly contg. 65% of sugar. The dry powder dissolves best if added to the fruit juice before the addn. of acid. In that procedure, the set of the jelly is more rapid. Some samples of pectin set very rapidly, others require 24 hrs., still both are of eq. strength. The factors underlying the set of pectin jellies are not fully known. If ion concn. is but 1 of the influencing factors. POWELL WILLIAMS. Speas Mfg. Co., Kansas City. Ibid. 114. In the manu. of pectin jellies best results are obtained by adding the acid to the container and pouring the jelly over it. Lactic, malic, citric, tartaric and H_2PO_4 acids are suitable acids for use in pectin jellies. Lactic acid produces a slow set in jellies and may be added early in the jelly process. Other acids should be added only after complete concn. has been carried on. Powd. apple pectin dissolves readily if mixed with 7 or 8 times its wt. of sugar, added or sprinkled slowly into cold H₂O and gradually brought to the b. p. with agitation.

A rapid method for detecting saccharin in lemonades. JIKI VONDRÁK. Cukrovar. 47, 323-4(1929).—The method depends upon the difference in sweetening between saccharin and glucose (500:1). Solns. of equal degree of sweetness show difference in density, n and polarization. For the n an immersion or sugar refractometer is used, but the free CO_2 has to be removed by aeration or agitation. The density is detected by making small spheres of a mixt. of "carnauba" wax and asphalt in the ratio 1:1. The balls have a density equal to that of a 6% glucose soln. and are just suspended in this concn. If the sugar is replaced by saccharin, the spheres drop to the bottom; this is an indication of saccharin. Such solns. are sent to the bureau for further analysis for saccharin.

Should cinnamon contain a minimum of 18% alcoholic extract? JOHANNES PRASCHER. Chem. Untersuchungsamte der staatlichen Auslandsfleischbeschauanstelle, Stettin. Z. Untersuch. Lebensm. 56, 474-8(1928).—Analysis of 16 samples of cinnamon and cassia from widely sepd. localities showed EtOH exts. varied from 6.5 to 17.76% the ash content from 2.50 to 10.48% and the sand from 0.23 to 7.02%. Some of the

samples showed gross adulteration. An 18% standard for EtOH ext. is unreasonable.

Cyanide.—Coming from bitter apricot kernels. B. E. READ AND C. T. FENG. *Med. J.*, 151(1927); *Quart. J. Pharm.* 1, 109.—Bitter apricot kernels, a source of essential oil of almonds, are a common cause of poisoning in China. The authors describe various food products made from bitter apricot kernels, and give analyses showing that HCN is present only in traces, which, although sufficient for flavoring purposes, is not dangerous.

W. O. E.

The detection of maltol and salicylic acid in the presence of maltol. THEODOR MEHL AND HELMUT BEITTER. *Deut. Forschungsanstalt für Lebensmittelchemie, München. Z. Untersuch. Lebensm.* 56, 472-4(1928); cf. C. A. 21, 2747.—Maltol is formed in the process of malting roasting barley and certain cereals in the manuf. of roasted malt beverages. It is not present in unmalted cereals. To detect maltol, a mixt. of 10 g. of the finely ground sample (usually a coffee substitute), with 1.5-2 g. of blood charcoal (Merck) and 25 cc. CHCl_3 in a small flask are boiled for a short time, cooled and filtered. The filtrate shows a yellowish tinge. Ten cc. is then shaken in a small separatory funnel with 1-2 cc. of H_2O . After sepn. of the CHCl_3 layer, the latter is filtered into a small centrifuge tube. One cc. of very dil. FeCl_3 (2 drops of a 10% soln. in 20 cc. of H_2O) is added, the mixt. thoroughly shaken and finally sepd. by the centrifuge. The presence of maltol is indicated by the characteristic violet color. This reaction is likewise pos. for salicylic acid; hence to detect the latter the following procedure was carried out: Boil 20 g. of the finely ground sample, 3 g. of blood charcoal and 50 cc. of CHCl_3 for a few min. in a flask, cool and filter. Use 10 cc. of the filtrate for the maltol test as just described. Evap. 10 cc. of the CHCl_3 filtrate on the water bath, using a current of air and without boiling. To the residue add 5 cc. of H_3PO_4 (d. 1.7) and 15 cc. of H_2O . Distil, using a small Liebig condenser, until approx. 15 cc. of the distillate is collected. To this distillate add a few drops of a 5% $\text{Ba}(\text{OH})_2$ soln., transfer to an evap. dish and evap. to dryness on a water bath. To the cooled residue add 10 drops of glacial AcOH and 3 drops of Mandelin's reagent (*Z. anal. Chem.* 23, 235). The presence of salicylic acid in the residue is indicated by an indigo blue color. The test will detect about 0.025 mg. of salicylic acid.

C. R. FELLERS

Barley, cull beans and potatoes as feeds for dairy cattle. C. F. HUFFMAN AND A. C. BALTZER. *Mich. Agr. Expt. Sta., Extension Bull.* 73, 18(1929).—Corn has slightly more total digestible nutrients but less protein than barley. Barley and corn are equal lb. for lb. in the ration of milking cows, growing heifers and calves. Two lb. of ground cull beans are equiv. to 1 lb. of cottonseed meal as a protein supplement in the ration of dairy cattle. Cows may be fed 12-20 lb. of cooked beans per day without ill effects although, for best results, beans should be introduced gradually into the ration. Potatoes are approx. equal lb. for lb. to corn silage as a succulent feed for dairy cows. The butter fat produced from dairy cows fed potatoes tends to be silvy; hence potatoes should be fed with caution and should be accompanied by such feeds as a good legume hay and a concentrate similar to cottonseed meal.

C. R. F.

Chemical composition and the nutritive value of yellow and white oats. F. HONCAMP, W. SCHRAMM AND H. WIKSMANN. *Landwirtschaftl. Versuchsstation Rostock. J. Landw.* 76, 113-27(1928); cf. C. A. 23, 1445.—The higher feeding value of yellow oats depends more particularly on its higher starch equiv. and lower proportion of husk than on its slightly larger content of digestible protein.

E. F. SNYDER

The protein content of grass, chiefly meadow foxtail (*Alopecurus pratensis*), as influenced by frequency of cutting. FRANK T. SHUTT, S. N. HAMILTON AND H. H. SELWYN. *Div. of Chem. Dominion Exptl. Farm, Ottawa, Can. J. Agr. Sci.* 18, 411-20(1928).—Data are presented which show a steadily declining C. of moisture in the grass with the lengthening of the periods between cuttings. Frequency of cutting markedly influences the protein content: the shorter the period of growth, the higher the C. of protein. This is correlated with lower fiber content. The seasonal yield of protein per acre was highest with cutting of the grass every 3 weeks. While grass cut every week and every 2 weeks showed a higher protein concn., the total yield was less. Grass cut for hay, including aftermath, yielded total protein only slightly less than that cut every 3 weeks, because of the high protein concn. of the aftermath. P. R. D.

Comparative tests of certain feeds in rations for pigs. E. A. LIVESAY AND E. C. STILLWELL. *W. Va. Agr. Expt. Sta., Bull.* 213, 3-16(1928).—Yellow corn was found superior to white corn in fattening young pigs. In 2 out of 3 trials the pigs fed white corn developed rickets; there is evidence that vitamin D is present in less quantity in white corn than in yellow corn. The fermentation of corn and wheat middlings for 36-48 hrs. by the use of 1 lb. of yeast to 100 lb. of feed does not increase the rate or the

economy of gains. *Fish meal* is approx. equal to tankage as a supplement to corn, buckwheat middlings and a mineral mixt.

Progress in the utilization of saccharin by-products in 1927. (Günzberg) 10. Piration of sorghum grains (COLEMAN, *et al*) 11D. Detection of butter adulteration by means of benzoic peroxide (BODENDORF) 27. Regulations in the edible industry (PENTRADO) 27. Chemicals in the apiary (HUTSON) 15. Behavior of lactose in milk (DEI GRISOGONO) 11C. Bakery furnaces using mazout (Fr. pat. 32,300) 27. Extraction of oil from livers (Fr. pat. 647,941) 27. Substances which can be activated nourishing properties to foods (Belg. pat. 350,983) 17. Antiseptics preserving foods (Brit. pat. 297,074) 17.

Food preservation. THE SMOKED PRODUCTS CO. Fr. 647,367, Jan. 12, 1928. A food preservative is obtained by mixing salt with the constituents of smoke resulting from the combustion of a suitable material such as hickory wood, the constituent being obtained by elec. pptn. The salt may be placed in a rotating drum in which the constituents of the smoke are pptd.

Sterilizing food products in receptacles by use of water heated by steam. JAM. W. PARCELL (dedicated to the citizens of the U. S.). U. S. 1,708,105, April 9, 1928. app. is described.

Apparatus for mixing dough or other materials. BENJAMIN GOULD. U. S. 1,708,550, April 2. Structural features.

Bread making. ELEKTROCHEMISCHE WERKE MÜNCHEN, DR. ADOLPH PIETZSCH. Co. Fr. 647,550, Jan. 21, 1928. H_2O_2 or addnl. products of H_2O_2 are added to the flour before or during the prepn. of the dough.

Apparatus for pasteurizing milk. HALVOR HOLTE. Fr. 647,772, Jan. 21, 1928.

Apparatus for evaporating milk. THE BORDEN CO. Fr. 647,307, Dec. 22, 1927.

Cream powders. J. E. NYROP. Brit. 297,256, Dec. 14, 1927. In producing powders from emulsions such as cream or from emulsions of fatty substances with skimmed milk, the emulsion is homogenized and spray-dried at a low temp. into a gaseous medium, which is free or nearly free from O_2 and which may contain small particles of fat. A product is obtained which may be added to margarine to give it a vitamin content.

Ice cream containing cocoa butter and chocolate. SAMUEL H. BERCH. U. S. 1,708,252, April 9.

Lactose. JULES P. L. BLIER and EUGÈNE P. VITOUX. Fr. 647,252, June 10, 1927. Lactose is obtained from milk coagulated with rennet or acid by cooling to temp. below 0° , removing the liquid from the frozen mass, bringing the extd. liquor quickly to 0° and recovering the crystals of lactose formed.

Determining butter fat in butter. CHESTER E. GRAY. U. S. 1,708,307, April 9. Moisture is evapd. from a sample of butter; the receptacle and contents are then weighed and a solvent for the butter fat alone such as "petroleum ether" is applied to the sample in the same receptacle in which the evapn. was effected; the butter fat soln. is filtered out and the fat content detd. by difference in wt. A special app. is described, which may be used for the evapn. and extn.

Margarine. ALBERT K. EBERMAN. U. S. 1,707,800, April 2. A warm aq. emulsion is formed of suitable fatty substances; it is stabilized by bringing it into contact with a colder medium such as water, the temp. of which is sufficiently low to solidify it into discrete particles; these are then conveyed in thin layers through a body of relatively warmer medium such as warmer water, the temp. of which is below the m. p. of the solidified emulsion; the warmed particles are then worked into a plastic mass.

Cheese. HERMAN P. KERNEN. U. S. 1,708,099, April 9. A sterile cheese is formed from milk by one continuous process comprising coagulating the milk, forming the curd, artificially developing the requisite acidity in them within a relatively short time, sterilizing while stirring and then cooling. U. S. 1,708,100 specifies coagulating the milk, forming the curds and adding to them about 0.375% of Ca phosphate, 0.375% of Ca lactate and 0.375% of NH_4 citrate, heating to about 55° for about 25 min. while stirring in the presence of an emulsifying agent such as Na citrate and then allowing the product to cool.

Food (similar to macaroni) formed of powdered cheese and ground cereals. L. M. JENNINGS and J. L. HAIN (to Skinner Mfg. Co.). Brit. 297,025, Sept. 12, 1927.

Preserving egg material. HOO PATRICK, LTD., and A. MURDOCH. Brit. 297,462, May 25, 1927. Egg yolks or whites, separately or together, are mixed with a small

- portion of glycerol (0.1-5.5% in case of whites alone and somewhat more with yolks) then evapd. (suitably by spray desiccation) to a condition of substantial dryness. Food comprising dried yeast and peanut butter. BANESVAR DASS (to Ellis Co.). U. S. 1,708,914, April 9.
- Pestis solutions. POMOSIN-WERKE G.M.B.H. Fr. 647,451, Jan. 18, 1928. See 284,273 (C. A. 22, 4671).
- Apparatus for extracting juice from grapes, etc. JACQUES PAUL. Fr. 647,168, 1927.
- Preserving and removing residual poisons from fruits. REGINALD H. ROBINSON and HENRY HARTMAN (to the citizens of the United States). U. S. 1,708,330, April 9. Fruit is treated with aq. solns. of HCl and CH₂O.
- Apparatus for treating fruits with sprays of liquids to neutralize and remove insect residues, etc. AUGUST GUIGNARD, AUGUST BOSSE and JOHN GUIGNARD. B. 1,707,610, April 2. Structural features.
- Cleaning and precooling vegetables for shipment. JOHN W. BELL and THOMAS J. BELL. U. S. 1,708,253, April 9. An app. is described.
- Bait blocks for licking by animals. W. ELLIS. Brit. 297,235, Oct. 26, 1927.
- Mineral substances such as Ca phosphate, which are not sol. in water or animal saliva, are mixed with sol. substances such as salt, sugar, or glucose to serve as a binding agent; they are molded into blocks under pressure. The product may be thinly coated with sugar, salt, wax, or other suitable material.

13—GENERAL INDUSTRIAL CHEMISTRY

HARLAN S. MINER

- Cooperation in science and industry. JOCELYN F. THORPE. *Chemistry & Industry* 48, 281-8(1929). E. H.
- Graphic control in the chemical industry. MICHAEL BORNSTEIN. *Przemysl Chem.* 11, 677-683(1927); cf. C. A. 23, 1180. A. C. Z.
- The legal significance of the industrial hazards for the chemical industry. PAUL REIWALD. *Z. angew. Chem.* 42, 217-9(1929). An analysis of the legal status of the chem. industry with respect to its responsibility for accidents, injury to health and property, etc., with illustrations and citations from German cases. W. C. EBAUGH.
- Conveying of liquids (pumping). M. TAILLEFERRE. *Science ind.* 13, 111-25 (1929).—T. describes in detail various types of app. for the conveyance and pumping of liquids. Emphasis is laid on the conveyance of liquids in the chem. industries, acids in particular. T. offers the following classification of the apparatus involved: A. direct pressure app. I. depth app. (1) emulsion, (2) elevating and (3) ejection app. II. surface or excess pressure app. (1) intermittent, (2) continuous. B. indirect pressure app. I. liquid pistons II. membrane pumps III. separators for inert or acid. gas. C. mech. app. Different types of app. under each heading are described and illustrated. A. J. MONACK.
- The discharge of thin liquid layers in centrifuges. H. V. WARTENBERG and H. PERTZEL. *Chem. Fabrik* 1929, 61-3. Poiseuille's law for flow in small tubes is modified and extended to cover the case of the thin liquid layer left in a centrifuge after discharge of the material in process. Expts. on centrifuging of various oils have confirmed the truth of the equations developed, from which it is possible to calc. the thickness of the layer from the viscosity, d , speed of revolution, and centrifuge radius. The influence of capillarity on the layer thickness is discussed. C. Z. ROSECRANS.
- The utilization of raw materials considered from a chemico-economic standpoint. ALBERT SULZMAN. *Chem. Fabrik* 1929, 109-11, 122-4. The need for men with a broad economic outlook as well as a specialized chem. training in the conduct of industries is emphasized, and the ways in which by-products and end products, waste materials and raw materials may reverse their positions with changed conditions are illustrated by many examples. To facilitate the use of (apparent) waste materials, and at the same time to protect manufacturers from the loss of trade secrets, it is proposed that a central bureau—such as a reputable trade journal—act as neutral intermediary in all transactions involving the procurement and distribution of materials, the history of which is not to be divulged. "Works blindness," or the lack of economic vision or sense of proportion that comes to men who stick too closely to their own specialties, makes it desirable to have surveys and suggestions made by neutral and disinterested parties to insure a technical concourse's keeping out of ruts and operating to best advantage. W. C. EBAUGH.

Generalities on the mechanical preparation of minerals. M. V. CHARRIN. *Sci. ind.* 13, 79-86(1929).—C. gives a detailed review of the subjects of crushing and sifting, classification, and concn. of minerals.

Determination of dust and smoke in the inhaled and exhaled breath of man. DRINDER, R. M. THOMSON AND J. L. FINN. *Zentr. ges. Hyg. Grenz.* 18, 17-8(1928); *Wg. u. Abwasser* 25, 186; cf. *C. A.* 22, 3938.—In order to det. danger limits for injurious (which are inhaled, use was made of freshly prepd. ZnO, diam. of particles 0.4μ , (another kind of ZnO), diam. of particles 0.15μ , and marble-dust, diam. of pa. $0.3-0.6\mu$. Definite quantities of these dusts were liberated in a room which contained besides the subject, an elec.-pptn. app. The subject was equipped with a mask which he inhaled the dusty air. Controls were made without the use of masks; exhaled breath was passed into the elec. pptn. app. Thus the quantity of dust in inhalation and exhalation was detd., and the amt. of dust retained by the subject was calcd. Only slight differences were found among the 3 dusts so far as body burden was concerned. The amt. retained averaged from 5.5 to 9.4% of the total inhaled. There were no significant differences between mouth or nose breathing. C. R. F.

The limitation of the production of smoke and other atmospheric impurities. F. KOUDELÁK. *Paliva a Topeni* 10, 185-91(1929).—A statistical study of the sources of smoke and gases in Prague, a description of the present stage of alleviation, and a review of present-day successful installations for decreasing the production of smoke.

FRANK MARESH

Filter cloth investigations. K. ŠANDERA. *Exp. Inst. C. Sugar Ind. Prague. Listy Cukrovar.* 47, 284-8(1929); cf. *C. A.* 23, 2317.—In studying the effect of pressure upon the edges of cloths which are pressed against the frames, found a loss of strength if projections occurred between the cloth and frame, either as roughness, sediment deposits, or sand. Low pressures (55 kg. per sq. cm.) have an insignificant effect; higher pressures (100-550 kg. per sq. cm.) lower the strength. Unfolded cloths were subjected to 550 kg. per sq. cm. for 10 mins.; the tensile strength of cotton fell 66%; of jute 90%. Cloths which were folded and subjected to 550 kg. per sq. cm. disintegrated under a slight pull; 440 kg. per sq. cm. left only one cloth intact, for 330 kg. per sq. cm. cotton cloths retained 10-20% of their original strength, jute 12.5%. Sand placed between the leaves of the cloths in the press and subjected to 550 kg. per sq. cm. decreased the strength of wet cotton cloths 50-83%, of jute 75-92%, of linen 55%. Linen is very resistant to the crushing action of sand when wet; it does not resist this action when dry. Folding a wet cloth before compression is detrimental; cotton cloths lost 51-88% of their tensile strength, jute and linen 100%—the cloth was sheared at the fold by the pressure. Damp cloths were clamped between two 2 mm. steel wires and placed over a tray of H_2O contg. a normal amt. of CO_2 . After 5 days the tensile strength was detd. The tensile strength decreased 6-28%; in all cases the tear occurred in the region of contact with the steel wire. On soaking the cloths in an alk. medium (CaO soln.), the rusting was retarded, and the decrease in tensile strength was within the exptl. error. The resistance to impact delivered by an automatic hammer (2750 g., dropping 200 mm. was best in cotton cloths; a thicker cloth is more resistant than a thin one. The effect of impact was greatest in used cloths. Artificial incrustation with $CaCO_3$ by impregnating the cotton cloths in a CaO soln. and placing them in an atm. with CO_2 or a soln. with CO_2 , decreased the flow of dust H_2O by 5%; for thick cotton cloths the rate of flow was decreased 50-66%, for liquors 15-26% B \acute{e} ., for thin cloths only 33%. Incrustation has the greatest effect upon jute cloth, decreasing the flow 66-75%; the effect upon linen cotton cloths is the same as for thick cotton ones.

FRANK MARESH

Five cases of lead poisoning occurring on board U. S. S. "Wyoming" during the year 1926. W. W. HARGRAVE. *U. S. Naval Med. Bull.* 26, 1018-24(1928). *Pub. Health Eng. Abstr.* E-785b, 2.—Five Pb-poisoning cases occurred as a result of chipping and handling red-lead paint on board ship in confined, ill-ventilated places. During the period 1913-1927 a total of 299 acute cases of Pb poisoning with 1 death, and 197 chronic cases with 1 death are reported in the U. S. Navy.

Lead poisoning on board the U. S. S. "Seattle." JACOB STEFF. *U. S. Naval Med. Bull.* 26, 1011-7(1928); *Pub. Health Eng. Abs.* E-785b, 1.—Eight members of the crew engaged in extensive chipping and painting operations involving red lead paint developed symptoms of Pb poisoning. Short shifts and the use of portable ventilating sets especially in the double bottoms resulted in an abatement of the outbreak.

C. R. F.

Carbon dioxide refrigerating machines. J. C. GOOSMANN. *Power* 6, 718-9(1928).—The first CO_2 compressor was designed by Windhausen in 1880 and 10 yrs.

a machine of similar design was first made in the U. S. The most successful modern compressor is of the dual type, contg. 2 suction ports for operation with 2 suction pressures. This development has been brought about by the need of *liquid cooling*, which is accomplished by partial evapn. of the liquid in a sep. intermediate receiver. Liquid cooling occurs upon dropping the condenser pressure to that adjusted in the intermediate receiver. The liquid temp. immediately drops to that corresponding with the lower pressure, while the vapor liberated from the liquid due to change in temp. runs directly to the compressor through the high-pressure suction port." Thus, capacity may be increased 60% while a reduction in h. p. per ton up to 20% is possible.

Gas purification. **OBERSCHLESISCHE APPARATE U. EISENWERKE G.M.B.H.** Ger. 471,986, Aug. 13, 1927. The gas is driven through several folds of an endless band filter running over a series of rollers and dipping at the bottom into an absorption liquid.

Cooling gases. **KARL SENSSENBRENNER.** Ger. 472,291, Oct. 27, 1926. Hot gases are cooled by supplying them in turn to the distn. vessel and the evaporator of an absorption refrigerating machine having no compressor between the evaporator and the absorber.

Drying gases. **W. C. HOLMES & CO., LTD.** Fr. 647,888, Jan. 16, 1928. In drying gases, particularly gases obtained by the *distn. of coal*, the removal of liquor for regeneration and return of regenerated liquor is so arranged and so regulated that the variation of the concn. of the liquor being used is negligible.

Absorption of gases by liquids. **L'AZOTE FRANÇAIS.** Fr. 647,108, May 25, 1927. Gases are absorbed by a liquid in a column, each plate of which contains fibrous material such as silicic fibers, etc., kept moist by capillary action.

Gas and gas contact system. **GEORGE F. HURT** (to George F. Hurt Engineering Corp.). U. S. 1,708,179, April 9. In operations such as denitration in H₂SO₄ manuf., gas under pressure is discharged upwardly into a body of liquid so that the latter is projected in drops of larger than entrainable size into a body of the gas overlying the liquid. An app. is described.

Recovering volatile products. **MARIUS BLANC.** Fr. 647,423, Jan. 18, 1928. Volatile products such as obtained in the treatment of cloth, drying varnishes, sizing silk, etc., are recovered by means of an endless band coated with an absorbing substance, which is caused to travel past the surface giving off the volatile products. Cf. C. A. 23, 1515.

Recovery of volatile solvents. **I. G. FARBENIND. A.G.** Fr. 647,038, Jan. 13, 1928. In the recovery of volatile solvents from plastic material, etc., which are passed

in a continuous band through a drying chamber contg. air or inert gas, sep. are provided at the point of entry and exit of the band; in these chambers a gas or air at a pressure higher than atm. and higher than that in the drying chamber is circulating to remove impurities from solids. GEORGES BILLARD-VILAS. *Fr.* 647,23, 1928. Substances such as tapioca are spread on a traveling screen and are removed by flexible vacuum tubes.

Separating solids from gases. SOC. ANON. DES CHEMINÉES LOUIS PRAT & INDUR. *Fr.* 647,494, Jan. 19, 1928. Suspended substances are sep'd. from gases, particularly combustion gases, by the addn. of steam and centrifuging.

Separating carbon tetrachloride and alcohol or other liquid mixtures by use of adsorbents such as silica gel. I. G. FARBENIND. A.-G. *Brit.* 296,301, Aug. 27, 1927. A mixt. contg. CCl_4 84 and EtOH 16% when allowed to trickle through a layer of micro-porous silica gel 40 cm. thick undergoes selective adsorption of the EtOH .

Evaporation of liquids. JAMES A. REAVELL. *Fr.* 647,264, Oct. 17, 1927. Liquids are atomized and dried or sep'd. from solids contained therein by bringing the liquid onto the inner face of a rotating disk or cup, from which it is ejected into a drying chamber.

Treating liquids with gases. I. G. FARBENIND. A.-G. *Fr.* 648,004, Jan. 31, 1928. Liquids to be treated with gases are caused to descend a helical path having a simple or multiple pitch, and the gas is caused to ascend or descend in the tower. Grooves may be made in the spiral path and the direction of rotation of the helix may be changed several times.

Distilling liquids suspended in hot gases. J. PINTSCH A.-G. *Brit.* 297,122, Sept. 16, 1927. An app. is described in which liquids are distd. by direct contact with hot gases; the hot vapors obtained, after sep'n. of condensable constituents, are burned with air in a regenerator, which is used for initially heating the gases.

Distillation. THOMAS E. PERKS. *Fr.* 647,861, Jan. 9, 1928. An app. is described for sepg. miscible liquids by distn. In the app. the liquids are circulated in the interior of a closed vessel and heated progressively during their circulation, a no. of sep. collecting chambers being arranged above the liquids in which the liberated vapors are condensed.

Preparation of sols and their utilization for clarification of hot liquids. R. HENRY. *Belg.* 351,967, July 31, 1928. Starchy liquid is mixed with the chem. agent (nature not specified); the liquid to be clarified is added and the whole is emulsified by passing through a pump; it is finally sent to a decantation tank. An app. is specified.

Storing heat chemically. HARRY LE ROY CROOKER. *Fr.* 647,572, Jan. 21, 1928. An unstable soln. of AcONa (contg. 40% water) 500, CaCl_2 6.25 g. and 6% of water is used as a heat-storing medium.

Use of hydrogen for cooling steam turbo-generator sets. MASCHINENFABRIK OBERLION. *Brit.* 297,109, Sept. 15, 1927. H_2 used is obtained by reduction of the steam, e. g., by oxidation of iron; during peak loads H_2 may be drawn from an accumulated reserve supply while the full supply of steam is used.

Removing stains from fabrics, paper, etc. A. WARTEL. *Belg.* 351,152, June 30, 1928. The stain is covered with a mixt. of H_2O , KMnO_4 , H_2SO_4 , and HCl and then with a mixt. of Na_2SO_3 , S and H_2O_2 .

Expansion unit for refrigerating apparatus suitable for use with sulfur dioxide as refrigerating agent. WILLIAM E. LEIBING (to Magnus Fruit Products Co.). U. S. 1,708,390, April 9. Structural features.

Purifying sulfur dioxide in refrigerating systems. A. C. THAYER. Brit. 296,498, June 16, 1927. A chamber filled with Fe or Zn chips is placed in the circulating system to remove any corrosive acids formed in the refrigerant.

Insulation for electric conductors exposed to high temperatures and to the action of oil. J. E. ALLAN and S. B. FREEMAN. Brit. 296,684, March 4, 1927. Flexible elec. conductors suitable for use in boiler rooms or in similar locations are provided with a series of insulation layers of homogeneous reverted or esterified cellulose alternating with layers of pliable material such as fabric tape.

Electric insulation. F. W. HARRISON (to British Thomson-Houston Co., Ltd.). Brit. 297,035, Sept. 12, 1927. Insulation comprising felted cellulose pulp, cotton or other org. fabric or other cellulosic material is freed from trapped air or other gases by immersing the conductors carrying the insulation in an oil bath, which is heated to 120–200°. A bath of PhNO_2 , higher alcs., beeswax, or varnish also may be used.

Electrical insulation. WILLIAM W. WINSHIP. U. S. 1,707,590, April 2. A covering of strengthening material such as hard rubber or fiber is shrunk onto a body of fused silica which may be in the form of a tube.

14—WATER, SEWAGE AND SANITATION

EDWARD BARTOW

Twenty-second annual report of the Metropolitan Water Board for year ending Dec. 31, 1927. ALEXANDER HUSTON. 101 pp; *Pub. Health Eng. Absts.* E-785a, 40.—Considered financially, the use of CI has made unnecessary expenditures of large sums of money for addnl. storage accommodation and increased filtration area. The important effect of storage upon the raw Thames, Lee and New River waters is presented in a series of tables indicating decided improvement bacteriologically. As a result of 40 months of tests at the Barn Elms filters in which stored water was first treated in rapid filters at a rate of 134 gals. per sq. ft. per hr. and then passed through the exptl. filter at 3 or more times the customary London rate (which was less than 2 gals. per sq. ft. per hr.), the following results were obtained under comparable conditions: (1) a final effluent product practically as good, on the av., as that resulting from the ordinary slow sand filtration process; (2) comparative freedom from algal trouble or those caused by an excess of suspended matters, owing to the useful work carried out by the primary filters; (3) a much greater output of water per acre of filtration area, allowing for the space covered by the primary rapid filters per unit of time. Treatment of raw Thames River water stored in the Walton reservoirs by rapid filters at a rate of 119.7 gals. per sq. ft. per hr. followed by secondary filtration at 5.1 gals. per sq. ft. per hr. and chlorination at 0.261 p. p. m., showed a reduction in *B. coli* from pos. in 82.9% of 1 cc. samples to neg. in 96.4% of 100 cc. samples. Favorable rates of filtration and chem. results were also obtained. Certain tests with non-spore-forming aerobic, lactose-neg. microbes show that with waters not giving, so far as is known, rise to disease, there are apparently no microbes occurring on the "rehipelagar" and "rehipesagar" slopes, made from the primary lactose bile salt peptone media, liable to be mistaken for the bacteria belonging to the food-poisoning group. C. R. F.

Design of small water works system. JULIAN MONTGOMERY. *Can. Eng.* 56, 345(1929).—The 5 major considerations in planning a water-works system for a small city are promotion, financing, design, construction and operation. E. HERWITZ

Establishing classifications of public water supplies of West Virginia. First official classification. E. S. TISDALE. *W. Va. Coll. of Eng. Tech. Bull.* No. 1, 8–12 (1927).—For 12 yrs. the Division of Sanitary Engineering of the W. Va. State Health Dept. has been grading public water supplies as (1) good, (2) doubtful, and (3) bad, based on kept yearly bacteriol. records and on periodic inspection of the water supply or treatment plant by trained sanitary engineers. (1) are from properly constructed and adequately protected plants, which produce over a certain period of time water equal to or better than the U. S. and State bacteriol. standard. (2) include those plants

shown to be slightly faulty in operation but which produce a water which meets standard 90% of the time. (3) include those plants of faulty design and without protection and which are unsafe an unreasonable portion of the time. One hundred and fifty-four cities of over 500 population have been classified; 82 with 433,408 population as good, 44 with 78,234 population as doubtful and 28 with 47,001 population as bad. A map showing the location of these places, whether surface or ground is used, and the kind of treatment, is attached.

C. H. BADGER

Clarksburg, W. Va., filtration plant. Performs many extra services for public. PERKINS BOYNTON. W. Va. Coll. of Eng., *Tech. Bull.* No. 1, 27-30, Nov. 1927 (Series 13, No. 3).—Some of the different and occasional unusual uses by the public of such instruments as gages, thermometers, barometers, etc., set up by the Weather Bureau in the plant are mentioned as an aid in creating good will. An educational campaign by means of circulars and free personal supervision and advice regarding sanitary privies, septic tanks, wells, etc., is being conducted to improve the water shed. The plant produces 3,000,000 gals. of water per day. Alum and sometimes lime are used as coagulants. Cl is added to the filtered water.

C. H. BADGER

Grafton, W. Va., new filtration plant. JOHN M. RICE. W. Va. Coll. of Eng., *Tech. Bull.* No. 1, 93-6, Nov., 1927 (Series 13, No. 3). The proposed plant, sufficient to 1945, will consist of 4 equal units supplying 3,000,000 gals. per day. Three units will be built now. Coagulation basins, rapid sand filters and Cl after filtration will be used. Certain improvements, especially in the reduction of high-working pressures, and provisions against possible breaks in the main in the present over-worked system are described.

C. H. BADGER

Wheeling, W. Va., filtration plant. Operating data and costs. G. F. RICKARD. W. Va. Coll. of Eng., *Tech. Bull.* No. 1, 75-89, Nov., 1927 (Series 13, No. 3), cf. *Ch. Eng.* 19, 396, 1908. A machine successfully feeding pulverized quicklime into the water is used. Detailed graphs attached show daily pumpage, hourly filter runs, lime and alum added, turbidity, Fe, Cl, and alk., or acidity in raw and filtered water from June, 1925 to Jan., 1928. The av. lb. free Cl added per million gals. was 2.10 in 1925, 1.84 in 1926 and 2.19 in 1927, min. 0.98, max. 4.58. A graph shows the large reduction in the typhoid fever rate. Av. bacteria found in the raw water at 37° was 2110, in settled water 207, in filtered 16, in finished 10. Operating costs for 1919-27 are given.

C. H. BADGER

Data on rapid sand filtration plants. T. C. HENSHEN. *Can. Eng.* 56, 327 (1929). Space is conserved and economy effected by building rectangular sand filters and by using the walls to support the building covering them. Other factors to be considered in building a filter of given capacity are size and no. of units necessary for efficient operation, keeping in mind future requirements, depth of filter, the under-drain system, selection of filter medium, wash troughs, controls for uniform flow and gage to prevent loss of head.

E. HURWITZ

Water-sampling apparatus (Olszewski-Keyl). W. OLSZEWSKI. *Chem. Ztg.* 53, 149 (1929).—A modified Spitta-Imhoff sampler for water, to open automatically at specified depths, is described briefly.

W. C. ERAUGH

Water-sampling devices for the water works operator. J. D. E. BRIHAM. *Man. News and Water Works* 75, 3-4 (1928); *Pub. Health Eng. Abs.* E 739, 26. Four types of water samplers are described.

C. R. F.

Rapid titrimetric determination of sulfate in drinking and service waters with the aid of visual conductivity titration. H. FEHN, G. JANDER AND O. PFUNDT. *Z. anorg. Chem.* 42, 158-9 (1929).—Boil 50 cc. of water to cause deposition of CaCO_3 . Cool to freezing mixt. to room temp. and filter into the cond. glass. Add an equal vol. of alk. and titrate quickly with standard $\text{Ba}(\text{OAc})_2$ using a mirror galvanometer instead of a telephone for the cond. detn. The whole detn. can be carried out in 10 mins.

W. T. B.

What price safe drinking water. PERKINS BOYNTON. W. Va. Coll. of Eng., *Tech. Bull.* No. 1, 21-7, Nov., 1927 (Series 13, No. 3).—A semi-technical discussion of the natural sources of water supplies, natural and artificial purification, mechanism of filter action and the control tests used in a modern filter plant.

C. H. BADGER

Drinking water from sea water. H. T. ELLIS. *Dock and Harbor Auth. (London)* 8, 71; *J. Am. Water Works Assoc.* 20, 592 (1928).—Purification by freezing and by distn. is discussed.

D. K. FRIEDMAN

The catalytic power of medicinal mineral waters. OMBULIO FERNANDEZ. *Rev. Soc. esp. fis. quim.* 27, 45-8 (1929).—Many theories have been proposed. It is not a question of decompn. of H_2O_2 by microorganisms contained in or introduced into the H_2O during bottling or testing in the lab. The microbes in H_2O contain a class

H_2O_2 to H_2O and mol. O. Detns. of catalytic activity are valueless in test-mineral waters unless made only to det. bacterial purity. E. M. SYMMES
—ses in natural mineral waters. G. GUIDI. *Arch. intern. pharmacodynamie* 3(1928); *Physiol. Abstracts* 13, 222.—The reagent employed for showing the of oxidases was not affected by atm. O. It was a specially prepd. leuco base from malachite; in AcOH it turns to turquoise in the presence of O, being very sensitive. It is a yellowish amorphous powder sol. in dil. acid. The change for is certainly due to an oxidative reaction. A millinormal soln. of KMnO_4 dild. required was used for contrast with the sample of water, and gave a measure of the value of the color change. The intensity of the reaction varies in different varieties of mineral water and in samples of the same water at different seasons and periods after collecting. H. I. D.

Approved water-purification apparatus at "The Technical City" exposition in Dresden. OSKAR KAUSCH. *Chem. App.* 16, 49-51(1929).—Softening, chlorinating and clarifying app. are shown, with 6 cuts. J. H. MOORE

Water purification. S. R. DE BRITO. *Rev. brasil. engenharia* (Rio de Janeiro) 15, 165-7; *J. Am. Water Works Assoc.* 20, 732(1928).—A discussion of drifting sand filters and of the use of lime and Al sulfate. D. K. FRENCH

• The problem of purifying water by coagulation. I. I. KRASIKOV AND A. LITYAGO. *Zapiski Belorusskoi Gosudarstvennoi Akad. Nauchn. Khim. i Tekhn. (Memoirs Belorussian State Acad. Agr.)* 4, 261-70(1927).— $\text{KAl(SO}_4)_2 \cdot 12\text{H}_2\text{O}$ and $\text{Fe}_2(\text{SO}_4)_3 \cdot (\text{NH}_4)_2\text{SO}_4 \cdot 12\text{H}_2\text{O}$ were used as coagulants and the amounts necessary to coagulate the particular water without increasing the Al content was studied. The K alum proved to be the better coagulant and by the addition of 0.1 g. per l. did not increase the Al_2O_3 content. J. S. JOFFE

Water purity increased by progress of chlorination. W. J. ORCHARD. *Water Works Eng.* 81, 404; *J. Am. Water Works Assoc.* 20, 712-3(1928).—The increasing use of Cl in both water and sewage treatment is considered and its limitations are outlined. D. K. FRENCH

Effect of chlorine on alum reaction. WILLIAM B. MEYER. *Proc. 2d Ann. Mich. Conf. on Water Purif.* 1928, 35-40; *Health Eng. Abs.* E-739, 26.—It was observed that where Cl was added to Huron River water previous to coagulation, the reaction of the floc was sharper and also faster, giving a better color removal. The tests indicate that where Cl is added to raw water in excess of 1 p.p.m., a reduction of from $\frac{1}{2}$ to 1 grain of alum per gal. may be made, where formerly the alum added was 3 grains. This reduction, however, also depends on the amt. of Cl that may be used without producing a noticeable taste. C. R. F.

Comments on methods for determination of residual chlorine. LINN H. ENSLOW. *Sewage Works J.* 1, 30(1928); cf. *C. A.* 23, 1972.—Of the 4 well-known methods for the detn. of residual Cl, e. g., (1) starch iodide titration, (2) starch iodide colorimetric, (3) benzidine-HCl, (4) o-tolidine, the last named seems to be most reliable as an index of effective chlorination of sewage. Iron and nitrates do not interfere with color development. Manganous compds. and nitrites do. Other factors that must be considered when using this method are pH value, temp., and time of reaction. E. HURWITZ

Improvements in equipment and technic of operation of chlorine disinfection apparatus. R. C. CLEMENT. *W. Va. Coll. of Eng., Tech. Bull.* No. 1, 90-2, Nov., 1927 (Series 13, No. 3).—There are about 130 places in W. Va. now using Cl disinfection machines, about 80 of which are the pulsating meter type. Certain reminders in the operation of this machine are given. The place and use of o-tolidine as a control for dosage are described. The advantages of new, manually controlled- and semi-automatic-soln. feed machines are given. C. H. BADGER

Sterilization of water by chlorine. F. DIENERY AND P. FERRILLARD. *Compt. rend.* 188, 826-9(1929); cf. *C. A.* 22, 610, 3008.—The hypothesis is adhered to that the sterilizing action of Cl is derived from its ability to unite with the org. protoplasm of bacteria and to destroy them. Approx. 1000 cells of *B. coli* and *B. typhosus* were introduced into 2 flasks of River Seine water filtered through Chamberland bougies. Sterilization was effected by 0.2 mg. Cl after 2 to 24 hrs. according to the org. content of the water. The same results were obtained when 0.4 mg. $\text{Na}_2\text{S}_2\text{O}_4$ was added to destroy the free Cl 5 mins. after its introduction. To River Seine water after sterilization by passing through a bougie, 0.2 mg. of Cl was added followed in 5 mins. by 0.4 mg. of $\text{Na}_2\text{S}_2\text{O}_4$, which destroyed all of the free Cl present; finally 1000 cells of living *B. coli* or *B. typhosus* were added. After 24 hrs. all the bacteria were still viable, that is, there was present in the water no antiseptic substance except the free Cl itself. Conclusion:

As long as a water carries free Cl as indicated by the *o*-tolidine test, all cells or *B. typhosus* are destroyed. Thorough mixing of the Cl and water is advised. C. R.

Note in regard to the manganese determination in water. J. DE Weekblad 26, 103-4(1929).—In samples of H_2O which cannot be analyzed short time a certain amt. of Mn adheres to the sides of the bottles, and if not may cause a considerable discrepancy in the analysis. It will most likely be in H_2O from which a sediment of $CaCO_3$ has formed. J. C. J.

Treatment of water supply for iron removal. E. V. PEDERSEN. Am 126-7; J. Am. Water Works Assoc. 20, 733(1928).—Aeration, coagulation and filtration are discussed. D. K. FRENCH

Note on base-exchange water softeners. C. O. CLARK. Soc. Dyers Colourists 45, 36-9(1929).—Base-exchange systems, both natural and synthetic, of softening water are compared with chem. systems, and information is furnished regarding points of superiority of the latter. Facts are given regarding the proper maintenance of base-exchange water-softening plants and the advantages of water of zero hardness over hard in the textile, tanning and paper industries. H. H. MOSHER

Natrolite filter for softening water. STEN TYNEN. Gefle, Sweden. Svensk Kem. Tid. 40, 250-6(1928).—A Swedish water softener, "Natrolite," is analyzed and tested. It is closely related to the American "Zeolite" and contains: SiO_2 62.9, Fe_2O_3 8.5, Al_2O_3 17.0, TiO_2 1.0, CaO 1.4, MgO 1.3, K_2O 1.9, Na_2O 2.7, H_2O 3.3 and difference from 100%, 0.11. Tap water was allowed to flow through the filter at 4 l. per day and l. samples analyzed from time to time. The original material was not very efficient. The filtering properties renewed by salting and washing caused it to remove completely the alk. earths in the first 15 l. One cu. m. softens 112.4 (metric) tons of local water [8.6 CaO and 0.9 g. MgO per 100 l.]. A. R. ROSE

Water softening on a large scale by the zeolite process. H. C. KNEELAND. W. Va. Coll. of Eng., Tech. Bull. No. 1, 66-74, Nov., 1927 (Series 13, No. 3).—A description of the 4-million gal. zeolite water-softening plant is given. The 4 units consist of covered horizontal steel tanks 9×22 ft., operated under 5 lbs. pressure; they are similar in construction to rapid sand filters. They contain 39 in. of green sand (100 cu. ft.) uniformity coeff. 1.46, 60% finer than 0.51 mm. and 10% finer than 0.35 mm. over 18 in. of 2 grades of gravel. The loss of head in green sand is about twice that of filter sand of the same size. The water is reduced 12-15 to 4-5 grains hardness (water of 0 hardness is objectionable because of its persistent lathering qualities) by operating the units on a prearranged time schedule. Water of 0 hardness is delivered at the rate of 4.5 gals. per sq. ft. per min. for 3.5 hrs., which exhausts the filter; hard water then continues to pass for 1 hr. when the unit is taken out of service for 0.5 hr. for regeneration. An inadequate dose of brine is used in order to cause hard water to appear at just the proper time. The softener has also eliminated trouble from clogged filters by removing 2.5 p. p. m. Mn and the crenothrix which fed upon it. Total cost of plant not exceed \$0.03 per 1000 gals. C. H. BARNES

Tastes and odors in water supplies with special reference to waste liquors from by-product coke plants. W. W. HOBBS. W. Va. Coll. of Eng., Tech. Bull. No. 1, 40-54(1927)(Series 13, No. 3).—A review and discussion of the classes of materials causing bad odors or tastes in water are given. Although the pipe and fittings of an old line were burned well before reconstructing into a water line delivering to Morgantown, W. Va., an oily taste persisted in the water for weeks. A tabulation of experiments on by-product waste liquors by 8 collaborators is given. It was detected by 7 in 1 to 1000 ppm. Waste liquors from a by-product plant going into the Monongahela River 20 miles above Morgantown caused disagreeable tastes at the intake. After the study of different methods the company recovers 96% of the phenolic wastes by the use of two sets of counter scrubbing towers. Cf. C. A. 22, 2358. C. H. BARNES

Eliminating tastes and odors by algae in water. C. COHN. Am. City 38, 12-13, 1928. J. Am. Water Works Assoc. 20, 446(1928).—C. describes the use of $CuSO_4$ and $Al_2(SO_4)_3$. D. K. FRENCH

Control of algal growths in the water supply of Los Angeles. C. WILSON. West Constr. News 3, 355-6; J. Am. Water Works Assoc. 20, 732(1928).—The use and methods of application of $CuSO_4$ are described. D. K. FRENCH

The protection of impounded reservoirs. HELMAN ROSENTHAL. Mun. Eng. and Water Works 75, 85-8(1928).—As a result of information obtained through replies to a questionnaire and from R.'s own studies on the Dallas water supplies, it is concluded that from use for recreational purposes can be made by reservoir drainage areas if proper sanitary regulations are enforced. C. R. F.

venting corrosion by water treatment, deaeration, deactivation. H. T. HALL. *Eng.* (Chicago) 124, 29-32; *J. Am. Water Works Assoc.* 20, 730-1(1928).—

the methods mentioned in title represent those in general use. D. K. FRENCH

latest developments in feed-water treatment. D. BROWNLIE. *Eng. and Boiler Rev.* (London) 41, 533-4; *J. Am. Water Works Assoc.* 20, 591(1928).—A review of developments in America with especial reference to embrittlement and to the uses of gases and phosphates. D. K. FRENCH

Modern treatment of supplementary feed water for steam power plants. BALCKE. *Wärme* (Berlin) 51, 411-6; *J. Am. Water Works Assoc.* 20, 729(1928); cf. C. A. 22, 2018.—The paper is devoted largely to a discussion of the advantages of evapn., aeration, and thermochem. treatment of water. D. K. FRENCH

Treatment of feed water for evaporators. T. A. SOLBERG. *Mar. Eng. and Shipg.* Age 33, 283; *J. Am. Water Works Assoc.* 20, 443(1928).—S. recommends the use of Na silicate. D. K. FRENCH

Deoxygenating feed water. CHR. HUELSMEYER. *Eng. Progress* (Berlin) 11, 118; *J. Am. Water Works Assoc.* 20, 443(1928).—H. describes a device that uses manganese-steel wool. D. K. FRENCH

Filtering and softening boiler feed water. H. M. MARSH. *Power House* 22, 33-4; *J. Am. Water Works Assoc.* 20, 591(1928).—M. describes the use of sand filters with and without zeolite softeners. D. K. FRENCH

Treating boiler water. L. M. WILLIAMS. *Refiner Natural Gasoline Mfr.* 8, 98, 100, 102(1929). A treating plant for the treatment of water having high sulfate and chloride content and chem. control methods for such a plant are described. M. B. HART

Chemical and physical changes in a cast-iron well casing. G. THIEM. *Gas u. Wasserfach* 71, 1239-41(1928).—A cast-iron well casing that had been in use for about 30 yrs. under a water with an av. CO_2 content of 56.3 mg./l., showed a sp. gr. of 2.97 as compared to a normal sp. gr. of 7.25. The Fe content had decreased from about 93% to 52% and the percentages of C, Mn, Si, P and S had increased. The casing retained its shape and would have been usable if left in place, and not subjected to mechanical stress. R. W. RYAN

The significance of the colon bacilli in water. Its relationship to the typhoid organism. Tests for *B. coli*. R. S. SPRAY. *W. Va. Coll. of Eng., Tech. Bull.* 1, 13-20, Nov., 1927.—S. discusses the difficulties of finding the typhoid bacillus in water as there are probably not more than 20 proven instances of its isolation even in water known to be polluted or which caused epidemics. Fecal streptococci (a), proteolytic and fermentative anaerobes (b), and the colon bacillus group (c) as indices of pollution, and the unreliability of (a) and (b) as such are discussed. The differentiation between *B. aerogenes* and *B. coli* is shown. S. would not condemn a water which shows a low total count and gas in more than 1 tube if the gas is *B. aerogenes*. C. H. BADGER

Notes on Doncaster (England) sewage disposal scheme. W. H. PRICE. *Munic. Eng. Sanit. Record* 82, 105(1928).—Land drainage is to be replaced by a sewerage system consisting of a new intercepting sewer costing £50,000, detritus, storm water, settling and humus tanks, sludge lagoons, and percolating filter beds. Much of the equipment will be electrically driven. C. H. BADGER

Losses caused by heating liquefied sewage solids. H. HECKELEKIAN. N. J. Agr. Expt. Sta., New Brunswick. *Ind. Eng. Chem.* 21, 324-5(1929).—Sewage solids in soln., when dried at 100-5° lost from 33 to nearly 100% of their C, the % increasing with the ripeness of the sludge. There is also a considerable loss in N. The loss in wt. due to drying ordinary sewage may reach 25% of the total solids. Low gas yields accompanied by decrease in volatile matter in dried sewage is explained on this basis. C. R. F.

Control of scum in sewage tanks. A. M. BUSWELL. State Water Survey Div., Urbana, Ill. *Ind. Eng. Chem.* 21, 322-3(1929).—Liquor from beneath the scum was pumped and allowed to flow on to the scum in a gentle stream. Ten days' circulation under these conditions completely disintegrated a 26' layer of stiff scum and the gases evolved during digesting were allowed to escape smoothly into the gas collector. Circulation for from 5 to 10 mins. a day prevented any further scum formation. Circulation for 3 to 5 mins. at a time was sufficient to break the foam, and routine circulation for 5 to 10 mins. per day was usually sufficient to prevent foam formation. Power costs will not be high, and the method is effective. J. A. KENNEDY

Activated sludge plant at Grand Canyon, National Park, Arizona. JANE RIDER. *Southwest Water Works J.* 10, 12-4; *J. Am. Water Works Assoc.* 21, 157(1929).—This

article describes in more or less detail the plant equipment, operating details obtained.

Modern public cleansing and salvage. A. L. THOMSON. *Munic. En. Record* 82, 125-6, 150-1, 176-7(1928).—A discussion. T. holds that the ha sorting of refuse does not generally cause disease.

D. K.

C. H. B.

The use of p_H control in a sanitary laboratory. LEWIS V. CARPENTER. V Coll. of Eng., *Tech. Bull.* 1, 55-65(1927).— p_H control has made it possible to when sufficient chemicals have been added for coagulation; otherwise, both insol. and sol. Al is usually found in the effluent. Expts. on these pptns. were made in qt. jars on 6 local waters. When sufficient alk. was present, the p_H value corresponding to the amt. of alum which gave the quickest floc was the optimum. When alkali was necessary, a known amt. of alum was added (2 grains per gal.), and the amts. of Na_2CO_3 and lime were varied until the best floc was obtained. After obtaining such p_H value the min. amts. of chemicals needed for coagulation were found by further tests. A procedure for the control of plants is given, based on keeping the p_H value at an optimum point. Such point will sometimes have to be retd. because of variations in the supply. It may be more economical to add less chemicals than are needed to give the optimum p_H value if sufficient time is allowed for settling. Indicators were used in the tests.

C. H. BADGER •

Chlorination in the field of sanitation. LINN H. ENSLOW. Chlorine Inst., Inc., N. Y. *Eng. J. Can* 12, 135-40(1928), cf. *C. A.* 22, 1818, 23, 1455.—New uses of chlorine in the treatment of sewage, in water conditioning, in decolorizing of stack gases and in the treatment of "white water" from paper mills, are described in this paper. Prechlorination of sewage inhibits the formation of H_2S and the consequent production of H_2SO_4 , which disintegrates the sewers. Objectionable odors from manholes, weirs and filter sprays are diminished, flocculation of non-settleable matter in the flow chambers is obtained and the growth of algae and sludge-producing organisms reduced by prechlorination of the sewage. Chlorination reduces the oxygen demand of sewage. Slime-like growth in the vats, stock chests, etc., of paper mills is reduced by chlorination of the "White water"; this permits the recirculation of this water for use in the mill. Chlorinated ferrous sulfate makes a very satisfactory coagulant in water purification. Chlorine applied to the exit gases from meat packing establishments, garbage-disposal plants and other objectionable odor-producing stacks reduces the nuisance by destroying the odor-producing compounds.

J. W. SHIPLEY

The treatment of organic waste. W. WEAVER. *Munic. Eng. Sanit. Record* 82, 97(1928); cf. *C. A.* 23, 1975.—At the Birmingham, England, plant, vegetable matter is thoroughly pulverized and dried for fertilizer. Foreign materials are extracted. The treatment of fertilizers and feeding meals is kept separate.

C. H. BADGER

Eliminating turbidity and trade wastes. C. E. RICKARD. *Water Works Eng.* 81, 671-2, 686, 689-90, 693; *J. Am. Water Works Assoc.* 20, 592(1928).—Operating experiences and results obtained at the new Wheeling, West Virginia, plant are discussed.

D. K. FRENCH

The comparative values of air treatment as applied to ventilation. W. H. DUPRE. *Domestic Eng.* 48, 3-7(1928); *Bull. Hyg.* 3, 668-9.—A device is described by means of which it is possible successfully to collect flue dust at chimney tops as an alternative to the method of lengthening chimneys and slowing up the air column moving through them in order to settle the flue dust by gravity. It is also suggested that spacious roof chambers be used as dust settling chambers; in this manner frequent cleaning of dust filters is avoided. The removal of dust from air is best achieved by washing in a fine water spray, and then removing the excess moisture by impinging the air on oil-coated surfaces.

C. R. F.

Determination of dust and smoke in the inhaled and exhaled breath of man (DRINDER, et al.) 13. The determination of alkali in seepage water [in oil wells] (MAL'YAROV) 7. Differences observed in the conditions of the sea water at the margin 2 opposing tidal currents (THOMPSON, MILLER) 11A. The character of ground water in Balakhanui (KREMS) 22. New ways for sterilization [of water] (DECKWITZ) 11C. Turbine corrosion and degasification (PARIS) 9. Mixing and precipitation apparatus suitable for precipitating saccharates from Steffens waste waters (U. S. 1,708,332-28.

Water filter. GEORGE J. MEYER. U. S. 1,708,140, April 9. Structural features.
Valve for water-softening apparatus. BENJAMIN H. TEN BUNST. U. S. 1,701,602, April 2. Structural features.

707,302, April 2 An app. is described comprising a series of inclined chambers contacted by intermediate vertical chambers, with rotatable screw conveyors in the inclined chambers, in which the entire charge of base-exchange material is uniformly agitated and circulated during the stages of the process. Raw water is passed through mineral in one phase of the process and the exhausted mineral is reconditioned in another phase.

Apparatus for separating oil from boiler-feed water. THOMAS A. SHORT. U. S. Pat. 2,303,883, April 9. An alarm device is provided for indicating when oil accumulates in the feed-water supply.

Sewage-sludge digestion. M. PROCESS Brit 297,250, Dec. 8, 1927. To maintain the temp. in a sludge digestion chamber at about 25°, the fresh sludge, before introduction into the chamber, is heated to above this temp. An app. is described.

Septic tank. CHARLES L. CARLISTER and WILLARD E. JAQUITH. U. S. 1,708,118, April 9. Structural features.

15—SOILS, FERTILIZERS AND AGRICULTURAL POISONS

J. J. SKINNER

The factor of climate in the genesis and classification of soils. H. M. NAGANT. Institut Agr. d'Oka, La Trappe, P. U. *Sci. Agr.* 9, 321-34(1929).—The literature and some data are discussed, showing the great importance of the climate factor in soil genesis and classification. C. R. F.

The dynamics of the physicochemical processes in the soil. S. I. BUNTYAKOV. *Zhurnal Opušnoi Agron. Yugo-Vostoka (J. Expt. Landw. Sudost. Eur.-Russlands)* 3, No. 2, 60-74 (1927); *Eng. Abstr.* 171, *Expt. Sta. Record* 58, 612 3.—Summarizing the results of expts., the author states the following conclusions: (1) The influence of tillage is definitely expressed in the intensity of the process of nitrification; tillage has little or no influence on the mobilization of other nutrients. (2) The porosity of the plowed soil drops toward autumn, the greatest porosity was noted in the chernozem soils, followed by the columnar solonch and finally the dark-chestnut and sandy soils. (3) Favorable conditions for the accumulation of nitrates are from 60 to 66 per cent aeration, 23 to 26 per cent of moisture, and 17 to 22° temp. (4) Following a soil increases the amt. of nitrates 3 times over that of a soil left undisturbed; spring crops increase the nitrates only twice. (5) With a May fallow the max. accumulation of nitrates takes place in July, with spring crops in June. (6) The changes in the amts. of nitrates in various types of soils under conditions of uniform tillage are about alike and may be expressed by identical curves. (7) Under conditions of uniform tillage in various types of soils the max. accumulation of nitrates is quantitatively alike and is to be noted during the month of June. (8) Spring wheat exerts a strong influence on the amts. of nitrates and lime, in respect to other nutrients its influence is negligible. (9) The greatest loss of nitrates under spring wheat takes place on chernozem and dark-chestnut soils; little less on the columnar and sandy soils. This phenomenon is especially marked on all soils at the time of forming the straw. H. L. D.

A comparison of the Robinson, International and Buoyoucos methods of mechanical analysis on non-organic soils and the analysis of such soil with and without preliminary treatment with hydrogen peroxide. J. H. DENNETT *Malayan Agr. J.* 16, 374-7 (1928).—The international method is interchangeable with the Robinson method from which it may be readily obtained by interpolation of the summation curves. As a matter of convenience it is as accurate to det. the clay fraction at the end of 24 hrs. at a depth of 30 cm. by the International method as at the end of 8 hrs. at a depth of 10 cm. It is unnecessary to use H_2O_2 for preliminary treatment of non-org. soils. The methods of Buoyoucos are of great utility for routine purposes for detg. the general limits of the soil concerned. It is more accurate to det. the total sand by direct sedimentation in this latter method rather than by difference. E. F. SNYDER

An improved method of fusion for soils. J. H. DENNETT. *Malayan Agr. J.* 16, 372-8 (1928).—Caustic potash is used in place of Na_2CO_3 and 2 objections to its use are overcome, namely, by previous fusion of the caustic potash and by the use of Ni crucibles instead of Pt. The Ni crucible is only slowly attacked by caustic potash and most

Ni removed in this way does not seem to go into soln. in the acid but filter paper. Any Ni which goes into soln. does not affect the detn. of alumina. The great advantages of this method of fusion lie in the rapidity & it is carried out (a few min. to a quarter of an hr.) and the completeness with sesquioxides and silica are broken down. E. F. SNYDER

The use of highly viscous fluids in the determination of volume-weight. S. H. BACKSTETTER. Calif. Agr. Expt. Sta. *Soil Sci.* 25, 481-3(1928).—The method for vol.-wt. detns. was as follows: The soil mulch was removed from an 11 3 sq. ft. carefully leveled. An auger hole was then put down to the depth soil removed being conserved and its dry wt. obtained by drying out at a 11 F. The auger hole was then rapidly filled with the fluid, heavy road heavy cane sirup, the vol. added being detd. by weighing the container and before and after filling the hole. From the dry wt. of soil and the vol. of the fluid, the vol.-wt. was detd. The trials thus far conducted with this method indicate that it furnishes a rapid and accurate means of verifying the results of vol.-wt. detns. as obtained by the soil-tube method. Comparative results are given in a table. E. F. SNYDER

The colorimetric estimation of phosphorus in acid soil extracts. W. N. C. BELGRAVE. *Malayan Agr. J.* 16, 361-71(1928).—The direct application of the Denigès colorimetric method to acid soil exts. is frequently impossible because of ferric iron and the need of H-ion control. A method of reduction with Zn. and H-ion control with acetates, thymol blue being used as an indicator, is described. Comparative results on different soils between the colorimetric and the volumetric methods are given. Results of analyses, by different methods and different workers, of test solns. are given. It is claimed that the colorimetric method, as modified, is sufficiently accurate, easy to manipulate and particularly suited to tropical labs. E. F. SNYDER

Soil surveys once more. F. S. EARLE. *Facts About Sugar* 24, 64(1929), cf. C. A. 23, 460.—E. agrees with Koningsberger that the physical soil type and the Arrhenius methods of soil analysis are complementary. Some remarks on Prof. Earle's article. O. W. WILLCOX. *Ibid.* 65. M. J. PROFFITT

Some comments on soil surveys in Java and Cuba. A. G. MCCALL. *Facts About Sugar* 24, 158-60(1929); cf. Willcox, C. A. 22, 4701; Earle, C. A. 23, 228.—Modern soil science undertakes to group soils on the basis of all their definitely determinable characteristics, chemical and physical as well. Bennett and Allison (C. A. 22, 2801) made their classification of Cuban soils primarily as a guide for experimentation. The *pu* of every detd. type of soil in the island was looked into as a matter of course, but not in such detail as was necessary in Arrhenius' studies of Java soils. As reported by W., A. found between the best soils and the most acid ones in Java a max. diff. in yield of sugar of only 6.5%, while B. and A. found yield differences equiva. to over 200% in sugar production due solely to differences in the physical conditions of the types of soil compared. The physico-mechanical versus the plant physiological basis of soil surveys. O. W. WILLCOX. *Ibid.* 160.—W. replies to M. M. J. PROFFITT

Some remarks upon the investigation of Java soils. C. H. VAN HANDEL. *Facts About Sugar* 24, 226-7(1929).—Historical M. J. PROFFITT

The profile of a common sandy soil type in Norfolk County, Ontario. F. F. MURPHY. *Ontario Agr. Coll. Guelph. Ser. Agr.* 9, 301-12(1929).—The acidity was highest in the leached horizon of the virgin soils and in the surface horizon of the cultivated soils. The virgin soils contained more org. matter and were more acid than the cultivated soils. The max. colloidal content is in the lower surface horizon and is held to be an important factor in controlling the moisture supply. Org. matter was highest in the surface layers. C. R. FELLERS

Technic of pot experiments (with plants). E. MAIWALD. *Agrikulturchem. und bakteriol. Inst. der Univ., Breslau. Landw. Vers.-Sta.* 107, 342-63(1928).—The whole technic is reviewed and various minor errors are discussed. E. F. SNYDER

The decomposition of urea in sand cultures and in soil. KLEMMER. *Landw. Vers.-Sta.* 107, 296-301(1928).—The speed of decompn. varies with the texture of the soil; in general, the lighter the soil the quicker the decompn. Heating to 300° or treatment with 2% HCl destroys these differences, but they persist after treatment with CHCl₃. E. F. SNYDER

Field and vegetation experiments on mineral soils showing exchange acidity. ROEMER. *Landw. Vers.-Sta.* 107, 307-14(1928).—By using kainite rather than other K salts substantially higher yields of rye and oats were obtained in field expts. Pot expts. in which the several constituents of kainite were employed showed that the benefit could be ascribed to Mg salts. This explanation was further substantiated by a comparison of Mg phosphate with other phosphates. E. F. SNYDER

Decomposition of peat measured by carbon dioxide evolved. ROBT. H. BEDFORD. Univ. of Alta, Edmonton. *Sci. Agr.* 9, 522-32(1929).—The object of the expt. was to determine whether the measurement of CO_2 evolved is indicative of the fertility of sphagnum peat. Chem. and bacteriol. examns. as well as vegetative pot expts. were carried out on an undecomposed peat contg. 43.4% C and 1.31% N. The filtrate resulting from 2% acid hydrolysis of straw being used as an energy medium with or without the fn. of inorg. salts, the CO_2 evolved and the N fixed were measured daily for 2 weeks. The rhythmic rise and fall of CO_2 evolved was analogous to the fluctuations in bacterial N and K were limiting factors for plant growth in the peat soils. N fixation increased steadily for 2 weeks and CO_2 evolution decreased greatly. Conclusion: CO_2 evolution cannot be used alone as an index of fertility when applied to peat soils. Fungal population is characteristic of sphagnum peat. C. R. FELLERS

Conditions of formation and constitution of the argillo-humic complex of the soil DEMOLON AND G. BARRIER. *Compt. rend.* 188, 654-6(1929).—Colloidal clay is a factor in fixation of the humic colloids in the soil. The investigations of D. and B. furnish exptl. basis for the notion of the argillo-humic complex. The cations absorbed by the clay, and in particular Ca, condition the formation of this complex, which can be reproduced by starting from its constituents and which permits of the equil. reactions. E. F. SNYDER

A study of nitrate production in virgin soils of Alberta. ROBT. H. BEDFORD. Univ. of Alta, Edmonton. *Sci. Agr.* 9, 301-9(1929).—Four soils were examd. A definite relationship was found between % org. matter, bacterial nos. and nitrates. An inverse relationship exists between nos. of bacteria per g. of soil and total org. matter in 100 g. of soil. N is a limiting element in the peat under investigation when measured against the N content of the org. matter of the mineral soils. The nos. of microorganisms of peat and mineral soils are shown to be wholly divergent, when calcd. upon their org. matter content. The soils of Alberta are plentifully supplied with nitrates. C. R. FELLERS

Boron in the soils and irrigation waters of Southern California and its relation to citrus and walnut culture. W. P. KELLEY AND S. M. BROWN. Trop. Agr. and Citrus Expt. Sta., Riverside. *Horticult.* 3, 415-58(1928). B was detd. by distn. with MeOH, followed by double titration of the distillate with standard alkali; *p*-nitrophenol and phenolphthalein were used as indicators and mannitol was used as a catalyzer. One kg. of soil leached with 200 cc. distd. H_2O or 4 l. of irrigation water were used for samples. B free reagents and app. were used. Contents of B that are toxic to citrus and walnut trees occur in certain irrigation waters of southern California. In a few relatively small areas the soil contains an enormous quantity of sol. B, which has probably accumulated as a result of purely natural causes. Citrus trees show the toxic effect of B by a yellowing of the older leaves around the margins and between the veins and a dying back of the tips and margins. The new growth may not show the injury until it is several months old. Many of the affected leaves fall off in the winter and early spring months. When walnut trees are injured by B, the leaves turn brown around the margins and between the veins during Aug. and Sept. Earlier in the year the leaves may not show any evidence of B injury. B-affected walnut leaves tend to fall prematurely. Citrus and walnut trees absorb B readily and this element tends to accumulate in the leaves. The detn. of the B content of the leaves of citrus and walnut trees gives valuable indication as to whether this element is the cause of abnormal leaf conditions. When introduced into the soil as a constituent of the irrigation water, B gradually accumulates in the upper layers of the soil as a result of evapn. Heavy rains probably carry down some of the B from time to time and thus retard the accumulation of sol. B in the region of tree roots. Fourteen references are discussed. C. R. FELLERS

The fixation of atmospheric nitrogen by Azotobacter. OTTO MEYERHOF AND AN. BUNG. Kaiser Wilhelm Inst. für Biologie, Berlin-Dahlem. *Z. physik. Chem.*, Abt. A, *Haber-Bd.* 139, 117-42(1928).—The respiration and N fixation of aerobic *Azotobacter chroococcum* in liquid cultures and short time expts. were investigated. The magnitude of respiration in air is, apart from the activity of different salts of the soln., primarily detd. by the presence of sugar and is in its presence 10 to 15 times as great as in a sugar-free soln. Narcotics and HCN act similarly as with other cells. The magnitude of respiration per unit of dry wt. subsides strongly with the increasing age of the liquid culture, from an initial value (at 20°C). Also, the speed of growth subsides after 24 hrs., which must be traced back to the aggregation of the bacteria. Under av. behavior the increase of the bacteria no., the dry wt. and the N no. run exactly parallel. The max. respiration lies at 15 to 20% of the O_2 content of the atm. and

falls off strongly toward both sides. In pure O_2 the respiration is only $1/3-1/2$ of that in air. In comparison for short periods it is independent of the presence of N_2 , and O_2-H_2 mixts. it is equal to that corresponding to concd. O_2-N_2 mixts. The rise of the respiration as an expression of the growth is, in the absence of added NH_4 salts, independent of the N_2 content of the atm. In O_2-H_2 it is zero; in 1 and 2% N_2 it is not detectable becoming first perceptible at 5% N_2 ; in 20% N_2 it approaches a value as great as that in air. The O_2 concn. has a considerable influence on the magnitude of the fixation and upon the ratio: $\frac{\text{mol. } N_2 \text{ fixed}}{\text{mol. } O_2 \text{ consumed}}$. While the abs. max. of fixation growth lies at 4 to 5% O_2 , the fixation rate increases continuously with decreasing pressure. While in 60% O_2 , however, it is zero, in air 0.003 to 0.008, it is at about 5% O_2 0.02, at 1 to 2% O_2 about 0.03, at 0.12% O_2 about 0.10. The energy output of the oxidation increases therefore with decreasing O_2 pressure, calcd. from air from about 0.5% to about 12%. Also the assimilation of added NH_4 in N_2 -free atm. increases with decreasing O_2 pressure; however, the ratio $\frac{N \text{ assimilated}}{O_2 \text{ consumed}}$ is hereby apparently little altered.

Effect of date of seeding of winter wheat upon some physiological changes of the plant during the winter season. GEORGE JANSSEN. Univ. of Arkansas. *J. Am. Soc. Agron.* 21, 168-200(1929).—Changes in the compn. of the crown of the wheat seedling were studied during 2 consecutive winter seasons. In general there seemed to be a pos. correlation between the total sol. carbohydrate compds. and better dates of seeding or winterhardiness for the yr. 1923. The Sept. 21 seeding, the best date of seeding, showed in 1923, particularly, the greatest % of total sugars as well as total carbohydrate compds. However, for the 2 yrs' results, winterhardiness could not be attributed to the hexose carbohydrate compds. alone. The total N compds. remained about the same throughout the winter months, being somewhat higher in the younger plants than in the older plants. The H_2O -sol. N and sol. N, which is coagulable by heat, increased during the fall months as the temp. decreased. The sol. N, which is coagulable, increased with the lowering of the temp. to the f. p. after which it greatly decreased. The % of H_2O -sol. N which is coagulable was greatest for the favorable dates of seeding, before the plants were frozen, but after freezing occurred, the coagulable N was much less for plants from the favorable than from the unfavorable seedings. The plants from the most favorable dates of seeding have a greater capacity of changing the protein N from a precipitable to a nonprecipitable form.

E. F. SNYDER

The role of potassium in the culture of the sugar beet. J. PH. WAGNER. *C. r. rend. acad. agr. France* 15, 190-3(1929).—The increasing yields, both in roots and in sugar, correspond regularly to the increasing amts. of K salts.

E. F. SNYDER

Soil reaction studies on the Connecticut tobacco crop. P. J. ANDERSON. Conn. Tobacco Substation. *J. Am. Soc. Agron.* 21, 156-8(1929).—Considering both yield and quality the optimum reaction for tobacco soils is between 5.0 and 5.6. An explanation of the injurious effect of extreme acidity is given along with a discussion of how the farmer may keep his soil at optimum reaction.

E. F. SNYDER

Tobacco as an indicator plant in studying nutritional deficiencies of soils under greenhouse conditions. M. F. MORGAN. Conn. Agr. Expt. Sta. *J. Am. Soc. Agron.* 21, 120-6(1929).—Tobacco (Turkish) has been used with very successful result as an indicator plant to show the fertilizer response of soils under greenhouse conditions. A deficiency in available supply of a nutrient element is evidenced by significant yield reduction and physiol. characteristics of tobacco grown on soils unfertilized with that particular element. No correlation between response and total amts. of N , P_2O_5 , or K_2O was observed on any of the 24 different soil types under investigation. A good correlation existed between P_2O_5 response and amts. of soil P_2O_5 sol. in 0.01 N H_2SO_4 as detd. by the oxalcomolybdate method. K availability was apparently reduced by liming under the condition of these expts. Lime had no beneficial effect except on soils at pH values below 4.8. On soils below pH 4.2 abnormal plant were produced; the injurious effects of this degree of acidity may be assocd. with toxicity of sol. Al or Mn or both. Data given in this paper are incidental to the discussion, and final conclusions should not be attempted until the investigations are completed.

E. F. SNYDER

Nutritional problems of bright tobacco. E. G. MOSS. U. S. Dept. Agr. *J. Am. Soc. Agron.* 21, 137-41(1929).—For the successful production of bright tobacco the phys. and chem. properties of the soil are of first importance. The effects on this tobacco of individual plant nutrients such as N, K_2O , Cl, MgO and their sources are

discussed. The P_2O_5 , CaO and S requirements considered from a practical standpoint are not of special importance at the present time.

Nutritional deficiency studies on tobacco. J. E. McMURTRY, JR. U. S. Dept. Agr. *J. Am. Soc. Agron.* 21, 142-9(1929).— K_2O , MgO, CaO deficiency, the distinction between K_2O deficiency and MgO deficiency and the effects produced when more than one element is deficient are discussed.

Some factors affecting the nicotine content of tobacco. CHARLES W. BACON. S. Dept. of Agr. *J. Am. Soc. Agron.* 21, 159-67(1929).—Topping not only has a profound effect on the nicotine content, but also det. in no small degree the characteristics of the tobacco type itself. The nicotine content also increases during the maturing ripening of the leaves. High N application also increases the nicotine content. The effect of hybridization is also discussed.

A water culture technic for studies in tobacco nutrition. A. B. BEAUMONT AND G. J. LARSISOS. Mass. Agr. Expt. Sta. *J. Am. Soc. Agron.* 21, 150-5(1929).—Four devices and methods of using them are described and devices pictured.

The chemical approach to the study of problems of tobacco fertilization. D. E. HALBY. Pennsylvania State College. *J. Am. Soc. Agron.* 21, 114-7(1929).—The K requirement is one of the most important factors involved in the production of good-quality cigar leaf tobacco. Several well-established facts of a chem. or biochem. nature bearing directly or indirectly on this subject are considered along with a formulation of a chem. interpretation for a no. of unexplainable observations noted by different workers in their investigations dealing with the relationship of K to the plant itself and to the quality of the product.

The lime requirement of acid soils. EUGÈNE ROUX AND CH. BRIOUX. *Compt. rend. acad. agr. France* 15, 185-90(1929).—The lime requirement detd. in the lab. is insufficient for assuring the neutralization of the soil in the field; it should be multiplied by a coeff., probably variable, according to the nature of the soil, and which, for soils of the same nature, appears greater for those which are less acid than for those of an acidity equal or greater than 0.50 per 1000. The coeff. to employ varies between 2 and 3; but to state precisely, it should be necessary to multiply the test in the different regions and on the soils of varied geological nature. Christensen and Jensen arrived at analogous conclusions, and for Danish soils the coeff. by which the lab. lime requirement should be multiplied should be higher than 2.5.

The use of ground limestone (for soil improvement). M. LENGLEN. *Chimie & industrie* 21, 396-400(1929). A discussion of the importance of the nature (phys. structure) of the limestone and its fineness.

Value of lime on Cecil clay loam soil. C. B. WILLIAMS, S. K. JACKSON AND F. T. MEACHAM. N. Carolina Agr. Expt. Sta., *Bull.* 261, 3-26(1928).—As a result of field expts. conducted over a period of 8 yrs., the use of CaO without fertilizer gave the greatest increase in actual % yields with all crops. However, CaO alone did not promote as large increases in actual yields per acre as when combined with fertilizers. In a clover, corn, wheat and cotton rotation, the favorable effect of CaO is attributed to the larger amts. of clover which was produced, and turned under the soil. The use of CaO with P and K is recommended for red clover. For non-leguminous crops, the addn. of N, P and K in moderate amts. to the CaO was profitable. The inference is made that CaO either liberates P_2O_5 and K_2O from the soil for assimilation by the crops, or that the materials supplying these constituents serve to a considerable extent in duplicating some of the functions of CaO in the soil.

Value of lime on Norfolk sandy loam soil. C. B. WILLIAMS, H. B. MANN AND R. E. CURRIN, JR. N. Carolina Agr. Expt. Sta., *Bull.* 262, 3-21(1928).—Results are based on field expts. conducted for 4 yrs. for the purpose of detg. the effect of CaO upon the yield of corn, cotton and peanuts grown in rotation and treated with different amts. and combinations of fertilizers. Contrary to results on the Cecil clay loam soil of the Piedmont section of the state, CaO used alone on corn and cotton grown on the Norfolk sandy loam soil of the Coastal Plain has not usually been found to increase yields. Generally, the increase made from its use as a supplement to different fertilizer mixts. was not sufficient to pay for the cost of its application. In many cases it actually reduced the av. yield of these crops as well as that of peanuts. The use of CaO seemed to be most harmful to the yields of corn, cotton and peanuts under the following fertilizer treatments: with corn when only 2 of the essential constituents of plant food were supplied, and when complete fertilizers, high in N and K_2O , were used; with cotton when only P_2O_5 and K_2O or N and K_2O were supplied, and when complete fertilizers, high in P_2O_5 or K_2O , and when high amts. of complete fertilizer were applied; with peanuts when only P_2O_5 and N or N and K_2O were supplied, and when complete

fertilizers high in P_2O_5 , N and K_2O each were used. These 3 crops grown in -- are rarely benefited enough from applications of CaO to justify its use on this t soil.

C. R. FELL

The changes in soil reaction effected by long-continued fertilizing. BRV THOMAS AND F. J. ELLIOTT. *J. Soc. Chem. Ind.* 48, 51-4T(1929).--The o effects of different fertilizers on the reaction and exchangeable base content of a soil are given in the table.

Fertilizers	Effect on lime status of soil as indicated by measurements of	
	pH	Exchangeable b
Cake fed to sheep	No significant effect	No significant effe
Superphosphate	No significant effect	No significant effe
Dissolved bones	No significant effect	Slight increase
Basic slag	Slight increase	Large increase
Lime	Large increase	Very large increase

J. F. BREWSTER

Recent European fertilizer developments. H. R. SMALLEY. National Fertiliz Assoc., Washington, D. C. *Ind. Eng. Chem.* 21, 375 7(1929).--Comparison of po war (1925-1927) with the pre-war (1913-1914) years shows a marked increase in t consumption of fertilizers in Germany, Holland and France but no increase in Gr Britain. During the period 1913 to 1927 there have been big increases in the use fertilizer N and K_2O , with P_2O_5 making little, if any, gain. A comparison of pre-w and post-war crop yields in Germany and France shows that German yields have declined 14%, while French yields have increased 9%. The disparity in yields attributed to unfavorable weather in Germany in recent years and also to a lack of P_2O_5 . There has been a marked decline in consumption of Chilean NO_3 in Europe, especially in Germany where its use has been practically discontinued, and a tremendous increase in the consumption of synthetic N, largely $(NH_4)_2SO_4$ and cyanamide. There is a decided trend toward the use of complete fertilizers in Europe. In Great Britain 50-60% of the total fertilizer tonnage is factory-mixed, and the use of complete fertilizers is on the increase.

E. F. SNYDER

The determination of potassium in mixed fertilizer. A. STRAIN. Kalifornische Anstalt, Berlin. *Z. anorg. Chem.* 42, 179 82(1929).--The detn. of K in mixed fert in the previous form is bothersome and leads to inaccurate values. By the new meth the addn. and expelling by ignition of NH_4 salts are avoided, the NH_4 of the mixed fertilizer is expelled with caustic soda and the phosphoric acid not pptd. The method is therefore simple, is quickly carried out and yields uniform and accurate K_2O values. This works especially well with the Neubauer analysis.

E. F. SNYDER

Polish phosphates. Fertilizer value of pulverized phosphates from Nierzwiska. PIOTR TERESZCZENKO (with STRZEMINSKI AND HELENA SOWINSKA). *Jagell. Inst. Przemysl Chem.* 11, 81-101(1927).--Pot expts. with oats were performed to study the Nierzwiska phosphates in comparison with Thomas slag and pptd. phosphate. Flours passing 0.16 mm. mesh were used. The Nierzwiska phosphate contained 25.2% P_2O_5 and 21.43% $CaCO_3$. The pots were filled with 1.5 kg. clayey earth of low P_2O_5 and $CaCO_3$ content, showing very nearly neutral reaction. Samples were run without addn. of phosphates, with 0.5, 1, and 2 g. P_2O_5 per pot, with 0.6 g. K_2O and 1 g. N introduced as KNO_3 and NH_4NO_3 , and as K_2SO_4 and $(NH_4)_2SO_4$. Introduction of phosphates to the soil increased the grain yield 2.6-3.3 times and the straw yield 1.5-2.5 times. The phosphate flour used even in very nearly neutral soil equalled the pptd. phosphate and fell only slightly below the slag in its action. Increasing the amt. of the phosphate flour and substituting physiologically acid K, N fertilizer for the neutral increased the crop of grain and its % content of P_2O_5 . Similar effects were also found on the yield of the straw. Assimilation of P_2O_5 with K, N physiologically neutral, was not much lower from the Nierzwiska phosphate than that from the ppt. and the slag, with K, N physiologically acid, it was clearly higher. The active acidity of the soil raised by the addn. of the fertilizer, and was lowered later during the growth of the

ish phosphates. Fertilizer value of phosphate from Nierzwiska and from Lubel. WLADYSLAW VORBRUDY (WITH NIDA AND ZAKRZEWSKI). *Przemysl Chem.* 11, 78-81 (1927).--Flower pot tests with oats showed a decided increase in the yield of grain and

law with both these phosphates in physiologically neutral soil, and still greater yields in physiologically acid soil over yields in soils having no added P_2O_5 . A. C. Z.

Polish phosphates. Possibility of using them in agriculture. JERZY PFANHAUSER. Chem. Lab. Dr. Roman May, Lubon, Poland. *Przemysl Chem.* 11, 101-14(1927).—When phosphates from Kielce, Poland, Florida (hard rock) Gals, Tunis and Constantine are treated with an amt. of H_2SO_4 sufficient to produce dibasic phosphates and also in amounts greater and less than this, an equil. is usually established in which there is 80% and more of monobasic phosphates, and only 10-30% of dibasic phosphates. A period of 2-6 months in general does not make the equil. shift in favor of the dibasic compds. In treating the Polish phosphates (from Kielce), after a time, there can be noticed a diminution of P_2O_5 sol. in 2% citric acid; it amounts to 4% of the original citric-acid sol. P_2O_5 . The other phosphates studied show either more or only a slight diminution in that sense, up to 10%. This diminution in citric-acid sol. P_2O_5 in Polish phosphates can be brought down by mixing with them the foreign phosphates and bone flour. About 45% of the P_2O_5 in the Kielce phosphates is in a form which can be assimilated by plants.

A. C. ZACHLIN

Polish phosphates: their solubility in citric acid. WLADYSLAW VORBRDZ (with STRZEMIENSKI and ZAWADZKI). Jagiello Univ. *Przemysl Chem.* 11, 72-8(1927).—The soly. of Polish phosphates from Niezwiska and from Rachow in 2% citric acid solns. was studied. By increasing the ratio of the solvent to the pulverized phosphate or by prolonging the time of digestion, complete soln. could be effected. A greater concn. of the acid produced the same effect. Thus, these phosphates contain only compds. sol. in dil. citric acid.

A. C. ZACHLIN

Solubility of Polish phosphates in citric acid. ZYGMUNT KOEHLER (and A. SIEGEL). Jagiello Univ. *Przemysl Chem.* 11, 619-24(1927); cf. *C. A.* 22, 4705.—Finely ground (passing 4000 mesh) samples of phosphates from Niezwiska and Kutyska on the Dniestr, Rachow and Nalbow on the Vistula, and Smordwa near Pelcza, Volhyn, were treated with 2% citric acid in ratios of 1:100 and 1:500 parts of sample to soln. These phosphates contain no compds. insol. in 2% citric acid (cf. preceding abstr.).

A. C. ZACHLIN

The production of artificial manure from oats straw under control conditions. P. E. BROWN and F. B. SMITH. Iowa State Coll., Ames, Iowa. *J. Am. Soc. Agron.* 21, 310-22(1929). Composting oats straw with $(NH_4)_2SO_4$ and CaO or $NaNO_3$, or with urea under conditions in the greenhouse for 5 months led to rapid decompn. The application to the straw of 1% or less of N in the form of various nitrogenous materials permitted the production of a good artificial manure after 5 to 9 months' composting under optimum moisture and temp. conditions. With addns. smaller than 1% the treatment with NH_4 , SO_4 and lime seemed to be preferable. The rate of decompn. of various mixts. of straw and chemicals in sand as measured by CO_2 production in the lab. was very rapid when NH_4 , SO_4 with $CaCO_3$ or urea were employed. The other nitrogenous materials were less effective and cyanamide gave a depression. The results of a field expt. indicate that decompn. was more rapid in various compost mixts. than with straw alone. The decompn. in the open, however, was not so rapid as in the greenhouse and there were no great differences among the different composts. The artificial manures produced in the greenhouse, with 2 exceptions, showed as great or greater effects than farm manure on the nitrate content of a virgin Carrington loam. The nitrifying power of the soil was stimulated by practically all of the mixts., but to a less extent than by manure in the early days following treatment, although later the effects were greater than those brought about by manure. In some cases the nitrate-assimilating power of the soil was stimulated by the artificial manures but not to a large extent. The effects, however, were very similar to those brought about by farmyard manure. The production of an artificial manure which will have similar beneficial effects to farm manure seems quite possible. E. F. S.

The economics and synthesis of ammonia for use in fertilizers. I. F. GOODWIN. Queen's Univ., Ontario, Canada. *Can. Chem. Met.* 13, 39-44(1929).—The various synthetic NH_3 processes and catalysts are discussed along with the chief economic factors entering into the manuf., such as, cost of H_2 and N_2 , capital cost of conversion plant, and cost of elec. power. The NH_3 problem has become a H problem, the cost of the raw material accounting for nearly 80% of the manuf. cost. What process to be employed for the synthetic production of NH_3 must be carefully considered in regard to adaptation to local conditions.

E. F. SNYDER

The action of large amounts of nitrogenous fertilizers on the content of protein material in wheat. EUGENE ROUX. Inst. Recherches Agron. *Compt. rend. acad. agr. France* 15, 181-5(1929).—If an insufficiency of N is revealed, in certain cases, by a

depression of the gluten content, the application of N fertilizers, according to the agricultural practice and up to the extreme limits compatible with the sanitary of the yield, remains without appreciable influence on the content of protein mat in wheat.

E. F. SNYDER

Fertilizers for wooded soils. F. A. WYATT AND A. S. WARD. Univ. Alta, monton. *Sci. Agr.* 9, 423-33(1929).—The wooded soil belt constitutes $\frac{1}{3}$ of the area of Alta and neighboring provinces. Mineral plant foods were less abundant in the wooded soils than in the black or brown prairie soils. The first foot of the black soil contained 6 times as much N, twice as much Ca and more Mg than is found in the same depth of the wooded soil. Pot expts showed that where P was applied, a germination was more rapid, plant growth was more vigorous, maturity was hastened, total yield of produce was greater than in controls without added P. Av. crop increa. for fertilizer treatments were P 53, N 16, CaO 29, manure 47, CaO and P 65, and mix fertilizer 63. Virgin wooded soil supported vigorous nitrification, which was still further stimulated by the addn. of CaO. P retarded nitrification. The treatment of CaO plus P showed less nitrates than CaO alone. While P depressed nitrification and the N content of the crops was lower accompanying the P treatment, the crop yields were actually increased because of the P treatment. This indicates that P is not a limiting factor in virgin wooded soil to the same extent as CaO or P.

C. R. FELLERS

Some effects of sub-soil fertilization on the tops and root system of H-109 cane. D. M. WELLER. *Facts About Sugar* 24, 278-82, 288(1929). Expts. were made in boxes contg. a 3-in. layer, 15-19 in. below the surface, of soil treated with (a) $(\text{NH}_4)_2\text{SO}_4$ in the proportion of 500 lb. of N per acre, (b) superphosphate in the proportion of 500 lb. of P_2O_5 to the acre, and (c) K_2SO_4 in the proportion of 4500 lb. of K_2O per acre. Compared with controls, the fertilized soils increased (1) the linear growth of the cane by (a) 63.2%, (b) 68.3%, and (c) 93.7%; (2) the dry wt. of the tops by (a) 78.4%, (b) 111.1%, and (c) 111.0%; and (3) the dry wt. of the roots by (a) 61.6%, (b) 90.5%, and (c) 84.6%. The proportion of total root development in each of the various 8-in. layers and the ratio of tops to roots was not affected materially by the presence or absence of any of the three fertilizers. Chemotropism of the roots to fertilizer was not indicated in any case and the stimulation of the root development extended equally to the fertilized and the unfertilized sides of the box. The increase of root development came from the shoot roots and not from the growth of the seed-piece roots.

M. J. PROFFITT

A study of the influence of fungicides: the toxicity of fungicides. M. F. MARKOVA. *Zap. Leningrad. Selsk. Khok. Inst. (Mem. Inst. Agron. Leningrad)* 3, 270-7(1929). *Expt. Sta. Record* 58, 845. Following a discussion of the chemistry and the toxic properties of fungicides, the author presents data showing the influence of FeSO_4 and of the double salt $(\text{NH}_4)_2\text{SO}_4 \cdot \text{FeSO}_4 \cdot 6\text{H}_2\text{O}$ on the conidia of *Erysiphe graminis* and on the uredospores of *Puccinia dispersa*. The former are more sensitive to a given concn. of the fungicide. The FeSO_4 is more toxic than is the double salt, due supposedly to the fact that the latter contains the $(\text{NH}_4)_2\text{SO}_4$ mol., which antagonizes the FeSO_4 .

Tar-distillate winter washes and the apple capid bug. S. G. JARY. *J. Missouri Agr.* 35, 917-21(1929).—The tar-distillate washes and the various combinations used in these expts. gave only a partial control of the apple capid bug, although spraying was done more thoroughly than would be possible under com. conditions. In order to prevent serious fruit marking a spring spraying would still have been necessary. Two sprayings at an interval of 2 days gave no better control than 1 spraying. The inclusion of caustic soda, either as a preliminary wash or in combination with a tar-distillate wash, did not increase the killing power. When used in combination with a tar-distillate wash, caustic soda has certain advantages. Tarry material which clogs the spraying machinery is thrown out and floats on the surface of the wash. A composite caustic soda and tar-distillate wash (wash No. 4) was much more economical in use than an ordinary tar-distillate wash; on aphids and winter moth cat. puparia it gave an equally good result.

METCALP, C. L.: *Destructive and Useful Insects. Their Habits and Control.* London: McGraw-Hill Pub. Co. 918 pp. 27s. 6d. net.

Fertilizers. EMIL BAUER and FISLER ET SCOLD. Fr. 647,267, Nov. 3, 1927. Molasses residues (vinasses) are mixed with the satm. scums formed in sugar refinery to produce fertilizers. Cf. C. A. 22, 5017, 4709

Fertilizers. SELBI (Soc. d'exploitation de licences de brevets industriels). Fr. 33,696, June 18, 1927. Addn. to 623,227. A dry non hygroscopic fertilizer is obtained by adding 3-4% H_2SO_4 to vinasses from distilleries or sugar factories before adding superphosphate as in the prior patent.

A rational compost for all crops. F. J. B. C. DE TRAY. Belg. 651,201, June 30, 1928. Peat is impregnated with a soln. contg. fertilizing compds. supplying nourishment to the plants and also with catalytic fertilizers, which facilitate assimilation of the nourishing fertilizers. The resulting compost is crushed and then sprinkled with liquid manure.

Phospho-ammonium fertilizer. P. FOCHT and L. DIDIERE. Belg. 351,523, June 30, 1928. A very finely divided natural phosphate is thoroughly kneaded with NH_4Cl and allowed to stand for several days so as to give rise to a certain proportion of sol. phosphate.

Insecticide. WILLIAM H. VOLCK (to Calif. Spray Chemical Co.). U. S. 1,707,465, April 2. A substantially non-volatile viscous mineral oil substantially free from phytocidal ingredients, such as "Oronite crystal oil," is used with a poison such as Pb arsenate and with water as a spray for citrus trees, etc. U. S. 1,707,466 specifies a similar mixt. comprising oil and water emulsified together with an emulsifying ingredient, such as a mixt. of alkali oleate, caseinate and resinate, so that the emulsion reverts to aq. and oily films almost immediately after contact with foliage or other solid surface to which the emulsion is applied in use. U. S. 1,707,467 specifies fungicidal emulsions of a similar oil and water, which may contain a small proportion of S, and an emulsion-stabilizing material. U. S. 1,707,468 specifies the use, in like compns., of an oil having a viscosity between 50 sec. and 350 sec. Saybolt, sp. gr. 0.8-0.9, b. p. 150-400°, substantially free from unsatd. constituents; when agitated, with air at 100° for 284 hrs., it does not produce more than about 25% of substances, which can be removed by 1.84 sp. gr. H_2SO_4 , washing with NaOH and filtering through fuller's earth.

Herbicide. COMPTOIR PARISIEN D'ENGRAIS ET DE PRODUITS CHIMIQUES. 647,104, May 25, 1927. An herbicide contains, e. g., soap 10, heavy oil 25, and or metal borate 5 in 1000 parts of water.

Oil emulsion for spraying plants. HUGH KNIGHT (to Calif. Spray Chemical Co.). U. S. 1,707,469, April 2. A substantially non-volatile oil practically free from phytocidal properties is used with an emulsifier such as oleic acid substantially insol. in water as compared with oil; these substances are agitated with substantially pure water to form an emulsion, the disperse globules of which are visible with a low-power magnifying glass such as one having a magnification of 5 diam. U. S. 1,707,470 sprays contg. similar oil preps. together with a poison such as PhNO_2 or p -dichlorobenzene.

Composition for curing cereal diseases. HANS P. STOLDT. Can. 288,417, Apr. 2, 1929. A compn. for curing cereal (wheat, etc.) diseases comprises an aq. soln. of FeSO_4 67.5, CuSO_4 18.5, NH_4NO_3 13.4 parts and a powder contg. As_2O_3 13.8, FeSO_4 67.5, and CuSO_4 18.5 parts.

Aqueous extract of mowrah seed for killing earth worms. PREMIER OIL EXTRACTING MILLS, LTD., and W. E. WATERHOUSE. Brit. 236,608, Dec. 19, 1927.

Toxic fumigant. EDMUND P. KAMPA and PHILIP N. HYMAN (Kampa to Hyman). U. S. 1,707,727, April 2. A soln. of tetrachlorodinitroethane in a volatile halogenated hydrocarbon solvent of the paraffin series such as ethylene dichloride is used for killing insects, bacteria and vermin.

16—THE FERMENTATION INDUSTRIES

C. N. FREY

Butyric acid fermentation of calcium lactate. V. N. SHATOSHNIKOV AND I. ZAKHAROV. *Trans. Sci. Chem.-Pharm. Inst. (Moscow)* 1927, No. 18, 7-25. A soln. of Ca lactate with phaseolm as the N source was inoculated with a mixt. of bacteria. From a vol. of 3 l. contg. 450 g. Ca lactate only 2 g. of ethyl and propyl alcs. were obtained. From H_2SO_4 soln. the acids were sep'd with ether from Na salts. Two liq. formed; the upper oily layer contained primarily the volatile acids. The quant. of the acids was accomplished by the method of fractional pptn. of the Ag salts; these acids obtained butyric comprised 90.25%, acetic 8.07%. Valeric, formic, capronic acids were present in small amounts. In the lower layer upon extr. with ether acetic and succinic acids were det'd. as 0.3 and 0.4357 g., resp. No trace of lactic acid were found. J. S. J.

The first phases of the chemistry of the dissimilation of the hexoses. H. KLUIJVER and A. P. STRUIJK. *Verslag Akad. Wetenschappen Amsterdam* 37, 70. *Proc. Acad. Sci. Amsterdam* 31, 882-93 (1928); cf. C. A. 22, 1168, 1785. The process was studied of the hexose mono- and diphosphate esters produced after the phosphorylation period, maceration juice mixed with 1 part of a 5% soln. of NaOH and an initial concn. of glucose of 10% being used. In all cases the amt. of the diphosphate ester exceeded to a large degree that of the monophosphate ester.

n. of zymase produces an increased production of hexose-diphosphate ester. It is all probability there are only 2 catalytic actions in the entire process of alc. fermentation, namely, an oxidoreductase- and a phosphatase one. Decrease of concn. of zymase in a fermentation medium increases the formation of Robinson's monophosphate ester. The theories of other investigators are critically discussed. Conclusion: the theory is the only one that connects in a logical way the phenomena of the alc. fermentation and the fermentative dissimilation of the hexoses by the living yeast. J. C. J.

Estimating the yield in the production of unfermented and fermented raisins and raisin vinegar. HEDWICH KRIEGER. *Inst. Gärungsgewerbe, Berlin*. *Essigind.* 23, 80-91 (1929).—An exptl. study giving the essential details of process and results obtained. W. E.

The use of potassium ferrocyanide and phosphoric acid in oenology. *Feuille de Pharm., Alger.* *Ann. (als.)* 22, 94-100 (1929).—A discussion of the advantages and drawbacks of the use of $\text{K}_4\text{Fe}(\text{CN})_6$ for the pptn. of Fe from wines by subsequent pptn. in the finished wine. A. PAFINEAU.

Rationalization in the brewing industry. ALON STADNIK. *Chem. (Russ.)* 4, 39 (1929).—The rationalization in the brewing industry is chiefly manifested by the use of by-products, as malt-gums, malt-lunks and yeast. The utilization of... JAROSLAV F. STARA

The wine industry in Poland. LEONARD BIER. Inst. for Research on Foods and Utensils, Krakow. *Przemysl Chem.* 11, 693-706, 721-5(1927).—It is not possible to duce from unselected fruits wines good enough to compete with the grape wines. As an aid to the industry the establishment of a special trade school, and government support and regulation are recommended.

Stabilizers for wine samples. FONZES-DIACON. *Ann. fals.* 22, 77-8(1929); *J. C. A.* 22, 3950.—It was found that Na benzoate is far from being as effective as salicylic acid for preserving wine samples from acidification by *Mycoderma aceti*.

A. C. ZACHLIN
A. PAPINEAU-COUTURE

The resistance of beer to infection. ERN. BEKAERT. *Bull. assoc. étres inst. sup. fermentations Gand* 30, 103-14(1929).—An address discussing the chief causes of infection of beer and the factors by means of which it can be prevented.

Synthesis of optically active compounds by means of yeast. I. Synthesis of *L*-aspartic acid from fumaric acid. YUSEKE SUMIKI. Tokyo Imp. Univ. *Bull. Jap. Soc. Ferment* 23, 33-41(1928).—*L*-Aspartic acid was synthesized as follows: To Na fumarate is added twice the quantity NH_4Cl and the resulting mixt. are added beer yeast, Clark and Lubb's buffer mixt. of pH 6.8-7.0 and PhMe . The mixt. is kept at $37-40^\circ$ under reduced pressure and is shaken once a day. Max. yield is 75.59%. Some succinic acid was also obtained; this indicates the possibility of the conversion of fumaric acid through succinic acid besides the direct conversion. It is also possible that succinic acid is formed from fumaric acid through aspartic acid.

Lactic acid. I. G. FARBENFABR. A. G. Fr. 647,515, Jan. 20, 1928. See *Brit.* 230,464 (*C. A.* 23, 849).

Mash tub for treating massecuite, etc. A. ROLZ. *Brit.* 297,054, Sept. 13, 1927. Structural features are specified relating to supply of liquid to the tub through perforated branched pipes.

17—PHARMACEUTICAL CHEMISTRY

W. O. EMERY

Microchemical reactions for cinchonine. M. W. ENAAR. *Pharm. Werkblad* 66, 250-3(1929).—The delicacy of various reactions in terms of min. concn. of alkaloid and min. amt. detectable are: pptn. of free base, 1:1000, 2 mg.; K_2CrO_4 , 1:500, 10 mg.; $\text{K}_3\text{Fe}(\text{CN})_6$, 1:1000, 5 mg.; $\text{K}_3\text{Fe}(\text{CN})_6$, 1:1000, 5 mg.; gentisic acid, 1:2000, 1 mg.; NH_4SCN , 1:300, 30 mg.

A. W. DOX

Decomposition of chloroform under the action of light and oxygen, and its conservation. KURT BODENBONN. Univ. Berlin. *Monatsh. Chem.* 44, 351-3(1929).—Exception is taken to the findings of Oberhard (cf. *C. A.* 23, 2245) on the conservation of anesthetic CHCl_3 . The conditions affecting the keeping qualities of this drug are far more complicated than those assumed by Oberhard. It is shown experimentally that alkali and H_2O promote decomposition, markedly, probably by favoring the process: $\text{CHCl}_3 \rightarrow \text{CCl}_2 + \text{HCl}$, which is, however, not dependent solely on the presence of those 2 im-

purities, since pure CHCl_3 is itself subject to decompn. The slight increase in decompn. through presence of I (0.2%) is probably due to its photochem. influence as sensitizer. Of all the substances tested EtOH (2%) proved the best stabilizer. CHCl_3 thus and kept in the dark in fully filled and dark glass bottles remained practically changed for indefinite periods. W. O. E.

Characterization of homeopathic drugs. H. NEUGEBAUER. *Apoth. Ztg.* 44, 381-4 (1929); cf. C. A. 22, 4718.—Detailed procedures are indicated for the evaluation apomorphine-HCl, morphine-HCl, codeine phosphate, HgCl_2 , $\text{Hg}(\text{OCN})_2$, Hg_2Cl_2 and HgI, in their several potencies. W. O. E.

Fusel oil test of the D. A.-B. 6 for absolute alcohol and spirit. K. R. DIETRICH AND H. JEGLIŃSKI. *Pharm. Ztg.* 74, 436-7 (1929).—A commentary on the official Ger. method. W. O. E.

Dihydrated sodium phosphate. E. RIPP. *Apoth. Ztg.* 44, 399-400 (1929).—This salt, official in the Dutch and Russian pharmacopoeias, has certain advantages over the other two salts having 7 and 12 mols. H_2O of crystal, resp., notably in the prepn. of buffer solns. The salt is conveniently prepd. by heating a weighed quantity of $\text{Na}_2\text{HPO}_4 \cdot 12\text{H}_2\text{O}$ on the H_2O bath under const. stirring until the loss in wt. is exactly one-half the original. The product is kept in tightly stoppered bottles. W. O. E.

Examination of liquor cresoli saponatus D. A.-B. 6. WALTER MEYER. *Chem.-Ztg.* 53, 43 (1929).—For the new pharmacopoeia (*Arzneibuch*) the following test is suggested for Liquor Cresoli saponatus: Mix 3 parts of the sample in a beaker with 7 parts boiling H_2O and stir with glass rod. No offensive odor of animal oils should be immediately or even after the lapse of 3 min. perceptible. There should on the contrary be a pure cresol odor along with the typical odor of caustic alkali liquor. W. O. E.

Misjudgment and adulteration of vegetable drugs. EDUARD SKARNITZL. *Heil- und Gewürz-Pflanzen* 11, 171-7 (1929).—Many examples are cited in the adulteration and misjudgment of crude drugs. W. O. E.

A few compositions having flowery odors. OTTO GERHARDT. *Parfumerie moderne* 22, 91-5 (1929).—Formulas are given for acacia, "cassie" (*Cassia fernexiana* Willd.), and cyclamen perfumes. A. PAPINEAU-COUTURE.

Estimation of morphine in powdered opium, opium extract and its tinctures. THEODOR BÖHM. *Pharm. Monatsh.* 10, 34-5 (1929); cf. C. A. 23, 1409.—An address dealing principally with methods of the Ger. Pharm. W. O. E.

Curative sera and their preparation. A. MÖSSY. *Tetartzi Hochschule, Budapest Pharm. Monatsh.* 10, 36 (1929).—An address briefly descriptive of the procedures followed in the prepn. of sera from specially immunized animals, as horses, cattle, sheep and swine. W. O. E.

Notes on the Mexican Pharmacopoeia V. H. ALFARO. *Pharm. Ztg.* 74, 35-350-3 (1929).—A commentary. W. O. E.

Pharmacochemical results in the examination of domestic drug plants. I. KROGGER. *Pharm. Ztg.* 74, 364-6 (1929); cf. C. A. 22, 1213.—Exts. made with parts H_2O and 7 parts EtOH yielded values as follows.

	d	Dry residue	Ash
Ext. Anagallis arvensis fluid	1.075	27.20%	3.40%
Ext. Erythraee centaurei fluid	1.065	22.75%	1.05%
Ext. Eupatorii cannabini fluid	1.018	12.25%	1.55%
Ext. Euphrasiae officinalis fluid	1.079	21.00%	2.35%
Ext. Meliloti officinalis fluid	1.122	38.05%	3.60%
Ext. Plantaginis lanceolatae fluid	1.103	31.20%	3.70%
Ext. Spiraeae ulmariae fluid	1.009	15.90%	2.15%
Ext. Stipitis cerasorum fluid	1.039	16.30%	2.30%
Ext. Vaccinii myrtilli fluid	1.029	13.65%	1.00%

The several exts. are discussed at some length, notably with respect to their odor, taste and behavior when treated with H_2O , EtOH, and other reagents like FeCl₃, tannic acid, Mayer's, Lugol soln., Fehling's, $\text{Pb}(\text{OAc})_2$, etc. W. O. E.

Estimation of the camphor content of oleum camphoratum. LAJOS DAVID. *Univ. Josef-Jun., Szeged. Pharm. Ztg.* 74, 437-8 (1929).—See C. A. 23, 1990. W. O. E.

Color reactions of morphine. LAD. FERRER. *Parmany-Peter-Univ., Budapest Pharm. Zentralhalle* 70, 165-7 (1929).—See C. A. 23, 1990. W. O. E.

Perfumes, essential oils and cosmetics in the world's economy. KARL LÖFF. *Hamburg. Pharm. Zentralhalle* 70, 183-5 (1929).—An economic study showing the extent of production and marketing of perfume requisites in European countries. W. O. E.

termination of iodine in thyroid glands. L. U. VAN DER BERG. *Int. Pharm.* 17; *Quart. J. Pharm.* 1, 85.—Cameron and Carmichael have shown that the titration of thyroid glands can be accomplished by detn. of the percent content of iodine. The matter must be completely destroyed, and org. I must be converted into inorganic. The best method is to destroy org. matter by use of an oxidizing agent. Excess reagent is then removed, and the I liberated in acid soln. and titrated. This method is preferred to the alternative, involving calcination with alkali, because (1) destruction of org. matter is complete; (2) oxidation to iodate is easier than reduction to iodide; and (3) the titration takes place in the reaction liquid, thus preventing loss. The method of the U. S. P. is recommended. W. O. F.

Quinisol is a valuable antiseptic, since it is a phenol. It has recently been found serviceable in the treatment of fungoid infections of the skin, in the form of the following lotion and cream: (1) quinisol 0.5 to 1, alc. (95%) 50, glycerol 20, boiled H₂O 100. Dissolve the quinisol in the H₂O, then add the alc. and glycerol; (2) quinisol 0.5, and boiled H₂O 5, anhyd. wool fat 25, vaseline 70. Dissolve the quinisol in the H₂O, incorporate with the wool fat, then mix in the vaseline. Quinisol is also put on the market in the form of "Dippol," which consists of sheets of cardboard paper impregnated with quinisol. The sheet is macerated in the prescribed amt. of H₂O. The paper becomes white and the water yellow when soln. is complete. W. O. E.

Digitalis leaves of the new pharmacopeias. MEULENHOF. *Int. Pharm. Fed.* 1927; *Quart. J. Pharm.* 1, 120-1. Am., Ger. and Dutch pharmacopeias now introduce a biol. standardization instead of attempting to obtain av. activity by limiting the period of collection of the leaves. The prepn. of a 0.5% aq. infusion ensures complete extr., and the cat method of Hatcher is recommended for the assay. Dutch plants vary greatly in activity, but the influence of drying between the temps. of 15° and 100° is of little importance. A mean temp. of 53° is recommended as the optimum for drying. The leaves retain their activity for several yrs. even when kept under bad conditions. An inquiry into the choice of extr. media, both for assay and galenical prepn., afforded evidence that both H₂O and strong alc. completely exhausted the leaves. Of the galenicals, the acetum is inferior to tincture and infusion. The Liquor Digitalis of the latest Dutch Pharm. is suitable for injection, and its use is recommended in preference to proprietary articles. In a short reference to *Sirophanthus*, chem. assay is advocated after a comparison of chem. and physiol. methods. Finally, it is reported that digitalis preps. decrease in strength when in contact with strong alc.; the effect is sometimes marked, but not const., and depends on factors which at present are unknown. W. O. E.

Presence of magnesium ammonium phosphate in commercial licorice extract. A. JERNSTAD. *Norge Apot. Tidsskr.* 54, 1927; *Quart. J. Pharm.* 1, 121-2.—A Swiss wholesale house recently received a consignment of com. licorice ext., which contained a considerable amt. of a substance insol. in H₂O. This consisted of a cryst. shining powder, in which black specks of extractive matter were scattered. J. found that the cryst. residue was MgNH₄ phosphate. This salt is probably formed in the crude licorice "juice." It is known that the glycyrrhizin thereof occurs as an NH₄ compd. and that Mg and phosphates are present. Probably its occurrence in crude "block licorice" has been hitherto overlooked, since the insol. matter which it contains has not been carefully examd. W. O. E.

New constituents of East Indian lemongrass oil. F. ELZE. *Riechstoffind.* 4, 22-3 (1929).—The oil obtained after removal of the citral gave on refractionation methylheptenol, nerol and farnesol. W. O. E.

Apricot oil as a substitute for almond oil. G. KOGAN. *Chem. Umschau Fette, Oele, Wachs Harze* 36, 83-3 (1929).—K.'s observations lead him to the following conclusions: The general trade is offering only apricot oil, for which the proper name would be oleum Armeniacae. Its phys. consts. lie very close to those of true almond oil and its low acid no. (not above 2.0) permits its use for subcutaneous injection; its acid no. is lower than that of almond oil. The German Pharm. should, under "oleum Persicarium," which includes apricot oil, lower the max. acid no. to 2.0 and require that no alk. ash be left on ignition. P. ESCHER.

Study of commercial lecithins and specialties with lecithin as base. I. JACQUES SONOL. *Rev. faculté chim. quim. Univ. La Plata* 4, No. 2, 95-110 (1927); cf. C. A. 23, 237.—Lecithin is C₂H₅(OR)(OR')OP(O)(OH)OC₂H₅N(OH)Me₃, where R and R' may

be palmitic, oleic or stearic acid radicals and may be the same or may differ from each other. No agreement is yet reached upon the amount in various parts of the body. The brain may contain 11-16%, yolk of egg 6-12%, cardiac muscle 12.5%. Methods for prep. lecithin of Diakonow and Hoppe-Seyler, Gibson, Wart, B. Thomas and Fischer, S. believes that lecithin is lost in the ether or acetone used. Methods of Smith, Strecker, Bergell, MacLean and Lami are reviewed. The author's method, for which he claims good solvent recovery, excellent and perfect stability: The tissue is dried over acetone, and then extd. for 12 three times, at 50°, with abs. EtOH. This is removed *in vacuo* and before the yellow is decanted from the red liquid below it. It is now concd. *in vacuo* and treated with a little Et₂O. The lecithin is pptd. with acetone thrice and dried to remove traces of the latter. Lecithins should be sol. in abs. EtOH, CHCl₃, Et₂O, olive oil, liquid vaseline and other solvents. The commercial products are yellow to brown and become rancid in air; some are neutral, others acid. The purest specimens contain cholesterol and other substances.

S. L. B. HERTON

Hemlock and coniine. A. R. VALENTINI. *Boll. chim. farm.* 68, 155-9 (1929).—The pharmacol. effect and the therapeutic value of hemlock and coniine and the chem. properties of coniine are described.

G. SCHWACH

Preparation of oil-soluble bismuth salts, hexahydrobenzoate and camphocarboxylate. M. PICON. *J. pharm. chim.* 8, 206-11 (1928); cf. C. A. 23, 2215.—These salts cannot be prepd. pure, *i. e.*, free from Na by the glycerol method of double decomp. (C. A. 21, 2359). To prep. *Bi hexahydrobenzoate*, (C₆H₁₀O₆)₂Bi, (A), add to C₆H₁₀CO₂H the theoretical quantity of yellow Bi₂O₃ to form the neutral salt, heat the mixt. on the boiling water bath with mech. stirring until the mass is a white solid. Dissolve the powd. mass in warm C₆H₆, filter, distil off the solvent and remove adhering traces by heating *in vacuo* on the water bath. A is a faintly yellow, amorphous, transparent mass, insol. in H₂O, sol. in org. O-free solvents, but insol. in solvents contg. O (excepting oils). The latter, *e. g.*, MeOH, cause disoccn. of A with formation of BiO.C₆H₁₀O₆. The same compd. is formed when H₂O acts on the C₆H₆ soln. of A. A absorbs H₂O from the air, becoming viscous and transparent, then opaque. *Neutral Bi camphocarboxylate*, (C₁₁H₁₈O₄)₂Bi, (B), is prepd. similarly to A. Heat camphocarboxylic acid with the equiv. quantity of Bi₂O₃, adding, however, a little H₂O to hasten the reaction. Cool and decant the H₂O, then treat the mass with C₆H₆ as with A. Distn. of the solvent will remove the rest of the H₂O. B is faintly yellow, amorphous, sol. in all org. solvents including those contg. O, and is insol. in H₂O; this has no action on it in C₆H₆ soln. Soly. in oil of A is 0.05 g. Bi per cc. or 12.5% of the salt; soly. of B is 0.01 g. Bi per cc. or 33% of the salt, but as this soln. is too viscous, a soln. of 0.05 g. Bi per cc. is preferred for injection. Oily solns. of A, like A itself, are very hygroscopic, and solns. of B are permanent. The soly. of A and B in oil is caused by the satd. soln. of the constituent acids. Elimination of Bi after intramuscular injection of A or B in oil-soln. is much more rapid than that of oily suspension of inorg. Bi salts, *e. g.*, BiCl₃. Bi carbonate. •

S. WALDRON

Derivatives of *p*-methoxycinnamic acid (FOOTE) 10. Hypoglucemia producing substances. 1. Synthesis of certain guanidine derivatives (KUMAGAI, *et al.* 10). 2. Oxidation of commercial carboic acid (KOGAN) 7. Extraction of oil from liver (U. S. pat. 647,941) 27. Condensation products of indene with phenols [for disinfectants (Brit. pat. 297,075) 18. Toxic fumigant (U. S. 1,707,727) 15. Soap [for treating rheumatism] (Ger. pat. 472,440) 27. Purifying oils (Ger. pat. 472,212) 27.

Calcium gluconate solutions. CHEN. FAB. VORM. SANDOR. Ger. 472,346. Nov. 27, 1926. Stable supernatd. solns. of Ca gluconate for medical use are prepd. by dissolving a hot, sterile soln. of the salt into ampoules, hermetically sealing the ampoules, and heating them in steam at intervals until crystn. no longer occurs on cooling. The solns. may be injected intramuscularly without inflaming the tissues.

Derivative of isobutylallylbarbituric acid. CHEMISCHES FABRIK VORM. SANDOR. Fr. 647,718, June 3, 1927. A compd. having therapeutic properties is obtained by melting together isobutylallylbarbituric acid and 1-phenyl-2,2-dimethyl-4-dimethylamino-5-pyrazolone. The purified compd. m. 83-85°.

Hypnotic and sedative solution. WALTER KNOFF (to Winthrop Chem. Co.) U. S. 1,707,863, April 2. Therapeutic compds. such as allylrotylbarbituric acid are dissolved in a mixt. of acetamide and ethylurethane and water, or in a similar mixed solvent.

Antiseptic anesthetic compounds. RICHARD H. VOLWILER and DONALD L. TABERN

Abbott Laboratories). U. S. 1,708,712, April 9. Butyl *p*-aminobenzoate is combined with halogenated aromatic sulfonic acids contg. a phenolic OH group (suitably by mixing solns. of the reacting substances and sepg. the crystals which form) to obtain products suitable for local anesthetic and antiseptic effect. Examples are given of the production of butyl aminobenzoate salt of 2,6-diiodophenol-4-sulfonic acid, m. (decompn.) 200° and of the corresponding compds. of 2,6-dibromophenol-4-sulfonic acid, m. 216–18° and 7-iodo-8-hydroxyquinoline-5-sulfonic acid, m. 235–40°.

Antiseptics. I. G. FARHENIND, A.-G. Brit. 297,074, June 14, 1927. A phenol ether or deriv. of such an ether without free phenolic groups is used in disinfecting for various pharmaceutical purposes or for preserving foods; e. g., marmalade may be preserved with an addn. of 0.15% Na anisate; acetanisidine is used in a foot-dusting powder with ZnO, wheat starch and talc; a disinfecting hair-wash comprises pyrocatechol dimethyl ether in alc. soln.

Substances which can impart activated nourishing properties to foods and drugs. G. DUBOIS, Belg. 350,983, June 30, 1928. Yeast and bacteria from the stomachic flora are isolated, cultivated and dried in order to obtain the digestive enzymes and diastases, and the product is combined with vegetable diastases developed by the action of ultra-violet light on cereal germs.

Capsuled material for heating body tissues. JOHN G. HOMAN, U. S. 1,707,762, April 2. A capsule suitable for rectal treatment or similar uses comprises a casing which may be formed of a gelatin compn. contg. a mixt. of Mg and a metallic oxide such as Cu oxide together with cacao butter or other suitable medicating vehicle.

Tuberculosis antibodies. ROLF GRIESBACH, Ger. 472,080, Mar. 29, 1927. Specific antibodies for tubercle bacilli are prepd. in the following way. A guinea pig or other suitable animal is inoculated 3 times, at intervals of 9 days, with a glycerol emulsion of virulent living tubercle bacilli, the inoculations being performed percutaneously on a depilated part of the abdominal skin. Ten days after the 3rd inoculation, the suprarenal capsules are removed, cut up, and extd. with aq. glycerol in a darkened vessel. The ext. is stored in a cool place, with frequent shaking, and after 3 days is heated on the water bath for 20 mins., centrifuged, and filtered. Powd. cryst. thymol is then added.

Treating bacteriolytic products. KALLE & CO. A.-G. (G. Deycke, inventor). Ger. 472,221, Apr. 1, 1924. The toxic components are isolated after bacteriolysis, particularly of tubercle bacilli, by treating the filtrate with CCl_3COOH or tannin. The toxic components ppt. and are sepd. and redissolved.

Composition for pyorrhea treatment. LEONARD E. HARRIMAN, Can. 287,613, Mar. 5, 1929. A compn. for the treatment of pyorrhea consists of lanolin 116.96 g., 9% NaCl soln., 4.32 g., iodophenolsulfonic acid 7.85 g. (or AgI), and BiONO_3 350.87 g.

Face powder. SIDNEY PEEKER, to Crystal Chemical Co., U. S. 1,707,684, April 2. A powder such as talc, MgCO_3 , ZnO and Zn stearate is mixed with a small quantity of olive oil to form a coating on the particles of the powder which give them better adhesive properties when applied to the skin (although leaving the powder dry to the touch).

18—ACIDS, ALKALIES, SALTS AND SUNDRIES

E. M. SYMMES

New system for large-scale manufacture of sulfuric acid. HUMBERTO J. PAOLI, *En. facultad cienc. quim.* (Univ. La Plata) 4, 111 23(1927).—The Mills-Packard towers, truncated in shape, externally water cooled, and exposed to the weather, have a low first cost and low lead consumption. The Gaillard tower walls are cooled and protected by specially distributed dil. acid. The resp. yields are 18–21 kg. and 15.5 kg. of acid per cu. m. Later improvements are (1) alteration in the shape of the Pb chamber to obtain better wall washing; (2) centrifugal pumps are replaced by pulsometers; (3) natural draft S furnaces have been replaced by mechanically rotated ones with artificial draft, charged automatically; (4) the Glover-Suntil, vertically divided tower has been adopted. P. obtains 24 kg. per cu. m. 52 B \acute{e} acid, with a HNO_3 consumption of 3%, with 3 men per 24 hrs. One section of the Glover tower denitrates and the other concentrates to 64 B \acute{e} . Less land is required and the lead work is completely preserved.

S. L. B. ETHERTON

Preparation and industrial use of solid carbonic acid. R. PLANK, *Z. Ver. deut. Ing.* 73, 221–4(1929).—A review of American practice in the prepn. and use of solid CO_2 or "dry ice."

W. C. EBAUGH

Dry ice, the new refrigerating and preserving agent and its production. A. STEN-SALMONY. *Chem.-Tech. Rundschau* 44, 275(1929).—The characteristics of solid CO_2 are described, as well as the method of its production by the Carba Akt.-of Bern. This method consists in chilling at a pressure of over 5 atm. and yields a of sp. gr. 1.4–0.5. This is contrasted with other processes which yield first a somewhat spongy CO_2 -snow, which must be further compressed.

Purification of hydrogen [for use in the manufacture of ammonia]. G. I. L. DES YLOUSS. *Science ind.* 11, 53(1927).—Liquefiable impurities, e. g., H_2S and carbonyl sulfide, and the last traces of CO are removed from H_2 recovered from water by treatment with liquid N under pressure at -180° .

Lead sulfate. H. SCHRADER. *Farben-Ztg.* 34, 268-9(1928).— PbSO_4 is produced as a by-product of the manuf. of Al acetate for waterproofing tarpaulins, etc. It may be used as a starting point for chrome yellow, first being converted into carbonate and then treated with $\text{K}_2\text{Cr}_2\text{O}_7$ and H_2SO_4 ; the process has some advantage in the cheapness of Pb as sulfate. Other variants of the method are: conversion of PbCO_3 into basic nitrate or chloride by treatment with acid and double decomposition with alkali dichromate; decomposition of the PbSO_4 with NaOH or CaO and treatment of the basic sulfate with dichromate; production of basic sulfate by treatment of the normal salt with dilute HOAc and then proceeding as in the previous method.

Method of ascertaining the origin of Guggenheim saltpeter. JAN HAMPL. *Chem. Obsor.* 4, 33-4(1929).—The detn. of I can easily be misleading, as not every lot of Guggenheim saltpeter shows the I reaction. Guggenheim saltpeter contains more Na_2SO_4 than synthetic saltpeter, whereas the amt. of NaCl present cannot serve as a criterion. Furthermore, in the case of Guggenheim saltpeter the sum of the refraction index and quantity of NaNO_3 (calcd. from the amt. of N found) is less than 100, as it is in the case of synthetic saltpeter.

Activated carbons. R. G. W. FARNELL. British Sugar Processes, Ltd. *South African Chem. Ind.* 12, 21-4(1929).—A survey of the industrial uses of activated carbons.

Activated charcoals. FRAN PODREKINIK. *Inst. du Vin. Bull. int. vin* No. 5 78-82(Feb., 1929).—A review of the theory of activated charcoals, their processes of manuf. and uses.

Charcoal as an adsorbent. M. M. DUBININ. *J. Russ. Phys. Chem. Soc.* 6 850-60(1928); *cf. C. A.* 23, 1547.— HNO_3 , NH_4 , K and Ba nitrates, chloric acid and NaOH solns. remove adsorbed Cl ions almost quantitatively from charcoal. This is not due to preferential adsorption, for AcOH , which is more strongly adsorbed than HNO_3 , does not show this effect. A very highly adsorbent charcoal, contg. practically no adsorbed acid, is prepd. by heating ordinary charcoal at 800° for 1 hr., and then wetting it with 4 N HNO_3 . After 3-4 hrs. excess of HNO_3 is removed by filtration, and the charcoal boiled for 2 hrs. with 2 l. of water. The product is dried and heated in the blow-pipe for half an hr. in a closed porcelain crucible, when the adsorbed HNO_3 is decomposed with oxidation of part of the charcoal. The resulting product strongly adsorbs acid and neutral salts, but not alkalis.

Asbestos in 1927. OLIVER BOWEN AND B. H. STODDARD. *Bur. Mines, Mineral Resources of the U. S. 1927*, Pt. II, 200-311 (preprint No. 25, published February 1929).

Phosphate rock in 1927. H. L. JOHNSON. *Bur. Mines, Mineral Resources of the U. S. 1927*, Pt. II, 312-26 (preprint No. 26, published March 11, 1929).

Flotation tests on phosphorite from Esthonia. JAAK KIVSK. *Sitil. Akad. Form. Ges. Univ. Tartu* 35, 71-9(1928).—Preliminary tests were made with fatty acids as flotation reagents and with shale oil fractions $170-250^\circ$ as a stabilizer. The best results were obtained with train oil acid, at the ratio of 1% of the wt. of oil in the absence of a stabilizer, or at the ratio of 1/2% and using shale oil fraction 170-250°, in neutral or slightly alk. soln.; however, such impurities as CaCO_3 , CaSO_4 , etc., would also be floated under these conditions.

The limestone resources of the Pontiac-Fairbury region. J. E. LAMON. *Ill. State Geol. Survey, Rept. of Investigations No. 17*, 7-27(1929).—There are tracts some probably 200 acres or more in extent, underlain by limestone. A 200-acre tract underlain by 11 ft. of limestone would contain about 3,500,000 cu. yd. or about 2,000,000 tons of limestone. Many of these tracts are located on or near a railroad. The overburden varies from 1 to 5 ft. and probably averages about 3 ft. The limestone is suitable for agricultural limestone, macadam roads, portland cement, portland road ballast, flux and CaO . The outstanding use for which the limestone is now employed is the manuf. of portland cement which is favored by the presence of a suitable

and assocd. clay, shale and argillaceous limestone, which provide the necessary materials. Fuel can probably be obtained locally and local labor is regarded as

H. C. PARISH

Manufacture of synthetic bleaching clays. M. NEKRITCH. *Z. anorg. allgem. Chem.* 177, 86-90(1928).—Lab. tests were made to demonstrate that a product similar to bentonites is formed, when sodium silicate and $Al_2(SO_4)_3$ react. The product gains considerable cryst. material, purifies mineral and vegetable oils; the Al_2O_3 content is not completely sol. in acids; and the adsorption of gases varies inversely with the temp. The formula $Al_2O_3 \cdot 7SiO_2 \cdot nH_2O$ is assigned to the product.

T. P. KELLER

The thermal decomposition of NH_3 on Fe catalysts (KUNSMAN) 2. Generalities on the mechanical preparation of minerals (CHARRIN) 13. The gauze catalyst in NH_3 oxidation (PERLEY, VARRELL) 2. Condensation products of urea and CH_2O of high molecular weight (SCHEIBLER, *et al.*) 10. Drying apparatus for casein and other powdered substances (Fr. pat. 647,911) 1. Drying apparatus for casein and the like (Fr. pat. 33,567) 1. Bubble cap absorption tower suitable for absorption of N oxides (U. S. pat. 1,708,985) 1.

Nitric and sulfuric acids. I. G. FARNENIND. A. G. Fr. 647,744, Dec. 17, 1927. HNO_3 and H_2SO_4 and their salts are prepd. by passing mixts. of NH_3 , volatile compds. of S and cyanogen compds. such as obtained from the liquids used for washing industrial gases, after adding O or gases contg. it, over catalysts at a high temp. to obtain oxides of N and S. Suitable catalysts are Pt gauze or a mixt. of Ni, Fe and Cu.

Sulfuric acid. H. PETERSEN to Soc. générale métallurgique de Hoboken). Brit. 206,602, Sept. 3, 1927. In the lead chamber process of H_2SO_4 manuf., reaction towers (preferably packed) are inserted between the Glover tower and the first chamber or between the chambers, and are irrigated with H_2SO_4 rich in N oxides or with a large quantity of H_2SO_4 contg. N oxides such that the acid discharged from the towers still contains N oxides at least equal to 0.5% (called as HNO_3 of 36° Bé. The acid is introduced at a temp. not above 35°.

Sulfuric acid. METALLURGES A. C. Ger. 472,420, Dec. 8, 1925. Addn. to 378,610. See Brit. 202,397 (C. A. 21, 3715).

Hydrocyanic acid and acetylene. SOC. ANON. POUR L'IND. CHIM. A BAILE and H. ANDRIESSENS. Brit. 206,355, Aug. 29, 1927. Gaseous mixts. contg. CH_4 (or petroleum vapors) and N are treated in a flaming arc to produce HCN and C_2H_2 ; and the gases leaving the arc are treated to sep. the HCN and at least a part of the C_2H_2 before being returned to the arc. A gas circuit as described in Brit. 195,239 (C. A. 17, 3555) may be used and the HCN may be absorbed in alkali and the C_2H_2 by water under pressure.

Acid-resisting coatings. I. G. FARNENIND A. G. Fr. 647,588, Jan. 20, 1928. Containers are covered with molten Si or alloys of Si contg. Fe, Cu, Mn, Cr or W.

Ammonia synthesis. RALPH S. RICHARDSON to Nitrogen Engineering Corp.) U. S. 1,707,417, April 2. Incoming gases at high temp. and pressure are passed through the catalyst in heat-exchange contiguity but out of direct contact, in one direction, and then, in the same direction, in actual contact with the catalyst. Cf. C. A. 23, 1908.

Heat-interchange apparatus suitable for use in ammonia synthesis. FRANCIS H. BRAMWELL (to Atmospheric Nitrogen Corp.). U. S. 1,708,887, April 9.

Cyanides. I. G. FARNENIND A. G. Fr. 647,619, Jan. 23, 1928. Cyanates are reduced to cyanides by reducing gases such as H or CO at a temp. of 700-750°.

Pure sulfide. I. G. FARNENIND A. G. Ger. 471,776, Oct. 1, 1926. Addn. to Ger. 431,253. The sulfide lye purified by salt in the manner of the prior patent is concd. by degrees in vacuo.

Lead salts. STANLEY C. SMITH. Fr. 647,761, Jan. 4, 1928. See Can. 283,213 (C. A. 22, 4271).

Separating alkali or alkaline earth salts. SALZWERK HEILBRONN A. G. and LEUWIG KATNER. Ger. 472,100, Oct. 16, 1925. Individual alkali or alk. earth salts are sep'd. from a mixt. of such salts by fractional crystn. from the fused mixt. The melt is allowed to cool slowly in an insulated bath and the salt which seps. first is removed by suitable means. The sepn. of NaCl from its mixt. with sulfates and from crude K salts is mentioned.

Ammonium phosphate. CHEMICAL PRODUCTS CO. Brit. 207,009, June 10, 1927. Phosphate rock is treated with NH_4HSO_4 soln. to produce NH_4 phosphate soln. contg. some $(NH_4)_2SO_4$ and H_3PO_4 . The pptd. $CaSO_4$ is mixed with $(NH_4)_2CO_3$ soln. or with

NH_4 soln. into which CO_2 is passed to form CaCO_3 and $(\text{NH}_4)_2\text{SO}_4$ soln. which is converted into NH_4HSO_4 . The phosphate soln. is treated with NH_3 to form P which is crystd. and heated to form NH_3 and mono- and di- NH_4 phosphates.

Calcium nitrate; alumina; phosphorus; and silica. I. G. FARBERMAN. A. G. Brit. 296,832, June 16, 1927. A raw phosphate is fused with coaly material and minous material such as bauxite, kaolin, clay or loam to distil off P , and the slag is converted and sepd. into $\text{Ca}(\text{NO}_3)_2$, alumina and silica. The process is preferably so conducted that Fe present is reduced and tapped out as a "phosph" pig iron and the addn. of bauxite and other materials is so regulated that the slag retained contains 45-60% CaO , 10-40% oxides of Fe and Al and 30-10% silica; the slag disintegrates readily on cooling and is readily decomposed by acids. The is treated with HNO_3 to dissolve the Ca and Al and the silica is sepd. and may be as an absorbent or insulating material or for agricultural purposes. Al and Fe are pptd. from the nitrate soln. by use of milk of lime or CaCO_3 , preferably in the presence of small quantities of substances such as brown coal-tar oils, coal-tar oils, or tetrahydronaphthalene to reduce the bulk of the ppt. From the remaining soln. the $\text{Ca}(\text{NO}_3)_2$ is recovered in solid form. A Moroccan phosphate may be used as raw material.

Copper sulfate. H. LAWARR. Belg. 351,876, July 31, 1928. Cu is treated with an aq. soln. of H_2SO_4 and HNO_3 , the proportion of HNO_3 being such that the amount of NO_2 formed is not in excess of the amount that is sol. in the soln. An app. is described.

Nickel and cobalt carbonyls. I. G. FARBERMAN. A. G. Brit. 296,558, Sept. 5, 1927. Ni and Co carbonyls are made by the action of CO on the corresponding metals prepd. from NH_3 compds. such as are obtained by leaching ores with ammoniacal solns. The pure metals may be obtained from the resulting carbonyls.

Osmotic purification of caustic soda. LEONARDO CERINI. Fr. 33,608, May 21, 1927. Addn. to 616,821. The arrangement of diaphragms is given.

Sodium silicate. SIMON TARIK. Fr. 647,132, May 30, 1927. The soda lys. obtained as a residue in the manuf. of paper pulp from maritime pine or other woods is heated with hydrated SiO_2 from the manuf. of $\text{Al}_2(\text{SO}_4)_3$ and alums by the action of H_2SO_4 on kaolin or ordinary clays.

Sodium stannate. HORACE R. McILKENNEY (to Vulcan Detinning Co.). U. S. 1,708,292, April 9. An aq. soln. of Na stannate and Na_2CO_3 such as that obtained by treating Sn -bearing material with NaOH is concd. by heating, in the course of which the soln. is continuously circulated until a substantial proportion of Na stannate crystallizes from the hot soln. while substantially all the Na_2CO_3 remains in soln.; the crystals of Na stannate are permitted to settle from the soln. upon a porous medium such as a filter screen and the residual hot soln. is sepd. from the layer of crystals. An app. is described.

Titanium oxide. JOSEPH BLUMENFELD (to Commercial Pigments Corp.). U. S. 1,707,248, April 2. Preliminary to Ti oxide manuf., FeSO_4 is removed from a soln. contg. Ti , ferrous Fe and H_2SO_4 by cooling the soln. to about 5° or lower and separating the FeSO_4 crystals which form.

Titanium dioxide. I. G. FARBERMAN. A. G. Brit. 296,720, Sept. 5, 1927. Hydrolysis of Ti -bearing solns. such as those obtained from the treatment of ores with H_2SO_4 , is effected in the presence of HF or a sol. fluoride. An easily filterable product is obtained which remains white even when ignited at 900° . In effecting the hydrolysis the soln. may be boiled and water may be added as the hydrolysis proceeds to reduce the action of free H_2SO_4 .

Titanium tetrachloride. CHARLES DE ROCHER (to Commercial Pigment Corp.). U. S. 1,707,257, April 2. Carbon (suitably in the form of coke or charcoal) is mixed with a titaniferous substance such as Ti ore and a colloidal suspension of TiCl_4 ; the mixt. is dried to form a tough mass, and fragments of the mass are subjected to the action of Cl_2 .

Preparation of hydrogen sulfide and its derivatives. SOC. STRUCKS REFINERIE DE LA HAZEL. Belg. 350,419, July 31, 1929. H and S are made to react in presence of a catalyst such as activated charcoal; e. g., H is passed through molten S and fresh H is added to the mixt. of H and S vapors to convert the excess of entrained S . The S remaining after the catalysis is removed by washing with $(\text{NH}_4)_2\text{S}$. An app. is described.

Storing alkali or other readily oxidizable metals in capillary tubes. D. H. BROPHY and W. A. RUTLAND (to British Thomson-Houston Co., Ltd.). Brit. 296,317, Aug. 29, 1927. A device is described in which, e. g., a mixt. of Ca and CaCl_2 may be heated to melt the metal which after deposition in the desired portion of the app. may be

with kerosene or paraffin and sealed in a capillary tube to which it is trans-

JOHN W. TURRENTINE. U. S. 1,708,287, April 9. In order to concentrate a com. scale, vapors of I such as those obtained by steam distn. from solns. contg. I counter-currentwise to a stream of liquid absorbent such as NaOH soln. **JULIEN BELLAY.** Fr. 647,478, Jan. 19, 1928. See Can. 282,952 (113). Pure H is obtained by producing water gas by the continuous treat-
e, lignite, peat, charcoal, etc., in an externally heated producer, enriching
by treatment with superheated steam in a heated column contg. fireclay
ad charcoal and purifying the resulting gas by passage through soda-lime
— tubes contg. masses of soda lime

hydrogen. **FRANZ GÖLKER.** Fr. 647,277, July 20, 1927. In the production of
the conversion of CO and H₂O in the presence of catalysts the reaction is carried
out in the presence of substances which will absorb CO₂, whereby the amt. of H₂O
may be reduced to that theoretically necessary. A mixt. of MgO and CaO may be
used. Cf. C. A. 22, 2247.

Catalytic production of hydrogen. **M. CASALE SACCHI.** Brit. 297,135, June 13,
1927. A mixt. of O (with or without N) and CO₂ is passed over carbonaceous fuel
heated to a high temp. and the CO thus formed is catalyzed with steam to produce H.
Catalyst poisons from the fuel are converted into an easily removable condition, e. g.,
S is converted into SO₂.

Mercury. **JAY G. DEREMER** to Savage DeRemer Corp., U. S. 1,707,471, April
2. In order to purify Hg for use in contact with EtCl in refrigerating app., it is mixed
with EtCl until the formation of solid matter as a result of the admixture ceases, and
the Hg and assocd. solid matter are then sep'd.

Phosphorus. **I. G. FARBENIND A. G.** Fr. 647,567, Jan. 21, 1928. Slags ob-
tained when crude phosphates are fused with C and aluminiferous material with distn.
of the P as such or as oxide are treated with HNO₃. The SiO₂ is filtered off. Al₂O₃
is pptd. by addn. of CaCO₃ or CaO, and Ca(NO₃)₂ is recovered from the filtrate by
evapn. Cf. C. A. 23, 1236.

Phosphorus and cement. **I. G. FARBENIND A. G.** Fr. 648,029, Jan. 31, 1928.
P or phosphoric acid and hydraulic cement in the latent state are produced simul-
taneously from crude phosphates, coke and material contg. SiO₂ and Al₂O₃, by heating
in an elec. or other furnace, the addns. being so made that the slag produced has a
compn. similar to that of blast-furnace slag (Al₂O₃ 12-35, SiO₂ 18-38, CaO 40-55%)
and being capable like it of conversion into blast furnace cement. Examples are given.
Cf. C. A. 23, 489.

Active carbon. **ERNST BERL.** Fr. 647,457, Jan. 18, 1928. See Brit. 283,968
(C. A. 22, 4212).

Carbon black. **ROY H. UHLINGER** to Thermatomic Carbon Co., U. S. 1,707,775,
April 2. See Can. 283,032 (C. A. 23, 940).

Gas carbon. **LOUIS GUMZ.** Ger. 472,345, June 26, 1927. In the manuf. of C by
the thermal decompn. of light hydrocarbons, a group of sep. cells having thin walls of
fireproof material is charged into an externally heated furnace. Hydrocarbon gases
are then led from above into each cell.

Sulfur. **KÄLMAN SZOMBATHY** and **ERICHARD VON AMMON.** Fr. 647,578, Jan. 21,
1928. Pure S, not contg. tar, is obtained from the mass used in gas purification, by
boiling the mass with excess of an alk. earth oxide or hydroxide and water, adding at
the same time or afterward an alkali carbonate or sulfate or both, filtering and treating
the filtrate with SO₂ or CO₂.

Pressure sulfur burner. **HENRY HOWARD** to Grasselli Chemical Co., U. S.
1,708,004, April 9. An app. is specified comprising a vertical, heat insulated, pressure-
resisting chamber with a vaporizing and burning section at its top, one or more com-
bustion sections below the vaporizing and burning section, and inlets for air and S
under superatm. pressure into the vaporizing and burning section, and an outlet for
withdrawing products of combustion at the bottom of the combustion chamber.

Sulfonated product for use in wetting, emulsifying, etc. **KARL MARX, KARL
BREDERSEN** and **KARL BITTNER** (to I. G. Farbenind A. G.) U. S. 1,708,103, April 9.
A mixt. of a brown coal-tar oil and solvent naphtha, tetrahydronaphthalene, PhCl or
other similar suitable compd. contg. an aromatic nucleus is treated with a sulfonating
agent such as chlorosulfonic acid.

Condensation products of indene with phenols. **I. G. FARBENIND A. G.** Brit.
297,075, June 14, 1927. Products suitable for use as intermediates, disinfectants and as
bases for lacquers are obtained by condensing indene and polyhydric phenols in the

presence of a halogen acid such as HCl. Indene and PhOH yield an oily product which after purification by distn. *in vacuo* is dissolved in a hydroaromatic hydrocarbon to produce crystals of hydrindylphenol; evapn. of solvent from the mother liquor leaves a viscous oily product insol. in alkali. The hydrindylphenol gives with bases, such as $(\text{CH}_2)_6\text{N}_4$, well-defined compds. Examples also are given of the condensation of a solvent naphtha fraction and crude cresol, indene and α -naphthol, α -xylylindene (prepd. by heating indene and xylyl chloride with KOH) and crude cresol or phenol, and indene fractions and *o*-cresol or resorcinol. Amino-, nitro- and chlorophenols, thymol or pyrocatechol also may be used.

Condensation products of urea or its derivatives and formaldehyde. I. G. FARBENIND. A.-G. Brit. 296,361, Feb. 28, 1927. The process described in Brit. 266,752 (C. A. 22, 849) is extended to the treatment of hydroxymethylurea, or hydroxymethyl compds. obtainable by condensing urea derivs. such as thiourea, *N*-methylurea and *N*-methylthiourea, with CH_2O , or the higher-mol. amorphous products resulting from such methylol compds. by splitting off water by the action of alk. condensing agents. Products are obtained which may be used for lacquers or other products. Phenols, colophony and protein-contg. materials such as casein and yeast may be added.

Condensation products of phenols and ketones. I. G. FARBENIND. A.-G. Fr. 647,464, Jan. 18, 1928. Phenols of the benzene series are condensed with cyclic hydroaromatic ketones by means of halogen acids, preferably in a soln. of AcOH. The products may be distd. in vacuum. Thus, cyclohexanone, phenol, AcOH and HCl are heated to 50° ; the product corresponds to 4,4'-dihydroxyphenylcyclohexane, which on distn. gives a new compd. probably 4-hydroxyphenylcyclohexane, m. 124° . In the same way cyclohexanone and *o*-cresol give 4,4'-dihydroxy-3,3'-dimethyldiphenyl-1,1'-cyclohexane, m. 186° , and *p*-methylcyclohexanone and phenol give 4,4'-dihydroxy-1,1'-diphenyl-4'-methylcyclohexane, m. 179° .

Purifying phenolic condensation products. BRITISH DYESTUFFS CORP., LTD., N. STRAFFORD and E. E. WALKER. Brit. 296,514, July 7, 1927. Free phenol and sol. condensation products such as those of low mol. wt. are removed from resinous phenolic condensation products by incorporating the resins with an inert filler such as wood meal or pulp, cotton or similar wastes, china clay or fuller's earth and extg. with a solvent such as water, C_6H_6 or ether. A similar extn. may be applied to fabrics impregnated with the material and after the extn. the sheets (such as paper or cloth) may be dried and pressed to form laminated products. The $p\text{H}$ is preferably adjusted to between 3.5 and 7.0 before the extn.

Plastic compositions. SINIT A.-G. Ger. 471,835, Aug. 19, 1924. Addn. to Ger. 455,551. In the prepn. of plastic masses according to the prior patent, aldehyde condensation products are used instead of C_2H_2 condensation products. Phenol-formaldehyde condensation products are given as an example.

Coloring plastic substances. GRIGORI PETROFF. Fr. 33,532, Feb. 18, 1927. Addn. to 629,251. Plastic condensation products of phenols with aldehydes to be colored with org. dyes are first treated with an aq. soln. of a phenol, sulfonic acid or sulfonated oil with or without an org. solvent. In some cases the phenol, etc., may be added with the dye.

Plastic compositions, lacquers, etc., containing cellulose esters or ethers. I. G. FARBENIND. A.-G. Brit. 296,796, April 9, 1927. Plasters, putties, "knifing" and filler compns. and lacquers comprise a cellulose ester or ether, a solvent and graphite or talc or both and may contain other fillers such as mica, asbestos, slag-wool, lithopone, white lead or ground slate (at least 3 times as much filler as cellulose deriv. being used). Plasticizing agents, resins, coloring substances, etc., also may be added, and various examples are given.

Molded articles. CHARLES E. TURRELL (to Monobloc Co.). U. S. 1,707,585, April 2. In forming hard molded articles such as storage-battery boxes, a suitable base such as a mixt. contg. gilsonite is mixed with cotton or other fibrous material and with vulcanizable rubber, S and cement while heating sufficiently to effect vulcanization of the rubber, and a definite quantity of the heated material thus prepd. is placed in a mold, molded and allowed to cool and harden.

Molding. ERICH WILL. Ger. 471,612, Aug. 11, 1925. A protective coating for a permanent mold is composed of a groundwork of kieselguhr in which borax or water-glass has been mixed.

Hydrogenation. LOUIS BOURDELLES. Fr. 647,075, May 20, 1927. Substances to be hydrogenated are acted upon in admixt. with H by ultra-violet or other short radiations.

Cleansing agents. JULIUS LAMPFERHOFF. Fr. 647,103, May 25, 1927. An

agent for dry cleaning walls, paint, etc., contains water 100g, flour 800, Zn stearate 100, CuSO_4 50, chrome alum 30 g.

Polishing liquid. PETER LANCHICK. Can. 288,382, April 2, 1929. A liquid polish suitable for automobiles comprises the expressed juice of orange fruit 1 part, alc. 2 parts, spirit of turpentine 3 parts, highly pulverized chalk 1 part, paraffin wax $\frac{1}{4}$ part dissolved in 1 part of coal oil, and viscous oil $\frac{1}{8}$ part.

Mixture for polishing varnished or other surfaces. ROBERT F. RAYNOR. U. S. 1,708,801, April 9. Benzine 4.75 oz. and paraffin oil 2.25 oz. are mixed with the product formed by pptg. a soln. of gum sandarac 15 grains in alc. 4.75 oz. by means of vinegar 4.75 oz. and sepg. the white ppt. which forms.

Composition for polishing silver, brass or other metals. G. RAWLINSON. Brit. 296,875, Aug. 11, 1927. Pptd. CaCO_3 4 lbs., NH_3 soln. 2 oz. and "Reckitt's blue powder" 0.5 oz. are used together.

Polishing cloth. JOHN C. KOUGH, JR. (one-half to Charles S. Chapman). U. S. 1,707,485, April 2. A compn. of mild abrading powders including whiting as a main ingredient and which also may include Sn oxide, rouge, etc., is incorporated by pressure in the interstices and fibers of a cotton fabric made of soft twisted loosely woven yarns, together with finely powdered rosin which serves as a retaining agent for the abrading powder. The cloth thus prepd. is suitable for polishing metals, varnished surfaces, etc.

Annular lime kiln. EDMUND JEENICKE. Ger. 471,920, April 12, 1927. A kiln for burning lime has compressed air admission pipes in the bottom of the burning chamber.

Regenerating kieselguhr after use for filtration. ALPHONSE M. DUPERU. U. S. 1,708,362, April 9. Moist kieselguhr such as that which has been used in filtering sugar solns. is mixed with finely divided dry kieselguhr to give it a "mealy" consistency and the mixt. is passed through a drying kiln, comminuted and subjected to burning while agitated with air; dust from the drying and burning kilns is collected in water and the water and assocd. dust is mixed with dry kieselguhr from a calcining kiln and the kieselguhr is freed from surplus water and washed. An app. is described.

Laminated mica products. TORAZO OKURI. U. S. 1,707,277, April 2. A binder for use with mica laminae in forming products such as elec. insulating plates is prepd. by heating under pressure an aq. mixt. including fire clay, an alkali metal borate, an alkali metal silicate, Mg chlorate and NaOH.

Compositions for indicating humidity. EMIL HUBER. Ger. 472,366, Aug. 3, 1927. Compns. of the kind comprising CoCl_2 , gelatin, and H_2O are improved by addn. of glycerol. A suitable compn. contains 2 kg. gelatin, 600 g. CoCl_2 and 120 cc. glycerol in 2 l. distd. H_2O .

Solution for use in separating different seeds. HARRY R. WARREN (to Warren-Teed Seed Co.). U. S. 1,708,435, April 9. A mixt. comprising NaNO_3 77, Na phosphate 3 and commercial glucose 20 parts is used for sepg. seeds by immersing the mixed seeds in the soln.

Dynamo brushes from powdered material. CHARLES F. SHERWOOD. U. S. 1,708,192, April 9. Powdered metals such as a mixt. of Cu, Pb, Sn and graphite are molded into the form of a brush with a portion of a preformed conductor molded into the brush, and the material is then sintered in a bath of molten Na salt such as NaCN having a m. p. between 650° and 815° and having a fluxing action on the metals being sintered.

Lead matrices for making printing surfaces. C. WINKLER. Brit. 297,289, March 15, 1928. Lead foil is pressed on to a form at a temp. of about 100 – 120° at which it is sufficiently plastic to receive a good impression in one operation. An ordinary steam or electrically heated stereotype matrix press may be used.

Printing on celluloid or similar materials. P. ALLMAN and H. N. MORRIS. Brit. 296,461, May 3, 1927. In printing on materials such as celluloid, rubber, phenol- CH_2O and casein- CH_2O condensation products, inks are used comprising a soln. of a coloring substance in a hydrogenated deriv. of phenol, naphthalene or naphthol or their isomers, esters or mixts. so selected that a soln. of the coloring substance is used, the solvent of which has a penetrating action on the material printed. The printing is preferably effected by the photogravure process.

Glazing. EMIL SPIDLER. Ger. 471,598, Nov. 22, 1927. Leather, wood and metal objects are glazed by squirting atomized material such as wax soln. or emulsion from a container carried by the brushing or polishing device.

Gear blanks formed of layers of fibrous cords impregnated with synthetic resin. WILLIAM H. ADAMS. U. S. 1,708,166, April 9. Structural features.

Stencil sheet. SHINJIRO HORII. U. S. reissue 17,267, April 9. See original pat. No. 1,587,954 (C. A. 20, 2567).

Foil transfer sheet. CARL H. VON HOESSLE and WALTER RICHTER (to Chemische Fabrik von Heyden). U. S. 1,707,828, April 2. A carrier film of smooth non-porous material such as cellulose, a cellulose ester or gelatin is used with a layer consisting mainly of waxes and a minor proportion of colophony, a middle layer of coloring material such as a bronze powder and a top layer of adhesive resinous materials encasing the particles of the middle layer. Sheets thus formed are suitable for ornamenting and printing purposes.

Artificial hair. JEAN BOYEUX. Fr. 647,178, June 3, 1927. Artificial hair is made by coating sized artificial silk with a soln. in alc. of gum lac or resin lac.

Dental amalgams. JOSEPH P. A. HUSNOT. Fr. 647,550, Jan. 21, 1928. Alloy^s are readily amalgamated with Hg in the presence of a few drops of dil. H₂SO₄ satd. with PhNO₂ and tinted red with erythrosin.

Composition for dental molds. LOUIS J. WEINSTEIN. U. S. 1,708,436, April 9. Plaster of Paris and silica are used with an admixture of H₃BO₃ (suitably about 2-5%).

Vermin-destroying composition. ANDREAS BURTSCHER. Ger. 472,498, July 22, 1926. See Swiss 127,471 (C. A. 23, 1231).

Fire-extinguishing composition. GUIDO BLENIO. U. S. 1,707,597, April 2. A compn. which generates a fire-extinguishing foam is formed by mixing Al oleate or other suitable Al soap with a carbonate.

Waterproof substance. DU PONT CELLOPHANE CO., INC. Fr. 647,330, Dec. 30, 1927. A substance which can be made into thin waterproof sheets is made by mixing a base, a gum, a wax and a plastifying agent and dissolving the mixt. in a solvent which will maintain the substances in complete soln. during drying. The soln. is dried at a temp. higher than the m. p. of the wax and preferably in a slightly moist atm. Examples contain (1) nitrocellulose 52, ester gum 35, dibutylphthalate 8.7, paraffin 4.3%, a solvent for which consists of alc. 25, ether 43, toluene 18 and AcOBu 14%; (2) nitrocellulose 50, gum Damar 34, tricresylphosphate 12, paraffin 4%, the solvent contg AcOEt 62, toluene 27, alc. 9 and AcOBu 2%.

19—GLASS, CLAY PRODUCTS, REFRACTORIES AND ENAMELED METALS

G. E. BARTON, C. H. KERR

The chemical surface treatment of glass. W. MINDT. *Glas- und App.* 9, 11 (1928); *J. Soc. Glass Tech.* 12, 236.—A general article dealing with etching media and the action of these, methods of use, advantages and disadvantages of the chem. treatment of glass, special etching processes such as ice and line etching and acid polishing.

H. L. D.

Chemical action in the annealing of glass. GUSTAVE KEPPELER. *Tech. Hochschule, Hannover. Sprechsaal* 61, 300-5(1928).—The two distinct actions in annealing glass are: (1) action in mass as a whole, (2) action on the surface. Data are presented based on these considerations which show the effect with no annealing compared with one and two annealings when the glasses are treated with different solns. R. A. H.

The behavior of glasses toward saturated water vapor. FRITZ FRIEDRICKS. *Sprechsaal* 61, 261-3, 282-5(1928).—The work of Förster and Hodkin, and Turner is reviewed. The 4 partial reactions occurring in connection with the conduct of glass toward satd. water vapor are (1) hydrolysis of the glasses, (2) the soln. of glass in water, (3) peptization of the silicic acid, (4) mineralization of the glasses. These 4 reactions are investigated by the autoclave method of Förster. The data obtained on 22 chem. glasses are given in tables and curves.

R. A. HEINDL

Studies on the production of glasses colored by sulfur. H. HEINRICHS AND C. A. BECKER. Kaiser Wilhelm Inst. *Sprechsaal* 61, 411-4(1928).—A discussion on the use of metallic sulfides, such as those of Cd, Al, Fe, Mg, Ni and Cu for the production of yellow tints and colors in glasses and the conditions under which these colors are best produced.

R. A. HEINDL

The durability of colors for painting on glass. F. GREINER. *Diamant* 50, 577, 598 (1928); *J. Soc. Glass Tech.* 12, 374-5.—A coloring matter for glass is a Pb silicate in combination with an inorg. color. An important factor in durability is the burning temp. This should be as high as is consistent with safety. The melting in of the flux materials may cause a diminution of the resistance of the glass. Blackening and

opacity of the blues have been eliminated. The durability of the glass is very much affected by the burning on of the colors. Reducing gases in the furnace result in the colors being badly fixed. New muffles absorb Pb and flux from the color. Muffles should always be burned out before use and a preliminary run with red lead given. For good burning, an oxidizing flame is necessary. Heated rooms have a bad effect by causing excessive perspiration which attacks the glass together with CO₂. A good protecting layer can be made by painting with a soln. of beeswax in turpentine.

H. I. D.

Physical examinations of glasses of considerable transparency to ultra-violet rays. A. RUTTENAUER. *Sprechsaal* 61, 449-50, 453-5(1928).—Although since 1907 there have been glasses which have transmitted ultra-violet rays, those glasses were rather unstable and were made only in the lab. The latest ultra-violet glasses are produced commercially and in most cases permit the passage of larger percentages of the waves under 300 μ than the old Schott and Company's Uviol glasses. The physiol. importance of the ultra-violet glasses lies in the fact that they may be used as window panes or as filters or casings when used in the building up of org. tissues and the prevention of diseases. Only the quantitatively detd. ultra-violet transmissibility of glasses permits their proper valuation. Detns. were made of the ultra-violet transmissibility of glasses used in therapeutic work. A simple test method is described. The transmission decreases with increasing temps. and also by intensive passage of the rays.

R. A. HEINDL

The manufacture of fused bifocal spectacle lenses. ROBERT J. MONTGOMERY. *J. Am. Ceram. Soc.* 12, 274-303(1929).—A crown glass, n 1.5230, is fused with a Pb glass, n 1.616 or 1.66 or 1.69. The problems involving thermal expansion, surface crystn., surface bubbles and the softening temps. of the glasses are difficult to control. The glass compns. are given. The so-called colorless bifocals are made by using a Ba glass in place of the Pb glass.

C. H. KERR

Method of determining free aluminum oxide in silicate mixtures and its application to the study of clays. L. A. SHMELEV. *Trans. Ceram. Research Inst.* (Moscow) 1928, No. 14, 24 pp.—A small quantity of the powd. silicate mixt. is treated in a test tube with a hot alc. soln. of alizarin red, the soln. having been previously satd. at the b. p. with boric acid to prevent coloration of the alkalies and alk.-earths. The contents of the test tube are boiled and decanted, and the residue is washed with a hot, satd. alc. soln. of boric acid. The extent to which the residue has become stained red indicates the amount of free Al₂O₃ present. Hydrargillite and diasporite do not react with the alizarin red soln., but they become strongly colored after heating for 2-5 mins. in the Bunsen flame. No liberation of Al₂O₃ from the kaolinite mol. was detected by this method between the temp. limits of 550° and 1100°.

B. C. A.

The compressive and transverse strength of brick. J. W. MCBURNEY. U. S. Bureau of Standards. *J. Am. Ceram. Soc.* 12, 217-29(1929); cf. C. A. 22, 1023.—Data are given on 27 makes.

C. H. KERR

Effect of typical slags on fire brick with a method of determination correlated to service. CHESTER E. GRIGSBY. *J. Am. Ceram. Soc.* 12, 241-63(1929).—In a rotary, slagging test furnace, tests were made on 50 fireclay and diasporite mixes, using high Fe₂O₃, high CaO and high Na₂O slags. Results are given in detail.

C. H. KERR

Masonry failures due to vertical shear. FRED T. HEATH. *J. Am. Ceram. Soc.* 12, 230-40(1929).

C. H. KERR

Concentration of hydrogen ions in ceramic materials. JOSEF ROBITSCHKE. *Chem. Ober* 4, 5-9(1929).—The properties of ceramic materials depend in no small degree on H-ion concn. of H₂O used for their manuf. The expts. performed with various clays showed that the max. strength of ceramic materials made from clays with high content of Al₂O₃ was obtained at $p_H = 7$. No effect of change of p_H , however, was observed with clays poor in Al₂O₃ and rich in SO₂. Cf. C. A. 20, 3547.

J. K.

Some properties of glaze slips. EDWARD SCHRAMM AND ROBERT F. SHERWOOD. *J. Am. Ceram. Soc.* 12, 270-3(1929).

C. H. KERR

Organic agents as aids to the adhesion and suspension of glazes. E. S. FOSTER. *J. Am. Ceram. Soc.* 12, 264-9(1929).

C. H. KERR

The failure of refractory materials at very high temperatures. M. W. TRAVERS. *Chemistry & Industry* 48, 106-7(1929).—The failure of refractory materials in most cases is a function of the viscosity of the interstitial glass. Freshly vitrified fireclay, e. g., shows in microscopic section little but homogeneous, opaque or glassy material with a few needle crystals of mullite. On further heating, especially if in contact with mineralizers, microscopic examn. shows the fireclay material to consist of increased numbers of mullite crystals in a glassy matrix of low viscosity. Failure of the refractory

may now occur especially under load. *Sillimanite* on heating forms mullite crystals and a highly viscous matrix of SiO_2 , which accounts for the excellence of sillimanite refractories.

L. B. MILLER

Deformation of refractory material under load at high temperatures. E. KÖHLER. *Trans. Ceramic Research Inst. (Moscow)* 1928, No. 12, 119 pp.—The various methods of detg. refractoriness-under-load are reviewed, and preference is given to the method which measures the degree of deformation under a given load under the influence of a gradually rising temp. Tests were carried out with app. consisting essentially of an elec. C-resistance furnace provided with a system of levers for applying the load. A pointer recorded the movements of the test piece, magnified 10 times, on a suitable scale. A constant load of 1 kg./sq. cm. was applied, and the temp. rose at the rate of 300° per hr. up to 950°, and thereafter at 240° per hr. Temps. were measured with a thermo-element, protected by a special tube passing through the bottom of the furnace, the junction of the element being level with, and in close proximity to, the lower third of the test piece. The test pieces were cylinders 50 mm. high and 35.7 mm. in diam. The results of tests made on Russian clays showed that the finer the grog, the higher was the temp. of initial softening; a 40% deformation, however, occurred at a lower temp. with the fine grog mixts. than with the coarser grog mixts. Bodies contg. mixed grog sizes showed greater resistance to deformation than bodies with one fraction, whether fine or coarse. With mixts. made from one clay, a close relationship was noted between the max. strength (cold), the temp. at which a 4% deformation took place under load, and the firing shrinkage corresponding to the max. cold strength. A low-fired grog produced better cohesion between the grog grains and the bonding clay. The ratio of grog to bond, within the limits of 35 to 55% of bond, had no effect on the strength under load. Kaolin-grog bodies were also prepd. and fired to different temps. Best results in the under-load test were obtained with bricks fired at cone 28.

B. C. A.

The chemical analysis of silicates (ROBITSCHER) 7. Evolution in conceptions of continuous furnaces and methods of heating them (HIRT) 1. The cause of thermo-tribo-electric abnormality of glass (MONTE) 2. Muffle furnace for vitreous enameling (Brit. pat. 296,936) 1. Colored bituminous compositions for making tiles, blocks, etc (Brit. pat. 296,626) 22. Extraction of clay [from crude or waste coal, iron ores, etc] (Fr. pat. 647,928) 13.

MILLER, G. B.: **Etching of Glass** (in German). Berlin: A. Hartleben. \$1 25
Reviewed in *Ceram. Ind.* 12, 226(1929); *Ceram. Abstracts* 8, 245(1929).

Glass transparent to ultra-violet rays. SOC. ANON. DES MANUF. DES GLACES ET PRODUITS CHIM. DE SAINT-GOBAIN, CHAUNY ET CIREY. Fr. 647,188, June 4, 1927. See Brit. 291,468 (C. A. 23, 1235).

Glass making. NAAMLÖÖZE VENNOOTSCHAP MIJ TOT BEHEER EN EXPLOIT. VAN OCTROOIEN. Fr. 647,650, Jan. 24, 1928. Guides for sheet glass between the rollers, etc., are described. Cf. C. A. 23, 2262.

Apparatus for gathering glass by suction, etc. S. HUNT. Brit. 297,142-3, June 15, 1927. Structural features.

Apparatus for supplying molten glass. DEUTSCHER VERBAND DER FLASCHENFABRIKEN G. M. B. H. Ger. 472,140, Aug. 24, 1924.

Apparatus for temperature regulation and delivery of viscous glass from furnaces. OLIVER M. TUCKER and WILLIAM A. REEVES (to Hartford-Empire Co.). U. S. 1,708,037, April 9. U. S. 1,708,069 also relates to similar app.

Apparatus for cooling sheet glass. JESSE W. WILDERMUTH (to Libbey-Owens Sheet Glass Co.). U. S. 1,707,242, April 2.

Producing designs on sheet glass. EDWARD DANNER. Ger. 472,314, June 21, 1925. A stream of glass is guided on to an impression roller provided with designs and while plastic is forced into contact therewith by gas pressure.

Rolling and annealing glass sheets. SOC. ANON. DES MANUFACTURES DES GLACES ET PRODUITS CHIMIQUES DE ST.-GOBAIN, CHAUNY ET CIREY. Brit. 296,282, Feb. 18, 1928. Mech. features.

Annealing sheet glass in tunnel leers. EMPIRE MACHINE CO. Ger. 472,142, Mar. 11, 1924. Gases are supplied to the tunnel above and below the glass level and the of the streams are adjusted so as to obtain uniform cooling on both faces of the

Leer for annealing glassware. VERGIL MULHOLLAND (to Hartford-Empire Co.). U. S. reissue 17,263, April 9. See original pat. No. 1,571,137 (C. A. 20, 976).

Surfaces for working plastic glass. SENDLINGER OPTISCHE GLASWERKE G. M. B. H. Ger. 472,141, July 10, 1925. Surfaces such as chamotte plates on which glass is to be worked while soft are coated with H_2WO_4 or H_2SnO_3 , or compds. thereof such as $CaWO_4$, to prevent adhesion of the glass.

Hollow bodies from quartz glass. FRITZ ECKERT. Ger. 472,143, April 22, 1927. In making hollow bodies from quartz glass by melting powd. quartz on to a quartz glass hollow body, a cooling agent is led through the hollow body during the melting.

Reinforced glass. P. J. PORT and J. NEWTON. Brit. 296,825, June 13, 1927. One face of each of 2 sheets of glass is coated with a soln. of albumin in distd. water, the coatings are dried and there is then applied to them a soln. of pyroxylin in ether or absolute alc. or $AmOAc$ which is also dried. The 2 sheets are then united under pressure, at a temp. of 40–50°, with a celluloid sheet which has been immersed in an alc. soln. of dimethylamine to which a small proportion of $HOAc$ also may have been added. The edges of the compound sheet may be sealed by collodion or celluloid.

Making wire glass. HENRY F. CLARK (to Window Glass Machine Co.). U. S. 1,708,662, April 9. Mech. features.

Bricks, tiles, etc. ÉMILE FRANKEN. Fr. 647,350, Jan. 7, 1928. Sawdust or wood shavings is agglomerated with Na_2SiO_3 and made into bricks, tiles, etc.

Burning argillaceous material to reduce light-weight aggregate for concrete sewer pipe, brick, etc. STEPHEN J. HAYDE (to American Aggregate Co.) U. S. 1,707,395, April 2. The material is subjected to the highest temp. used in burning, at the beginning of the burning process, in order to produce a vesicular material and the product is crushed.

Apparatus for sifting potters' slip, etc. J. W. RATCLIFFE and E. COTTON, LTD. Brit. 296,959, April 5, 1928. Structural features.

Continuous furnace for ceramic ware. JOSEPH A. DEDOUCH. U. S. 1,708,083, April 9. Structural features.

Continuous furnace for ceramic products. JOSEPH A. DEDOUCH. U. S. 1,708,124, April 9. Structural features.

Kiln for burning terra cotta, sanitary ware, etc. CARBORUNDUM CO., LTD. Brit. 297,241, Nov. 12, 1927. Structural features.

Apparatus for feeding plastic ceramic material to molds. WM. J. MILLER. Fr. 647,763, Jan. 17, 1928.

Casting porcelain articles such as artificial teeth. KUNSTZAHN GES. Brit. 296,765, Sept. 7, 1927. A raw material for use in casting teeth or fillings consists of porcelain grains of substantially spherical form produced by casting a viscous porcelain mass onto a chemically inert base, breaking the casting into small pieces after it has cooled, and subsequently rendering the pieces sufficiently fluid that they assume the desired form.

Glaze. KARL STOLL. Fr. 647,834, Dec. 29, 1927. See Brit. 282,786 (C. A. 22, 3971).

Refractory materials. UNITED STATES METALS REFINING CO. Fr. 33,578, May 6, 1927. Addn. to 607,611. In the manuf. of molded refractory materials the magnesite used is powdered to different degrees of fineness, before its mixt. with siccative oil so that during mixing and molding the fine particles penetrate between the larger and give a denser product.

Diaphragm for surface combustion apparatus. FREDERICK J. COX. U. S. 1,707,976, April 9. A molded porous diaphragm is formed of refractory material, partly in granular and partly in powdered form, together with a binding material, e. g., of fire clay and Na silicate.

Abrasives. H. R. POWER (to Carborundum Co., Ltd.). Brit. 296,195, Aug. 30, 1927. See U. S. 1,661,849 (C. A. 22, 1452).

Enamel having a cement base. J. PEETERS. Belg. 352,464, July 31, 1928. The enamel is formed of a mixt. of cement, $CaCO_3$ and coloring oxides rendered liquid by addn. of an aq. rosin emulsion. After being coated with this enamel, the objects are heated in a closed vessel.

White enamel for incandescent lamps. FRANZ SKAUPY, HEINZ NACHOD and GEORG GAIDIES (to General Electric Co.). U. S. 1,708,743, April 9. A white enamel is formed of Pb oxide 65, ZnO 15, B_2O_3 20 and "arsenic" 0.5 part.

20—CEMENT AND OTHER BUILDING MATERIALS

J. C. WITT

Waste-heat equipment for portland-cement mills. L. ECK. *Pit and Quarry* 17, No. 7, 59-63(1929).—A description of the installation of waste-heat equipment back of the rotary kilns. Full details of the installation in a Halle cement mill are given.

J. W. SHIPLEY

Some observations concerning the health of cement workers. A. J. R. CURTIS. *Rock Products* 31, No. 20, 75-7(1928); *Public Health Eng. Absts.* E-785b, 1.—This paper deals with a study of the health of the workers in a portland cement plant. The case histories of the 21 cases suspected or positive for tuberculosis are quoted and the chief finding, that portland cement does not incite the development of pulmonary tuberculosis, is discussed. C. points out that while this study disclosed a high rate of upper respiratory disease affection, there is ground for belief that exposure to the weather and low standards of living have a great deal to do with this high rate of minor respiratory disease. As proof of this he cites the experience of various mill executives to the effect that no higher rate of absenteeism exists in dusty mills than in non-dusty ones. The existence of other ailments such as skin diseases is mentioned and the importance of personal hygiene emphasized. Conjunctivitis is also stressed with reference to personal hygiene.

Impregnation of wood by electroösmosis. B. F. SCHWARZ. *Inst. du Pin. Bull. inst. pin* No. 57, 88-90(Feb., 1929). See *C. A.* 23, 948.

A. PAPINEAU-COUTURE

The treatment of mine timber. W. ENGELS. *Glückauf* 64, 1473-82(1928).—Pressure impregnation is preferable to dipping as it causes deeper penetration not only during treatment but also during use. The best preservatives both from the point of view of protection against fungi and economy are dil. solns. (1 or 2%) of Basilit (89% NaF and 11% dinitrophenylaniline) and Triolith (85% NaF, 10% dinitrophenol and 5% $\text{Na}_2\text{Cr}_2\text{O}_7$). Their use increases the life of the timber to 20 yrs. Chem. combination between dinitrophenol and the outer portion of the wood may account for protection from the outside, while diffusion of NaF into the interior destroys the possibilities of decay there. Glückauf Basilit (85% Triolith and 15% NaCl), although it renders timber less in flammable, is not as effective because of the leaching out of NaCl. While HgCl_2 solns. can be applied only by the dipping process they increase the life of timber to 10 yrs. provided no Fe (which destroys the preservative) is used in construction. The use of NaCl solns. doubles the life of timbers, the fungus resisting properties depending not on any toxic action of NaCl but on its removing from the fungus the H_2O necessary for life. The coating processes "Torkret" and "Velo" are also of minor value; The cement used acts like a valve, preventing decay only in an atm. contg. less than 85-95% moisture. The fungicidal action of tar oil may be attributed to the volatile tar-acid portion, the concn. of which decreases in time. The strength of the timber is inversely proportional to the salt content. Tar oil causes a 10% increase in strength but destroys the wearing properties of wood in consequence of the transformation of the cell walls into a horn-like substance. Comparison of the effect of various preservatives should be made with timbers having similar structure and thickness as well as similar moisture content. Before treated timber is installed economic factors must be considered such as the rock pressure, lifetime of the workings, and that of the raw wood. Timber should be treated only when calcs. show that the life of the timber will be at least doubled thereby.

J. B. SHOHAN

Reaction of water on Ca aluminates (WELLS) 6. **Rubber roadways (CHAPMAN) 30.** **Chemistry of road tar (MALLISON) 22.** **Trinidad asphalt in road building (ANON) 22.** **The limestone resources of the Pontiac-Fairbury region (LAMAR) 18.** **Colored bituminous compositions for road surfaces, etc. (Brit. pat. 206,626) 22.** **Glaze (Fr. pat. 647,834) 19.** **Cement (Fr. pat. 648,029) 18.**

Cement. INTERNATIONAL PRECIPITATION CO. Fr. 647,250, Aug. 24, 1927. Portland cement is mixed with a plastifying and impermeablizing agent contg. a natural mixt. of earthy material such as a clay schist or diatomaceous earth and an oily or bituminous substance. The proportion is preferably 1 of plastifying agent to 10-20 of cement.

Feeding cement slurry to rotary kilns. NIELS NIELSON (to F. L. Smidth & Co.). U. S. 1,708,705, April 9. Slurry is introduced into the kiln as a fine spray and dust passing out of the feed end of the kiln is collected and delivered into the path of the

slurry spray so that the latter carries the escaping dust back into the kiln. Various structural features are described.

Rotary kiln suitable for burning cement. JOHAN S. FASTING (to F. L. Smidth & Co.). U. S. 1,708,693, April 9. Structural features.

Waste-heat-boiler plant for operation with cement kilns. FRANK G. McKELVY and JOHN E. BELL. U. S. 1,707,964, April 2. Various structural features are specified.

Fibers for cement. SOC. GÉNÉRALE D'EXPLOITATIONS INDUSTRIELLES. Fr. 647,089, May 23, 1927. Mineral fibers such as asbestos to be used in cement making are treated with dil. H_2SO_4 to facilitate opening up. Fibers which are not attacked by dil. acid are treated with alk. silicate and subsequently with an acid.

Siliceous stones. CONTOR FEUERFESTER MATERIALIEN G. M. B. H. Fr. 647,702, Jan. 26, 1928. Finely basic cements are used as agglutinants in the manuf. of siliceous stones by calcination of quartzites, siliceous and cryst. quartz, etc., of medium quality at a temp. above 1500° .

Artificial stone. GEORGES BIA and J. É. DOUZAL DE GRANVILLE DE BIELIZE. Fr. 647,083, May 21, 1927. Artificial stone is formed of chlorosulfates of Mg and Zn by mixing $MgSO_4$ and $ZnSO_4$ with MgO and $MgCl_2$. Stone dust, waste sand, etc., may be added.

Pavement construction. LEON R. MACKENZIE. U. S. 1,707,939, April 2. A course of asphaltic material is laid which contains aggregate having a dimension greater than half the thickness of the course and expanded steel or other material in the central portion of the layer serves to permit vertical movement of the rock aggregate under compression (by traffic or otherwise) without permitting any substantial horizontal movement.

Repairing cuts in pavements with wet self-hardening paving material. LE VERN FOX. U. S. 1,707,391, April 2. Mech. features.

Residues from lubricating oils for use on roads. WILHELM H. SCHMITZ. Fr. 647,897, Jan. 21, 1928. Residues from the purification of lubricating oils are emulsified in water with asphalt and used on roads.

Forming thick sheets of asbestos-concrete or like material. JOHN C. MACILLOWIE (to Asbestos Wood and Shingle Co.). U. S. 1,708,842, April 9. Mech. features.

Composition of fiber and thermoplastic rubber derivative. HARLAN L. TRUMBULL (to B. F. Goodrich Co.). U. S. 1,708,111, April 9. A compn. suitable for use in sheet or board form comprises sulfite pulp, straw, cotton or other fibrous material, the individual fibers of which are sepd. from each other and surrounded with a thermoplastic rubber deriv. such as that produced by the action of *p*-toluenesulfonic acid and H_2SO_4 on rubber.

Building felt. RAY P. PERRY (to The Barrett Co.). U. S. 1,707,491, April 2. An aq. mixt. of paper-making stock and an emulsion contg. waterproofing material such as asphalt and stearite is formed into sheets on a paper-making app.

Building boards from waste wood products. ARTHUR E. MILLINGTON. U. S. 1,708,586, April 9. Waste wood material such as slabs or bark is disintegrated, softened by treatment with a soln. of salt and Na_2CO_3 and water and steam under pressure, refined and formed into boards.

Agglomerating wood charcoal. ÉMILE A. BARBET. Fr. 647,173, June 3, 1927. Wood charcoal is agglomerated with sugar molasses which has been treated with viscous ferments such as "sugar gum" or "frog spawn," whereby the agglomerating properties are greatly increased.

Artificial wood. GEORGES BIA and JEAN É. DOUZAL DE GRANVILLE DE BIELIZE. Fr. 647,082, May 21, 1927. Artificial wood is made by mixing sawdust and asbestos with linseed oil and the condensation products of $PhOH$ and CH_2O , MgO , $MgSO_4$ or $ZnSO_4$ may be added.

Preserving wood. W. IWANOWSKI and J. TURSKI. Brit. 296,332, April 28, 1927. See Fr. 634,106 (C. A. 22, 3756).

Permeating wood with metallic substances. KAISER-WILHELM-INSTITUT FÜR EISENFORSCHUNG. Brit. 296,986, Sept. 10, 1927. Wood or similar fibrous material is impregnated with liquid metals or liquid alloys for producing an elec. cond. material, or for preserving the wood or obtaining a product retaining the fibrous grain and which can be polished like metal.

The cold impregnation of wood to protect it from parasites such as termites, etc. C. DE ZUTTERE. Belg. 351,173, June 30, 1928. The product consists of primary tar obtained by the carbonization of coal and certain lignites at a temp. below 560° , of oil obtained by fractionation of the said tar and contg. 47-60% phenols, of a light benzene oil and of crude commercial $PhNH_2$. Cf. C. A. 23, 2010.

The spontaneous combustion of semi-coke from brown coal: Its causes and prevention. P. ROSIN. *Fuel in Science & Practice* 8, 66-78(1929); *Braunkohle* 27, 241-56, 282-92(1928); cf. *C. A.* 22, 2453.

D. A. REYNOLDS

The maximal carbon dioxide content. R. NITZSCHMANN. *Metallbörse* 18, 1968 (1928).—For every fuel, solid, liquid, or gaseous, let A = combustible C, a = C present as CO_2 , B = free H_2 , C = free O_2 , D = gaseous N_2 , all in weight %, n = vol. % O_2 , $100 - n$ = vol. % N_2 of the air for combustion and k_{\max} = highest possible vol. % CO_2 in the water-free combustion gases; then $k_{\max} = 100n(A + a)/[100A + (100 - n)(3B - 0.375C) + n(a + 0.428D)]$. For pure O_2 , $n = 100$ and $k_{\max} = (A + a)/(A + a + 0.428D)$. When $n = 20.9$, i. e., for air, $k_{\max} = 100(A + a)/(4.784A + 11.354B - 1.4192C + a + 0.428D)$. Thus for the liquid fuels C_nH_m , as $A = [(12n/12n + m)]100$ and $B = [(m/12(n + m))]100$, k_{\max} can be calcd., e. g., for benzene, naphthalene, pentane, hexane, heptane, $k_{\max} = 17.5, 18.04, 14.17, 14.29, 14.39$ (all %), respectively, while in pure O_2 , all obviously give $k_{\max} = 100$. In gaseous fuel let $V_1, V_2, V_3, V_4, V_5, V_6$ be the respective vol. % of $\text{CO}_2, \text{CO}, \text{CH}_4, \text{O}_2, \text{H}_2, \text{N}_2$; then $A = 0.00536(V_2 + V_3)$, $a = 0.00536 V_1$, $B = 0.000893(2V_3 + V_4)$, $C = 0.00715(V_2 + 2V_4)$, $D = 0.0125 V_6$. $k_{\max} = 200(V_1 + V_2 + V_3)/[2V_1 + V_2 - 2V_3 + 2V_4 - V_5 + 2V_6 + (100/n)(V_2 + 4V_3 - 2V_4 + V_5)]$; whence for pure O_2 , $n = 100$, $k_{\max} = 100(V_1 + V_2 + V_3)/(V_1 + V_2 + V_3 + V_5)$ and for air, $\text{O}_2 = 20.9$, $k_{\max} = 100(V_1 + V_2 + V_3)/(V_1 + 2.892 V_2 + 8.568 V_3 - 3.784 V_4 + 1.892 V_5 + V_6)$.

S. L. B. E.

Fuel consumption of large furnaces. M. LAFFARGUE. *Chaleur ind.* 9, 379-83(1928).—Some furnaces require 700,000 cal. per ton of iron charged (cold); better furnaces require 350,000 cal. and these improved results have been obtained with very poor fuel. Actually, heating the iron to 1250° requires about 200,000 cal. per ton. The losses are (a) heat radiated by the furnace, which can be measured and (b) heat taken off by the gases, which can also be detd. L. found a large loss of radiant heat from the top of the reheating furnace. Heat loss through the chimney varies with the amt. of inert matter in the fuel, amt. of excess air, and with the temp. of the gases. The flues act as recuperators of the heat losses from the chamber. The heating chamber may be treated as a const. source of heat and the temp. of the flame in the chamber should be const. The temp. of the furnace will depend upon the theoretical temp. of the flame, concn. of the flame, heat capacity of the walls, etc., and surface of iron to be reheated. Each of these factors is dealt with in turn. A discussion is given.

S. L. B. ETHERTON

Steam generation at high pressures and temperatures. I. Preliminary study. ST. LOEFFLER. *Tech. Hochschule, Charlottenburg. Power* 69, 486-9(1929). A discussion of standard boilers used in high-pressure steam generation. II. The Loeffler boiler. *Ibid* 524-7.—A detailed and illustrated description. "The heating medium is steam which, taken from the vaporizer and forced to circulate by the pump, is superheated in a coil set in a furnace, and then blown into the water contained in the vaporizer. A portion of the superheated steam is led away to be used by the engine."

D. B. DILL

A résumé of high steam pressures in the industrial plant. P. W. SWAIN. *Power* 69, 582-5(1929).—The possibilities of by-product power justify a wide pressure range in industrial plants. A chart shows the expansion of steam in a series of 10 stages, from 0 to 1450 lbs. per sq. in. The adiabatic heat drops in each stage are taken such that with a stage efficiency of 70% the stage will produce 1 kw. hr. from each 100 lbs. of steam passing through the turbine.

D. B. DILL

Coal. F. C. WIRZ. *Intern. Congress Testing Materials* 1927, II, 659-63. Emphasis is given to the importance to buyers, miners and dealers of a knowledge of

the compn. and characteristics of a given fuel as making it suitable for specific uses: power plant, metallurgical, gas manuf. and coke production. The relative values of different tests and methods used to det. the compn. and properties of coal and coke are discussed.

of the results of their investigations, but no references are given to the journals in which the articles were published. A no. of the tests developed for detg. the swelling, coking and reactivity properties of coal and coke are outlined and compared from the practical standpoint.

W. W. HODGE

A new method of studying the microstructure of coal: Etching by tetralin. CHOZO IWASAKI. *Fuel in Science & Practice* 8, 143-4(1929).—Tetralin at 190 to 200° generally dissolves well the newly formed humic substance in coal. Very young coals and highly coalified ones are dissolved only with difficulty; hence this solvent, as an etching agent, is suitable to black lignites and low-rank bituminous coals. When less coalified plant remains are embedded in a comparatively well coalified ground-mass, the former stands in relief while the latter is etched by the reagent. Thus either anthraxylon or attritus may be the more greatly attacked by tetralin, depending upon the relative degree of coalification of these constituents.

D. A. REYNOLDS

The significance of the inorganic constituents of coal in fuel technology. K. BAUM. *Glückauf* 64, 1733-41(1928).—B. reviews the literature on coal ash—its economic importance, compn. and effect on coking and combustion processes. He further reviews the older methods of fusion-point detn. and describes the recent method of Bunte and Baum (C. A. 22, 145). The work of Prost, Teume, Haslam and others on the system $\text{SiO}_2\text{-Al}_2\text{O}_3$ -bases is discussed, and an explanation offered for the mechanism of slag formation. This is governed essentially by three factors (1) the melting or soln. process which is explained by the fusion curves, (2) the atm. (oxidizing or reducing) in the fuel bed, (3) the nature of the fuel in which the ash is distributed. J. B. S.

A rapid method for the determination of nitrogen in coal. J. W. WHITAKER. *Fuel in Science & Practice* 8, 145(1929).—The coal is rapidly oxidized with strong H_2SO_4 and KMnO_4 and the NH_3 estd. by nesslerizing. Specific details of the method are given. The results by this method check well with those obtained by the method of Kjeldahl, Wilfarth and Gunning.

D. A. REYNOLDS

Use of pulverized coal in marine engines. B. D. MOORE. *Iron & Steel Can.* 11, 368-71(1928).—Tests made by the U. S. Shipping Board on the 9730-ton cargo ship *Mercer*, on four round trips between New York and Rotterdam, using pulverized coal in Scotch marine boilers, were highly successful. Pulverized coal (75% through a 300 mesh) and high-flame turbulence combined with equal distribution of coal to the furnaces were found necessary for the best results. Storage of pulverized coal over inert CO_2 at the quay-side is suggested as practicable. Ships with double bottoms on long voyages would find oil fuel more economical but where bunkering does not affect the cargo-carrying capacity pulverized-coal-burning ships would have an advantage over oil-fired ships or motor boats.

J. W. SHIPLEY

Trenton Channel Station eliminates powdered coal dust from cyclone vents. H. E. MACOMBER. *Detroit Edison Co. Power* 69, 464-7(1929).—Bag-filter equipment efficiently recovers coal dust. Hoppers and ducts are heat insulated and preheated air is added to the vent mixt. to prevent condensation.

D. B. DILL

Lignite gives 71 per cent efficiency. G. W. WELSH. Otter Tail Power Co., Washburn, N. D. *Power* 69, 385-7(1929).—The lignite used has 6000 to 6500 B. t. u. per lb., 40% H_2O , 6 to 8% ash, 28% fixed C and 27% volatile. Details of operation are described.

D. B. DILL

The influence of inorganic materials in lignite carbonization. A. W. GAUGER AND D. J. SALLEY. *Fuel in Science & Practice* 8, 79-85(1929).—The effect was studied of the addn. of various inorg. reagents to lignite from the Truax-Traer mine at Velva, N. Dakota, upon its carbonization. The lignite was air dried and ground to pass a 20-mesh sieve, then ground together with 5% of reagent (in aq. soln.) in a mortar. Briquets were made of the mixts. thus prepd. and these were carbonized in a Fischer Al retort at 500° for 1.5 hrs. Tests were made at 850°, a similar retort made of Cu being used. The yields of char, tar and gas were measured and the character of the chars was studied. Conclusions: (1) Inorg. materials may exert a specific effect on

the structure of the char as well as on the yield of char, tar and gas. (2) Hydrates of AlCl_3 , $\text{Al}_2(\text{SO}_4)_3$, $\text{Al}(\text{NO}_3)_3$, MgSO_4 , MgCl_2 and SrCl_2 alter the structure of the char produced, yielding a hard pseudo-coke differing materially from the soft, powd. char of the untreated coal, whereas the anhyd. salts produce soft, fine chars. (3) FeCl_3 hydrate increases the yield of char at the expense of the tar. (4) Na_2CO_3 decreases char and tar yields and increases gas yields. (5) SiO_2 is without effect. D. A. R.

Low-temperature carbonization developed commercially. G. L. MONTGOMERY. *Power* 69, 593-5(1929).—The plant nearing completion at New Brunswick, N. J., has a capacity of 250,000 tons per yr. Each ton yields 1200 lbs. salable smokeless fuel, 300 lbs. fines used to make producer gas, 3500 cu. ft. of 900 B. t. u. gas, 25 gals. of tar, and about 2.5 gals. of light oil (a satisfactory anti-knock motor fuel). The set-up and operation of the plant are described. D. B. DILL

Recovery of primal substances through the distillation of coal. CONSTANTIN, REDZICH. *Apparatebau* 41, 49-52(1929).—Description, with 4 cuts, of plants for the production of motor fuels, benzene, oils, paraffin, creosotes, asphalt, tar, etc.

J. H. MOORE

The work of the Emscher association on the recovery of phenol from ammonia liquors of the Ruhr mining companies. H. WIEGMANN. *Glückauf* 64, 397-404, 435-451(1928).— NH_3 liquor is washed with benzene, toluene or other suitable extn. liquid, the wash medium is sepd., and the solvent is recovered and reused. The phenol-contg. benzene may also be washed with soda lye and the alkali regenerated and reused after caustification. Accounts are given of the installations at Dorsfeld, Mathias Stinnes, and König Ludwig and Jacobi mining companies and of the Emscher association, together with 5 flow sheets. The plants comprise, in general, a raw-liquor vessel, filter, clear-water container, heat exchanger, mixing pump, sepg. vessel, distn. app., benzene reservoir, phenol reservoir and coolers. As a rule, a plant will treat 120-150 cu. m./day of liquor contg. about 3-4.5 g. phenol/l. Cost figures for the installations are analyzed. Phenol removal from the waters is improved by warming, by better contact with benzene, by having purer ammonia water and washing by counter current. The operation, the layout, efficiencies and results are discussed in detail for every installation. In each company the ammonia water and washing benzene were different but it is of the utmost importance to use a benzene suitable to the wash water. At one place a light benzene, b. 77.5° , 44% at 80° , 96% at 85° , was best; at another place normal benzene (90%) was used; and at a third place the benzene used was almost a toluene, i. e., 15% at 100° , 74% at 110° , 90% at 114.5° , 95% at 118° . Benzene contg. pyridine exts. the phenol better than pure benzene. The direct and indirect recovery of wash fluid is discussed. The purest crude phenol oil obtained by benzene washing of NH_3 liquor contains PhOH 85, C_6H_6 6, $\text{C}_6\text{H}_5\text{N}$ 4 and tar 5%. At another plant was obtained a phenol oil of the compn phenol 75, C_6H_6 15, $\text{C}_6\text{H}_5\text{N}$ 4 and tar 6%. The crude phenol oil was readily salable. Since the chief item of expense in the recovery is steam, alkali washing of the benzene ext. was tried. Alkali washing involves a plant for recovery of pyridine bases. Such a combination has given good results in the U. S., but German practice has not yet gone so far. A phenol balance and concn. of phenol in gas liquor are discussed. The waste liquor after phenol extn. contains 0.7-0.8 g./l. About 25% benzene, on the waters, is required, and about 1.2-1.4 g./l. remains in the water and must be recovered. The utilization of the process in the Emscher district has given 5000 tons of phenol, 75% crude phenol now brings 75-8¢/kg., the material being easily marketed. S. L. B. E.

The economic position of dephenolating plants. A. WEINDEL. *Glückauf* 64, 498-502(1928).—The water soly. of phenol homologs falls with increasing mol. wt., hence extn. with an org. solvent will preferentially remove the cresols and xylenols while the more sol. phenol will tend to remain and be lost, thereby defeating water pollution regulations and also diminishing revenue. In attempting to improve phenol recovery, a distn. process of removing the benzene is ruled out because of excessive steam charges. A better recovery can be obtained with alkali treatment. All that is required is to treat the liquors with alkali more often and to regenerate the alkali in between. The cost of additional pumping, etc., is negligible compared with added steam costs. Such improvements will enable plants whose liquors contain but 2 g./l. phenol also to come within the scheme of recovery. W. considers there is more pyridine in the ammonia liquors than in the crude light oils, about 0.3 g./l. of crude liquor and pyridine recovery would be an advantage. A serious difficulty in the phenolate process is deposition troubles. W. discusses in detail two suggestions for carrying out the phenolate process and gives estns. and calcns. connected with yield, costs and revenue that correspond. S. L. B. ETHERTON

The phenol solubility of humic acids. M. SOUM AND F. PODBREZNIK. *Inst. du Pin. Bull. inst. pin.* No. 57, 61-4 (Feb., 1929).—It is shown that humic acids, which up till now had been considered sol. only in C_6H_5N and in alkalis, can also be dissolved by $PhOH$, which shows their similarity with lignin and would seem to confirm the hypothesis of Fischer and Schrader according to which humic compds. in fossil fuels are formed from lignin. $PhOH$ not only dissolves free humic acid, but also renders the more highly condensed humic compds. sol. by a depolymerization which is very probably similar to that obtained by fusion with alkali. It is suggested that humic compds. could be detd. in fuels by extn. with $PhOH$, as lignin can be in wood. A. P.-C.

Study of the possibility of using wood carbonized at low temperature as a fuel in gas producers (for motor vehicles). G. DUPONT, LUSSAUD AND ALLARD. *Inst. du Pin. Bull. inst. pin.* No. 57, 64-5 (1929).—The advantages of charcoal for the above purpose are uniform compn., fairly high calorific value of the gas, a very small amt. of condensate in the gas-purifying app.; its drawbacks are its friability, difficulties of handling (which can be overcome by agglomerating, but this greatly increases the cost), large heat consumption in the carbonization of the wood, loss of over 33% of the available heat of the wood. The advantages of wood are that it is hard and non-friable, easy to handle, gives a gas with very high calorific value because it has a higher H content (in the case of dry hardwoods only), permits utilizing all the available heat of the wood; its drawbacks are variable compn. (white woods with high moisture content yield a gas with low calorific value), large amt. of condensate in the gas-purifying app., which chokes the piping or fouls the motor, useless transportation of H_2O and CO_2 . It was thought it might be possible to combine the advantages of the two and eliminate the chief drawbacks by carbonizing the wood at a temp. which would remove practically all the H_2O and the gases with low calorific value. I. **Study of the distillation of various woods at different temperatures.** *Ibid* 65-9.—The distn. tests were carried out in an electrically heated furnace holding 500-600 g. of wood (dried 2 hrs. at 100°), which could be heated to a uniform and closely regulated temp. With pine wood: (a) Up to 275° slow decompn. takes place, H_2O being evolved almost exclusively, and the gases contg. 75% CO_2 and 25% CO ; (b) toward 300° there occurs an exothermic reaction with evolution of large amts. of gas, pyroigneous acid and tar, the gases contg. 60% CO_2 and 40% CO ; (c) toward the end of the distn. (350 – 550°) there is a considerable decrease in the amt. of volatile matter given off, the proportion of CO_2 and CO in the gases decreases, and the proportion of hydrocarbons and H (which appear at about 325°) increases steadily; (d) analysis of the charcoal and calen. of its calorific value by Mahler's formula show that the final calorific yield (no. of available cal. in the charcoal from 1 kg. of wood) is completely preserved with carbonization up to about 275° , falls off sharply during the exothermic reaction at 300° , and then decreases progressively. The results indicate it would be advantageous to use wood carbonized a little below 300° , in motor-vehicle gas producers. A series of distns. carried out on ash, oak, poplar, elm and *Argania sideroxylon* showed that: (a) The general trend of the distn. is the same in all cases, there being an exothermic decompn. at 300° (at 350° in the case of *A. sideroxylon*); (b) the yields at the end of the distn. are all of the same order of magnitude, being approx. 12.5% gases, 40.0% pyroigneous distillate, 8% tar (except oak and ash which gave 2.50 and 3.40, resp.), 34.0% charcoal; the fact that the same yields of tar were obtained with the hardwoods as with pine is attributed to the fact that the pine used was low in resins (about 2%) and that the distn. was carried out rapidly and without overheating; (c) the compn. of the gases obtained at the various stages of the distn. is approx. the same for the different woods. The use of a catalyzer (impregnation with a 1% $NaOH$ soln.) did not affect the general trend of the distn., increased the yields of gas and of charcoal, and altered considerably the compn. of the gases as compared with that obtained from wood alone. The general trend of the distn. is the same in the case of cellulose and of lignin, the exothermic reaction taking place at 300° with cellulose and about 350° with lignin; lignin gives an appreciably higher charcoal yield and lower pyroigneous liquid and gas yield than cellulose, the nature of the gases produced at the various temps. being practically the same in both cases. II. **Tentative theory on the gasification of wood charcoal to determine the most suitable carbonization temperature.** G. DUPONT. *Ibid* 69-71. From theoretical considerations based on the results obtained in the above distns. D. concludes that: (a) The calorific value of the gas obtained in the producer is practically const. and max. for wood distd. at 100 – 200° , and the calorific value per cu. m. of cylinder volume of the motor, which is the most important characteristic from the standpoint of its utilization in the motor, follows a practically parallel curve. (b) The calorific efficiency in the motor, i. e.,

the no. of calories which can be obtained from 100 g. of the original dry wood, at the producer, at various moisture contents or for various degrees of carbonization, is also a max. for wood carbonized at 100–290°; it falls off sharply when carbonization is carried beyond the point of the exothermic reaction, and continues to fall off considerably as the carbonization temp. is increased. (c) The heat of combustion of the gas produced from 100 g. of charcoal, and also the vol. of the gases produced, increase progressively with the carbonization temp. These results clearly show the advantages of using wood carbonized at 275–90°; and it is hoped to give exptl. confirmation of these conclusions in the near future.

A. PAPINEAU-COUTURE

Boiler firing with simultaneous combustion of coal dust and (coke-oven) gas. A. SAUERMANN. *Glückauf* 64, 525–31(1928).—The burning of coal dust requires space not allowed for in the ordinary boiler installation, thus necessitating the attachment of an expensive combustion chamber. Diminution of this chamber is possible only by accelerating the time of combustion of the coal particle. To effect this, simultaneous combustion with coke-oven gas was tried, i. e., with a medium whose period of combustion is much less than that of coal dust. Sketches of the installation are given. The combination was tried on a tubular boiler whose steam output was 34 kg./sq. m. heating surface when the heat ratio of gas and coal dust was 1:2.74. When the heat ratio was 1:3.82, 29 kg./sq. m. heating surface was obtained with good utilization of the fuels and no added combustion chamber. Details of the steam trials are given including coal and gas analyses; gas pressure variations and heat balances. Curves for flame temp., raw-gas temps., % CO₂, steam pressure and steam temp. are given. These performances could be improved by various modification, for which diagrams are shown. Combustion took place with the combined fuels only in the tubes, whereas, before, much pre firing was necessary. A diagram of an app. for continuous removal of ash entrained from the tubes is given. The combination of fuels is suited for inclined-tube boilers and for foundries and the like. Very good results have been obtained with lean coal and although coke-oven gas was used in the tests, blast-furnace and producer gas could also be used if they and the air were preheated.

S. L. B. ETHERTON

Chart for finding heat loss due to incomplete combustion. C. A. KULMANN. *Power* 69, 473(1929).—A nomogram for facilitating estn. of heat loss due to incomplete combustion.

D. B. DILL

How much heat goes up the chimney? DAVID M. MYERS. *Power* 69, 437–40(1929).—Boiler losses are analyzed. Dry chimney loss is variable and can be reduced by stopping leaks, reducing draft and adjusting stoking until flue gases have a min. temp., max. CO₂ and no CO.

D. B. DILL

"Gasol" from low-temperature distillation gas, and low-temperature distillation gas for cutting and welding. H. SCHOLTZ. *Chem.-Ztg.* 53, 159(1929).—"Gasol," a mixt. of C₂H₄ and C₂H₆ with their higher homologs, has not given good results when used for welding purposes. This is due to the small explosive range when used with air—only 3.4–7.8%, approximating those of Et₂O (2.75–7.7%) and C₆H₆ (2.65–6.5%). When mixed with O₂ the explosive range increases to 3.4–43.2%. The addn. of C₂H₄ also proved advantageous, welds then being possible, and the cost being lower than with C₂H₂ alone as a fuel, as long as the iron is 6 mm. or under, but not with thicker material. Welding with low-temp. distn. gas alone required very much longer time than with C₂H₂, giving good welds nevertheless. This gas mixed with 20% C₂H₄ proved more economical than the C₂H₂ alone.

W. C. EBAUGH

A contribution to Feld's method for determining cyanogen compounds in washing liquors and hydrocyanic acid in illuminating gas. F. PERNA. *Plyn a Voda* 8, 139(1928); *Paliva a Topeni* 10(1929).—Feld's method gives good results with pure ferrocyanide, but with wash liquors the values are lower than the actual content of cyanogen in the soln. A certain quantity of the ferrocyanide does not dissociate, which can be confirmed by the green coloration of the distn. residue. Higher and more precise results are obtained if the alk. soln. is pptd. in the cold by adding drops of MgCl₂ and HgCl₂ with continuous stirring, washed into a distg. flask, and boiled 5 mins. This modification gives higher and more reliable results than Feld's method for determining cyanogen in illuminating gases.

FRANK MARSH

Heat value of natural gas on the basis of analytical results. WACLAW LESNIEWSKI AND KAROL KATZ. *Chem. Research Inst. (Poland). Przemysl Chem.* 11, 131–41, 294–7(1927).—Differences between values calcd. on the basis of compn. and exptl. calorimetric results amount to about 1%. It is quicker and simpler to calc. the fuel value of natural gas by the theoretical formulas here derived than to go through an involved analysis.

A. C. ZACHLIN

Chart for determining loss due to moisture in flue gas. C. A. KULMANN. *Power* 69, 543(1929).—Well-known formulas for this calcn. are expressed in a d'Ocagne nomogram.

D. B. DILL

Modern gas producers in the chemical and allied industries. WALTER KIRNICH. *Chem. Fabrik* 1929, 85-8.—Gas producers of the older types, with stationary grates, natural draft, etc., represent obsolete equipment, and ought to be replaced with modern producers, equipped with rotating hearths, automatic removal of ash, const. drive and mech. supply of air. Such generators permit the use of inferior grades and cheaper sizes of fuel, give cleaner ash, more uniform gas, afford quicker response to changed gas demands and are much more economical in operation. Illustrations and descriptions of Korting producers are shown, with general statements as to the efficiency of this type of plant. With auxiliary app. the thermal efficiency reaches 92.3%, and tar (low-temp. distn.) recovery 99% of the theoretical.

W. C. E.

Gas firing in central plants for heating and for preparing warm water. BATTIGE. *Apparatebau* 41, 33-4(1929).—A comparison of gas and coke; 1 kg. coke equals 0.8 cu. m. gas.

J. H. MOORE

The separation of tar clouds from gases. A. FISCHER. *Chem. Fabrik* 1929, 101-2.—A lab.-scale Cottrell app. was built from a chrome-plated steel pipe 50 cm. long and 50 mm. diam., provided with two 3-l. glass flasks attached to the ends. Through one set of openings in these flasks passed a wire 0.3 mm. directly through the pipe longitudinally, and the other pair served for the passage of gas under investigation. A 220 v. a. c. was stepped up to 10,000 v. by an oil transformer and then rectified by a "sending tube" (Firma Telefunken) whose filament was heated by a current from a 220-10 v. transformer. The pulsating 10,000 v. d. c. was connected with the wire passing through the steel pipe, while the steel pipe itself and the filament were grounded. Thorough cleaning of gas from tar was obtained, with gas velocities from 10 to 1500 l. per hr. passing through the app.

W. C. EBAUGH

The composition of tars from coals in northern Bohemia. BRĚTISLAV ŠIMEK. *Paliva a Topeni* 10, 157-60(1929).—Š gives tables of analysis of 12 tars showing the moisture content, source of coals, Engler distn., sp. gr., phenol and paraffin content. Seven tars were prepd. in the lab. by distg. 3 kg. of the lignite in an elec. furnace; 2 others were prepd. in a Fischer Schrader retort; the remaining ones were prepd. by firms in the northern district. A summary follows in French.

FRANK MARESH

Examination of tars from peat. G. I. STADNIKOV AND N. G. TITOV. *Brennstoff-Chem.* 9, 325-6(1928).—Three samples of peat dried to a 13% H₂O content were carbonized both in the Gracfe lab. app. and in the Fischer 25-kg. rotary retort. Yields by the former method were: coke 41.1, gas 24.3, tar 9.1 and H₂O 25.5%; by the latter: coke 42.0, gas 24.5, tar 12.0, and H₂O 21.5%. In both cases the figures are on the dry basis. Extn. of the peat with hot C₆H₆-EtOH soln. yielded 16.8% bitumen. Six % of the tar was insol. in (CH₃)₂O; 42% of this material (not carbon or peat dust) was sol. in pyridine. The portion sol. in (CH₃)₂O was distd. with steam and fractionated. It had a sp. gr. of 0.8567 and contained 0.48% bases and 2.4% tar acids. Of the tar 11.2% was a wax having an iodine no. of 44.6, sapon. no. 33.8 and acid no. 18.0. Asphaltenes (11.6%) and 13.8% resins were also found in the tar.

J. D. D.

Clean coke and its value. R. A. MOTT. *Fuel in Science & Practice* 8, 123-32 (1929).—Clean coke is of primary importance in blast-furnace use. Calcs. show that the C requirements of a furnace cause an increase in coke consumption of more than 1% when the coke-ash content is increased by 1%. Large-scale tests have shown that the saving in coke consumption per ton of pig for a reduced ash content of 1% averages approx. 0.4 cwt. A reduction of 1% ash in coke is worth at least 12¢ per ton of coke to the iron maker. Slurry produced in wet-washing may contain up to 25% ash. This product of the washery, often a large proportion, may be cleaned by the Rheolavener slurry washer, concg. tables or froth-flotation units. The practical working of these methods is discussed. Coke made from washed slurry is cheaper to transport, is of better quality, increases the output of the ovens and promotes the smooth working of a battery.

D. A. REYNOLDS

The new coking plant of the Lothringen Company. H. TRAMM. *Glückauf* 64, 719-29(1928).—The general layout is briefly described and a line plan is given. A somewhat more detailed account is given of (1) drying plant, (2) oven installation, (3) coke cooler, (4) by-product plant. The drying plant has a 3000-ton rotary drum, the inside of which has a coat of 2 mm. rustless steel to prevent corrosion. It is most economically heated by waste gas so that the coal entering with 12-14% moisture leaves with 6-7%. Reasons and advantages for this drying are discussed at length and the

economics of this operation are dealt with. The oven installation contains 60 high-production ovens in one setting, 54 being Koppers, for rich and poor gas, av. width 360 mm., 3730 mm. high, and 11,600 mm. between doors, capacity 10.2 tons dry coal, throughput period 11.5 hrs. Details of heating are described and also the discharging gear. Quenching can be done both dry and wet. The dry quencher will handle the complete 24-hr. throughput, *i. e.*, 1000 tons coke. The sensible heat in the coke is transferred to the inert gases of the waste-heat boilers where it is withdrawn and the waste gases are recirculated. A line sketch shows the coal tower, filling wagons, ovens, discharge machines, coke wagons, hot and cold gas mains, waste heat plant, etc. Cooling takes 4 hrs. Construction and other details are given. Dry-quenched coke has a better appearance, is stronger and larger and there is less breeze. Moreover, every ton of hot coke gives 0.39 ton steam. The economics of the installation are discussed. Some innovations were adopted in the by-product plant. The gas riser was as short as possible and lined with refractory to avoid tar condensation and consequent graphite deposition. The gas is water-sprayed to 150°, thus avoiding thick tar deposition. The gas is then washed to 85° and then cooled. The rest of the installation is described, including ammonia and benzene recovery and the related economics. The installation utilizes steam and vapor to the best extent, requires the least power, material and man power, and has utilized mechanical arrangements to the fullest extent.

Fuel. JULIUS THIECKE, MINIMAX A. G. and HERMANN HERZOG. Fr. 647,009, Jan. 12, 1928. A fuel is made by mixing NH_4NO_3 with an org. substance such as wood charcoal.

Gaseous fuel. LÉON MIRLESSE. Fr. 33,512, Jan. 29, 1927. Addn. to 608,620. An app. for gasifying heavy hydrocarbons for use in furnaces, motors, etc., is described.

Distillation of fuel. EUGÈNE HUREZ and PIERRE P. VIRELY. Fr. 33,609, May 27, 1927. Addn. to 620,307. A movable wall in the furnace chamber is moved up the sloping hearth to the charging opening; it is afterwards displaced progressively toward the lower end of the furnace as the charge enters.

Fuel briquets. A. L. J. VOINCHET and A. A. LERCIU. Brit. 297,085, Sept. 14, 1927. Fuels such as fine coal, sawdust, granular or powdered cork are mixed with kaolin, pipe clay or similar silicates or with mixts. which react to form similar silicates. Alk. silicates or substances reacting to form them are added during or after mixing and the mixt. is pressed into blocks and may then be treated with a reagent such as CaCl_2 to render the blocks resistant to moisture. In order to prevent superficial efflorescence, there may also be added acids such as HCl , H_2SO_4 , H_3BO_3 , H_2PO_4 , or formic, acetic or oxalic acid or glycerol or glucose.

New process for the gasification and utilization of fuel. J. BRAET, G. DE WILDE, P. WAUTERS, M. HERREBOUDT and E. MEIRLAEN. Belg. 352,163, July 31, 1928. Constructional features.

Externally fired horizontal retort for carbonizing solid fuel, etc. J. FENTON and

R. BAIN. Brit. 296,255, Jan. 24, 1928. A rotating retort is described which is preferably formed of steel and of truncated conical shape (material being fed in at the smaller end and discharged at the larger end).

Retorts for distilling carbonaceous materials. RICHARD B. PARKER. Fr. 647,765, Jan. 17, 1928.

Destructive hydrogenation. I. G. FARBENIND. A.-G. Brit. 296,431, Sept. 1, 1927. In order to obtain hydrocarbons of low b. p., coal suspensions, tars, oils or the like are treated with H in several stages under diminishing pressure. In treating American crude petroleum a pressure of 200 atm., a temp. of 450° and a catalyst contg. Mo and Cr may be used in the first stage.

Destructive hydrogenation. I. G. FARBENIND. A.-G. Brit. 296,700, Sept. 5, 1927. Oils of low b. p. are obtained from coals, tars and the like by subjecting the starting materials to a continuous cracking process with or without H under such conditions that carbonaceous deposits are formed with a minimum production of gas and then, in a second stage, treating the resulting products and carbonaceous deposits with H under high temp. and pressure in the presence of catalysts which may contain Mo and Cr.

Destructive hydrogenation. I. G. FARBENIND. A.-G. Brit. 296,984, Sept. 10, 1927. Motor fuels which do not "knock" are produced directly by the destructive hydrogenation of a liquid carbonaceous material mixed with another carbonaceous liquid adapted to produce aromatics, low-boiling and low-freezing hydrocarbons, naphthenes, etc., in which the products from the first-mentioned liquid would be deficient, e. g., liquid products from bituminous coal are subjected to destructive hydrogenation together with similar products from coals poor in bitumen, or crude petroleum and coal tar are destructively hydrogenated together (suitably at 460° under 200 atm. pressure), or crude petroleum and a liquid from the destructive hydrogenation of lignite are further destructively hydrogenated together.

Destructive hydrogenation. STANDARD DEVELOPMENT CO. Brit. 296,536, Aug. 8, 1927. A finely ground mass of solid carbonaceous material such as coal or a coke-like residuum is subjected to the action of a hydrocarbon oil and aq. liquid to sep. most of the ash, and the remaining carbonaceous material wetted with hydrocarbon oil is subjected to destructive hydrogenation (suitably at temps. of about 370-540° under 50-200 atm. pressure and in the presence of catalysts such as oxides of Mo or Cr). The product may be directly used as a fuel or may be mixed with fuel oil or may be distd. or cracked.

Destructive hydrogenation of coal, etc. I. G. FARBENIND. A.-G. Brit. 296,429, Sept. 1, 1927. Hydrocarbons of low b. p. are obtained by heating coal pastes, tars, oils or the like contg. large quantities of S and asphaltic substances with H and preferably catalysts in the liquid phase so that no destructive hydrogenation occurs and the S and asphaltic compds. are eliminated and then subjecting the material to a cracking treatment. A catalyst contg. Mo, Zn and Mg may be used for treating a "middle oil" with H at 430° and under 180-200 atm. pressure.

Hydrogenation of coal, etc. FRIEDRICK J. M. HANSEN. Fr. 617,981, Jan. 28, 1928. Coal, hydrocarbons or C are hydrogenated by the action of an elec. arc or sparks from a condenser discharge between electrodes immersed in a solvent for the products. One electrode is made of, or contains, a catalytically active metal such as Ni or contains a salt such as NiCO_3 which becomes dispersed in the liquid. Examples are given of the hydrogenation of coal and water gas.

Apparatus for distilling coal or other carbonaceous materials. PIERO M. SALERNI and EDOARDO M. SALERNI (to E. M. S. Industrial Processes, Ltd.). U. S. reissue 17,251, April 2. See original pat. No. 1,541,071 (C. A. 19, 2269).

Distilling solid carbonaceous materials. FABRIQUE NATIONALE DE PRODUITS CHIMIQUES ET D'EXPLOSIFS SOC. ANON. Brit. 296,443, Sept. 2, 1927. Before carbonizing coal, lignite, peat or oil shale, oxidizing agents such as oxides of Fe or Mn or carbonates of alkali metals or alk. earth metals are added to the charge. The yield of tar is increased and a porous coke is obtained which contains metal oxides or finely divided metals and may be used as a catalyst in synthetic processes such as production of condensable hydrocarbons and alcs. from CO, H and gaseous hydrocarbons produced in the distn. Pulverulent Fe ore, residues of roasted pyrites or Mn ore may be added and the residue together with the assocd. coke transferred to a reducing app.

Destructive distillation of coal, etc. P. DYORKOVITZ. Brit. 296,793, March 8, 1927. In a superposed retort system (structural details of which are described), coal or the like is distd. to obtain oils of the paraffin series by being first heated in the upper retorts and then passed into lower retorts and further heated to obtain heavier oils.

The retorts are externally heated by hot gases from a furnace and gases such as H₂, water gas, producer gas or coal gas are heated in a coil and passed through the charge (which may be agitated by a screw device).

Distillation of coal. IMPERIAL CHEM. INDUSTRIES, LTD. Fr. 647,604, Jan. 23, 1928. In the distn. of coal or the like by means of superheated steam, the steam coming from the retorts is cooled only to a certain extent, i. e., to a temp. well above condensation point, by means of water or oil. If water is used it is used in such limited amt. that it becomes wholly vaporized and the resulting oil is obtained free from water. The cooled steam is used as a source of heat for producing fresh steam.

Rotary retort for low-temperature distillation of bituminous coal. GABRIEL E. ROEMER (to National Coal Distillation Corp.). U. S. 1,708,740, April 9. Coal is fed through the annular chamber of an internally and externally heated horizontal rotary retort, the outer wall of which is provided with lifting baffles and the inner wall of which is provided with retarding baffles, and is alternately advanced and retarded and subjected to different degrees of distn. temp. from opposite sides of the annular distn. chamber, to produce gas and other by-products. Various details of the app. are described.

Carbonization of coal. COMPAGNIE HOUILLÈRE DE BESSÈGES. Fr. 647,112, May 27, 1927. See Brit. 291,341 (C. A. 23, 1249).

Coking coal. JOSEPH BECKER (to Koppers Co.). U. S. 1,707,427, April 2. A vertical and horizontally extended mass of coal is formed with a lower portion thinner than the upper portion and extraneously developed coking heat is applied to the sides of the mass during coking so that coking of the lower portion of the mass is accelerated and shortened relatively to the upper portion and the lower portion of the mass is completely coked before the upper portion. When the lower portion of the mass is substantially completely coked, steam is introduced into the lower portion until the upper portion is coked, thus increasing the gas production from the charge and retarding overcoking of the lower portion. An app. is described.

Device for burning pulverized coal in suspension in a current of air. JOHN VAN BRUNT (to Combustion Engineering Corp.). U. S. 1,707,335, April 2. Structural features.

Apparatus (with an oscillating screen) for washing coal, ores, etc. N. DESCAMPS. Brit. 297,330, Sept. 17, 1927. Structural features.

Briquetting coal fines, lignite fines, coke or semi-coke fines, etc. A. MEIRO. Belg. 351,793, July 31, 1928. The fines are worked into a paste with cereals, boiled vegetable oils and water, are pressed into briquets and dried. According to Belg. 351,794, the fines are mixed with Na silicate, powdered asbestos and water, pressed into briquets, and dried.

Removing soot from heating surfaces such as those of water-tube boilers, etc. GEORGE F. FENNO. U. S. 1,707,803, April 2. Soot is dislodged by gas eddies and vortices are produced by exploding a mixt. such as an explosive powder or air and gas which effects deflection of the normal flow of gases adjacent to the soot deposits which are to be removed.

Briquetting brown coal. MASCHINENBAU-ANSTALT HUMBOLDT. Ger. 472,462. July 10, 1926. The coal is disintegrated and the dust is sepd. from the granules. The dust is then briquetted without drying and the granules after drying.

Cooler for dried brown coal. WERSCHEN WEISSENFELSER BRAUNKOHLEN A.-G., MAX JASCHKE and FRANZ KIENAST. Ger. 472,397, Aug. 19, 1925.

Cooling plant for lignite. MASCHINENFABRIK HARTMANN A.-G. Ger. 471,538, July 13, 1927. The plant has a metal cooling column, at one end of which cool air is fed and at the other removed; the areas of the admitting and leading-off tubes are equal.

Peat. BOHUMIL JIROTKA. Ger. 471,607, Apr. 25, 1922. Pulp-like masses of peat are pressed through curved nozzles so that the material forms coils offering a large surface area to the drying air.

Peat. BOHUMIL JIROTKA. Ger. 471,608, Jan. 21, 1923. A device for the disintegration of peat comprises a milling cylinder in which rotates an axle with wave-like projections.

Peat. BOHUMIL JIROTKA. Ger. 471,609, Dec. 12, 1924. Addn. to Ger. 471,608. The ends of the rotating axle with the wave-like projections are provided with convex plates carrying brushes bearing against concave surfaces for assisting the milling and drying processes.

Apparatus for disintegrating and dewatering peat. ALLGEMEINE KOMMERZGES. A.-G. Ger. 472,342, Dec. 18, 1925.

Organic compounds from coal, tar, etc. I. G. FARBENIND. A.-G. Fr. 647,742, Dec. 16, 1927. Org. compds. of great value are obtained by treating coal, tar, wood, bituminous schists, etc., with hydrocarbons of high b. p. or high mol. wt. or their derivs. below the coking temp. of the hydrocarbons and at high pressure, and if necessary with the addn. of gases, with the exception of H, in appreciable amts., and catalysts. The products may be used for the production of *lubricating oils, Diesel oils or motor fuel.*

Chlorinated organic compounds for impregnating kindling materials. I. G. FARBENIND. A.-G. Fr. 647,656, Jan. 24, 1928. Org. Cl compds. such as tetrachloronaphthalene when used for impregnating papers, etc., for starting fires are rendered non-irritant to the skin by the addn. of non-irritant substances of a like phys. nature such as paraffin, waxes, rubber, gum and (or) alk. substances such as CaO , Na_3PO_4 , MgO , pyridine, tetrahydroquinoline and urea.

Gas. DAVID J. SMITH and REGINALD F. CLAYTON. Ger. 471,823, June 23, 1925. The plant has 2 coaxial gas chambers over which the fuel container is placed. Annular chambers surround these chambers so that the gas produced may circulate therein to preheat the fuel.

Purifying gas. JOSEPH N. REESON and WILLIAM L. MOSS. U. S. 1,708,590, April 9. Coal gas or the like contg. H_2S is treated with a soln. formed from a base such as Na_2CO_3 , an Fe salt such as the sulfate and citric acid.

Purifying gases. C. STILL. Brit. 297,061, Sept. 13, 1927. Gases contg. H_2S are treated with an aq. soln. of an alkali carrying in suspension an oxide or hydrated oxide of Mn or of both Mn and Fe. Brit. 297,062 specifies regeneration of spent gas purification liquors of this general type, with S recovery, by aeration with foam-producing materials.

Purifying gases. KALI-INDUSTRIE A.-G., C. T. THORSELL, and A. KRISTENSSON. Brit. 297,114, Sept. 16, 1927. H_2S is removed from gases by treatment with a suspension of basic ferric salts (such as a basic ferric chloride corresponding to the formula $\text{FeCl}_3 \cdot 6\text{Fe}(\text{OH})_3$) in a ferric salt soln. such as may be prepd. by oxidation of FeCl_2 with HNO_3 . S liberated in the gas purification is filtered out and the soln. reoxidized for further use.

Purifying fuel gases. J. H. BREGEAT. Brit. 296,925, Nov. 24, 1927. Gaseous fuel mixts. are brought into intimate contact with hydrogenated derivs. of naphthalene, hydrogenated cresols or hydrogenated terpenes, or their mixts., so as to retain impurities such as naphthalene, until the gas is cooled to effect their sepn. and condensation from the absorbing liquid. In order to scavenge distributor conduits, the purifying agent may be carried through them to absorb deposits. "Tetralin" (tetrahydride of naphthalene) may be used.

Mixed water gas and coal gas. CHARLES W. ANDREWS and HERMAN A. BRASSERT. U. S. 1,707,651, April 2. In generating mixed gas in a plurality of similar units, a procedure is followed comprising alternately air blasting and steaming through carbonaceous residue in certain of the units, passing the water gas generated through heated carbonaceous residue in another unit so that its temp. is raised, passing the heated gas through a body of fresh coal in the last-mentioned unit (so that volatile constituents from the coal are removed and mixed with the water gas), and agitating the mass of coal. Details of the app. are described. Cf. C. A. 23, 1497.

Gas producer. I. G. FARBENIND. A.-G. Brit. 296,713, April 2, 1927. Structural features.

Gas producer. I. G. FARBENIND. A.-G. Brit. 296,751, April 2, 1927. Details of construction of a producer are described which is suitable for use in a process in which a fuel gas is obtained by blowing air (or steam and air) through small-size ignited fuel with sufficient force to cause strong agitation of the charge. An auxiliary steam supply is provided for use when desired in producing water gas rich in H.

Gas producers. THE WELLMAN SMITH OWEN ENGINEERING CO., LTD., and ALFRED V. KEMP. Fr. 647,711, Jan. 26, 1928.

Lean-gas producer. E. WILLAUME. Belg. 352,060, July 31, 1928. Constructional features.

Continuous producer for mixed or double gas, for high- or low-temperature distillation with complete recovery of internal heat. H. J. M. WASTEELS. Belg. 351,527, July 31, 1928. Washed coal fines are introduced into a vertical retort by means of a rotary distributor. The bottom of the retort is sealed off by means of water, into which the coke falls and from which it is removed by means of an inclined worm conveyor. The retort is heated by means of compressed air and gas nozzles which are submerged under the water, and the air and gas are preheated in a chamber formed

by the inner wall of the retort and a surrounding wall made of suitable non-conducting material.

Gas producer construction (with separately rotatable fuel section and ash section). CHARLES W. LUMMIS (to Morgan Construction Co.). U. S. 1,707,811, April 2. Various structural details are described.

Gas retort assembly and regenerator construction. HEINRICH KOPPERS (to Koppers Development Corp.). U. S. 1,707,734, April 2. Various structural details are described.

Gas-making plant. PATENT RETORTS, LTD., and T. M. DAVIDSON. Brit. 296,161, July 2, 1927. In a complete gasification app. having a retort placed over a water-gas generator and externally heated by the gases generated, the generator and the checkered brickwork surrounding the retort are provided with one or more division walls and the charge leaving the retort is divided on entering the generator. Various other structural details are described.

Control for non-continuous water-gas generators. COMPAGNIE CONTINENTALE POUR LA FABRICATION DES COMPTEURS ET AUTRES APPAREILS and ALBERT BREISIG. Fr. 647,499, Jan. 19, 1928.

Valve control system for water-gas apparatus. WALTER BARR (to Western Gas Construction Co.). U. S. 1,708,375, April 9.

Timing devices for operating valves or other control mechanism of water-gas plants or similar apparatus. TULLY, SONS & CO., LTD., and L. DE REDON. Brit. 296,243, Dec. 30, 1927.

Montan wax. A. RIEBECK MONTANWERKE A.-G. Brit. 297,102, Sept. 16, 1927. In refining montan wax, it is deresinified (suitably by treatment with a solvent such as EtOAc) and is then refined with a solvent and decolorizing agent such as EtOAc or butanone and "Carboraffin" and fuller's earth.

Emulsions of tar, etc. HENRY BASSET and VICTOR SZIDON. Fr. 33,627, May 31, 1927. Addn. to 630,168. Emulsions of tar, asphalt, pitch, etc., which are insol. in water are made by using soap insol. in water as emulsifying agent.

Horizontal coke furnaces. CARL WESSEL. Fr. 647,599, Jan. 23, 1928. The method of heating is described.

Coke oven battery. JOSEPH VAN ACKEREN (to Koppers Co.). U. S. 1,707,419, April 2. Structural features.

Regenerative coke oven (which can be heated by "strong gas" or "weak gas"). CARL OTTO. U. S. 1,707,537, April 2. Structural features.

Coke oven construction (with a horizontal rotary drum and an interior tubular roller chamber). EMIL RAFFLOER. U. S. 1,708,152, April 9.

22—PETROLEUM, LUBRICANTS, ASPHALT AND WOOD PRODUCTS

W. F. FARAGHER

Position and problems of the oil industry today. AXTELL J. BYLES. *Mining J.* 164, 122-3 (1929).—B. discusses the present status of the industry—large amts. of available oil, increased gasoline production, oversupply of fuel oil, etc.—and forecasts the position of the industry for 1929. Demand for gasoline will probably be 408 million barrels, which can be supplied as follows: cracked, 142 million; natural, 37 million; imports, 10 million, and straight run, 219 million. The present production will meet these needs. Plans for rationalization are discussed. A. H. E.

Oil friction and flow orientation. S. KYRIPOULOS. *Z. tech. Physik* 10, 46-52 (1929); cf. *C. A.* 23, 1794. Dynamic viscosity changes, which are of great importance in lubrication, are largely due to orientation of the lubricant mols. in the direction of flow so that they assume positions of least mutual friction. The dynamic viscosity, therefore, depends on the force applied, decreasing with increasing force. If the temp. is kept const., the friction coeff., f , of a journal in a bearing depends on the velocity of rotation, U ; it decreases at first as the journal rises from the bottom of the bearing and the lubricating film becomes thicker. As this film, h , approaches half the clearance, f will increase with increasing dU/dh , the velocity gradient. The min. value of f is about 6% lower than the value for the journal at rest, f_0 . In the range of thin lubricating film (to the left of the min.) the so-called semi-liquid friction often occurs with considerable decrease in dynamic viscosity; for practical purposes a rather substantial film is most desirable; it eliminates the hazards of oil impurities and imperfect

bearing surfaces. Small castor oil addns. thicken the film considerably. From a mol. viewpoint the effects of various kinds of oil can be explained satisfactorily. Of the usual oil types, the highly viscous mineral oils with long mols. and large micellae ($d_{18} \leq 0.9$) will suffer considerable flow orientation at higher temp. and speeds; the medium to highly viscous oils of shorter mols. give less orientation, particularly if they are partly unsatd. ($d. > 0.9$); the sol-type oils consisting of a base oil with small mols. and addns. of very long mols. show orientation even at low speeds; non-viscous mineral oils with small mols. have little orientation; dipole oils, especially castor oil, with large complexes (dielec. const. = 4.65) orientate little. The stronger the tendency of an oil to become orientated (thin lubricating film by decrease in dynamic viscosity), the greater will be the effect of small quantities of inhibitors to orientation, e. g., castor oil which by its dipole qualities disturbs the orientated mol. groups and also adheres firmly to the walls. Possibly also the smaller compressibility of castor oil (close to that of water) causes the lubricating film to become thicker. At low temp., long-chain mineral oils (a "Valvoline" oil had a mol. wt. of 825) will give the desirable thick film for heavy load, at high temp. they will give low friction by decreased viscosity. They are, therefore, good for over-all use in explosion engines where both conditions occur. Recent work of Wolff on the exact detn. of the thickness of lubricating films by interference methods (Forsch. Arb. Gebiete Ing. Wesens, V. D. I. Verlag Berlin, 1928) largely corroborates the theory given here. From these observations (curves of h vs. T) it is again concluded that the film thickness is detd. by rotation velocity and dynamical viscosity, the latter depending on the former and on the temp. Rise in temp. will promote orientation by dissoen., but it also counteracts orientation by rotational heat motion of the mols., thus causing a max. orientation for a given velocity and temp. This max. is generally higher for heavy oils; it corresponds to a min. in h . Other points are discussed at length. B. J. C. VAN DER HOEVEN

Heats of combustion of petroleum oils. C. S. CRAIGIE, U. S. Bureau of Standards. (*Chal. et ind.* No. 102, 337-46 (1928)). A theoretical and practical study. C. used the Parr bomb of 400 ml. capacity. He shows how he corrected for (a) HNO_3 from the atm. N_2 , (b) HNO_3 from N_2 in the oil, and (c) H_2SO_4 from the S in the oil. If Q , is the total heat of combustion at const. vol. and d the sp. density at 15° , $Q_p = 12000 - 2100d$. The content of H is given by the equation $\% \text{H} = 26 - 15d$. C. gives tables and analyses of 50 fuels carried out by the U. S. Bureau of Standards, the heat of combustion of 36 petroleum products carried out by the U. S. Bureau of Mines, values of Constam and Schlapfer, values obtained by the U. S. Bureau of Mines on a no. of California crude oils, 70 values of Sherman and Kropff on petroleum oils, values of Ricardo, and heats of combustion of petroleum oils free from water, ash and S. A no. of plots are given and the analytical results are discussed. S. L. B. ETHERTON

Review of recent research in crude oil in Russia. IWAN YELIN. *Petroleum Z.* 25, 352-61 (1929). A short review of work done by Russian authors. A. A. BOEHLTLING

New process for separating heavy oil fractions. MAX MORGENTHAU. *Petroleum Z.* 25, No. 9, Special Section 3-4 (1929). A description of a new phys. chem. process, which is not disclosed, by which oils of a superior quality are obtained. Heavy bottoms are used for making high grade cylinder stocks from asphalt-base crudes, leaving an asphalt of gum-like consistency with a softening point of about 100° (Kraemer-Sarnow). An oil sepd. by the above process from Moreni residues is characterized in the table:

	Residue treated	Oil obtained
Sp. gr.	0.985	0.941
Viscosity E_{100} . . .	8.50	2.75
Solidifying pt. . . .	plus 10°	
Flash pt.	245°	245°
Hard asphalt.	7.5°C	0
Color	black	Dark greenish reddish brown.

A. A. BOEHLTLING

Continuous distillation of crude oil. S. VISHETRAVSKII. *Azerbeidzanskoye Neft-vanoye Khozyaistvo* 1928, No. 10, 55-66. Crude oil preheated in a vapor-heat exchanger enters through the upper part of a dephlegmator and is discharged into the first still of 3 sep. units from which it is led (in succession) through 2 other stills of each unit. The bottoms from the third still are pumped into the upper part of the second bubble tower and the reflux is sent through the fourth, fifth and sixth stills to the third tower; the oil from this tower flows into the seventh still. The final bottoms are withdrawn from the eighth still. The vapors from the first 3 stills enter the first bubble tower and are partly condensed and recycled; vapors from Stills 4, 5 and 6 are subjected

to the same operations in No. 2 bubble tower; and the vapors from Stills 7 and 8 enter No. 3 bubble tower. Good fractionation and economy in fuel are claimed.

A. A. BOEHLINGK

Air repressuring oil wells. G. SADOVNIKOV. *Azerbeidzhanskoye Neftyanoye Khozyaistvo* 1928, No. 6/7, 42-6.—The Marietta air-repressuring method was introduced on nearly exhausted oil wells in Ramanui; the yield in oil was increased 100% and in some cases even more. The oil so produced had an increased sp. gr., a change which is explained by oxidation due to injected air.

A. A. BOEHLINGK

Distilling Russian mazout. M. BESTUZHEV. *Azerbeidzhanskoye Neftyanoye Khozyaistvo* 1928, No. 10, 66-71.—Russian mazouts began to crack at about 350° in shell stills, which proved to be inferior to tube stills, and also when distd. at high vacua (up to 7 mm.). The f. p. of lubricating oils is higher when distg. with insufficient steam because the paraffin is transferred from the residue to the lubricating oil fractions. No formation of paraffin could be observed when oil products were distd. without steam.

A. A. BOEHLINGK

Emulsified and saponified oils. I, II, III. L. SINGER. *Petroleum Z.* 25, No. 7, Special Section 6-8; No. 9, Special Section 4-5 No. 12, Special Section 8-9(1929).—A review.

A. A. BOEHLINGK

Some characteristics of amorphous wax. LEO D. JONES AND F. E. BLACHLY. Sharples Specialty Co., Philadelphia. *Ind. Eng. Chem.* 21, 318-20(1929).—The various differences between cryst. wax and amorphous wax are described, as well as the various conditions whereby wax is pptd. in a petroleum lubricating stock in a cryst. or amorphous state. A surface tension and colloidal theory is proposed, to account for the occurrence of amorphous wax.

G. CALINGAERT

Comparison of methods for the determination of water in fuel oils. N. I. CHERNOZHUKOV. *Izvestiya Teplotekhn. Inst. (Tran. Thermo-Tech. Inst. (Russia))* 1928, No. 10, 11-2.—Dry oil was mixed with known quantities of water and the mixtures were analyzed by the method of Dean and Stark, which was found accurate within 0.2%, by that of Lissenko, which was rejected as giving errors up to 98%; by the centrifuge method, which was accurate within 1%; and by Denmark's method, which with paraffinic mazouts gave negative results for water content.

A. A. B.

The character of ground waters in Balakhanui. A. KREMS. *Azerbeidzhanskoye Neftyanoye Khozyaistvo* 1928, No. 4, 34-7.—Various theories on the location of water in different strata are discussed. The percentage compn. of water obtained from different depths is:

Depth of bore hole in meters	Cl	CO ₂	SO ₂	CaO	MgO
129.5	0.344	0.088	trace	0.0708	0.0238
279.2	0.51	0.186	trace	0.0116	0.0369
7.0	0.89	0.204	0.074	0.010	0.025
72.0	3.71	0.7	0.0524	0.0096	trace
193	3.12	0.518	0.048	0.0088	trace.

A. A. BOEHLINGK

Present tendencies of the cracking industry. ANDRÉ GAERTZ. Office nat. comb. combustibles liquides. *Ann. office nat. combustibles liquides* 3, 779-832(1928).—Thermal reactions of individual paraffin, olefin, acetylene, naphthene and aromatic hydrocarbons are reviewed (160 references). In addn., 18 references deal with asphalt and 37 with oxidation of gaseous hydrocarbons. G. urges cooperative research by the mining, chem. and refining industries in order to eliminate waste of petroleum products. The importance of the refining industry in relation to national defense is mentioned.

R. E. SCHAAD

Cracking petroleum. A. P. SACHS. *Chem.-Ztg.* 53, 65-6, 86-8, 107-8, 117-9, 167-8(1929).—A short incomplete review of the literature on cracking with particular reference to the Burton, Cross, Dubbs, Holmes-Manley and Richey processes.

D. F. BROWN

Selecting metal for cracking coils. I. ILOVAISKI AND L. DEMBO. *Azerbeidzhanskoye Neftyanoye Khozyaistvo* 1928, No. 4, 64-9.—Steel used in the drawn tubes of the Lomax cracking coil supplied to the Azneft had the following chem. compn.: C 0.125, Mn 0.52, Si 0.07, P 0.009 and S 0.028%. It was of fine ferritic-perlitic structure. A sample of a ruptured tube had a coarse Widmanstedt structure due to local overheating and still contained about 1% of C, a proof that the steel was heated close to its m. p., i. e., 1400-1450°. That it was not burned was proved by a heat-treating test, which converted the coarse structure to fine-grain. Mech. tests with new tubes

at temps. from 300° to 620° indicated that the safety factor fell nearly to zero at 610–620°. The proportional limit decreased from 16.1 to 2.2 kg./sq. mm.; the sp. elongation, from 26.7 to 42.1%; and the sp. contraction, from 57.1 to 98.1%. Conclusion: This steel is unsuitable for cracking coils. The use of Cr alloy steel is recommended.

A. A. BOEHLINGK

Vaporization of gasoline-benzene mixtures. N. I. CHERNOZHUKOV AND N. D. GRAMENETSKII. *Izvestiya Teploekh. Inst. (Trans. Thermo-Tech. Inst. (Russia))* 1927, No. 4, 19–24.—Vaporization tests conducted with various proportions of crude C_6H_6 and gasoline indicate that crude C_6H_6 can be used in a mixt. with motor gasoline. This C_6H_6 must be absorbed by solar oil and not by tar, as is usual; it must be free from naphthalene, treated with H_2SO_4 and NaOH, and the heavy ends (above 150°) removed. For mixing with Grozny aviation gasoline, the "120°" C_6H_6 should have no fractions above 120° and it must be acid treated and neutralized with caustic before blending.

A. A. BOEHLINGK

The determination of benzene, gasoline, alcohol and ether in liquid motor fuels. J. FORMÁNEK. *Chem. Obzor* 3, 4(1928); *Paliva a Topeni* 10(1929); cf. C. A. 22, 2826.—Some dyes, indanthrene dark blue BT, indanthrene violet RT, chlorviolanthrene, algol red B, algol red 2G and algol red 5G dissolve in benzene and color it and its homologs blue or red. In benzene the dyes are insol.; in EtOH and Et₂O only slightly sol.; and in tetralin they become sol. The powd. dye (0.01 g.) is added to the liquid, shaken well and filtered. The color gives a qual. test. For detn. the tetralin is sepd. by distg. at 170°, each fraction is tested separately. Aniline blue 2B is sol. in EtOH and colors it blue; its behavior toward aldehydes and ketones is the same; in benzene, gasoline, Et₂O and tetralin it is insol. Ether is detected with perchromic acid, which it colors blue. To 5 cc. of liquid are added 5 cc. of 1% $K_2Cr_2O_7$, a few drops of H_2SO_4 diluted 1:3, and 2 cc. of 3% H_2O_2 . The perchromic acid does not dissolve in hydrocarbons: alcs, aldehydes and ketones are also colored blue but the color soon changes to green or yellowish green. Ether is best detected in a fraction of b. p. below 40°. In a mixt. of alc., gasoline or benzene, the alc. is detd. in 100 cc. of the mixt. by adding 150 cc. of H_2O colored by fuchsin, and reading the vol. of uncolored liquid after shaking well, the difference is alc. In an alc.-Et₂O combination, 50 cc. of benzene is added to 100 cc. of the mixt. and diluted with 100 cc. of H_2O ; the change in vol. after shaking represents Et₂O. The upper layer contains 50 cc. benzene and the Et₂O to which a correction of 8 cc. is necessary for the soly. of Et₂O and H_2O . Benzene can be detected in a fuel if to 5 cc. of the unknown 3 cc. of aniline colored with aniline blue 2B is added and the mixt. heated. Upon cooling, the aniline seps. and the benzene remains uncolored. The sepn. of aniline occurs only if tetralin is absent and if the amt. of C_6H_6 , alc., or Et₂O is less than 35%.

FRANK MARESH

Knock ratings of pure hydrocarbons. A. W. NASH AND DONALD A. HOWES. Univ. of Birmingham, England. *Nature* 123, 276–7(1929).—The failure of chem. analysis of gasoline to indicate its knock value is due to the difference in knock values of the members of a given series. The antiknock values of some hydrocarbons were detd. by the bouncing-pin method. The following are cc. of ethyl fluid equiv. to 20% of the substance tested: cyclohexane 1, benzene 2.1, cyclohexene 2.4, toluene 2.75, 2-pentene 3.5, trimethylethylene 4.5, diamylene 6.0, diisobutylene 6.6. The diamylene is the olefin corresponding to Edgar's octane.

ARTHUR FLEISCHER

Instructions for laboratory tests of mineral-oil fuel. COMMISSION FOR THE UNIFICATION OF METHODS FOR LABORATORY TESTS OF FUEL. *Izvestiya Teploekh. Inst. (Trans. Thermo-Tech. Inst. (Russia))* 1927, No. 4, 77–96.—The following items are covered: fuel mazout, motor fuels, sampling from tanks, tankers and tank cars, and also from tanks in power plants.

A. A. BOEHLINGK

Paraffin plant in Grozny. A. ABLOVATSKII AND V. BRAZHNIKOV. *Azerbeidzhanskoye Neftyanoye Khoriyaistvo* 1928, No. 6–7, 59–68. The first paraffin plant built in Russia consists of two series of shell stills with four dephlegmators each. Grozny mazout is preheated by the bottoms from the last still, enters the first still, where its temp. is again raised, is then pumped to the following stills, losing successive fractions which are collected and form the "semi paraffin" stock. This stock is sent through a second series of stills in which it undergoes the same treatment. The oil so obtained is easily worked up in the paraffin presses at lower pressures than those normally used. The sweating operation is improved and a high-quality wax which could not be obtained through a single distn. of the mazout is obtained. A total of 40–45% of wax distillate is distd. from the mazout.

A. A. BOEHLINGK

Purification of lubricating oils by centrifuging. B. P. SVETLOV. *Izvestiya Teploekh. Inst. (Trans. Thermo-Tech. Inst. (Russia))* 1928, No. 10, 19–27.—The use of

centrifuges in various power plants for purifying used and fresh oil is described. Cost of equipment and savings in oil are given. A. A. BOEHLINGK

Carbonization of lubricating oils and fuel oils. N. I. CHERNOZHUKOV. *Thermo-Tech. Inst., Moscow. Ind. Eng. Chem.* **21**, 315-6(1929).—Under the conditions of the Conradson carbon-residue test, the carbonization depends on the amts. of asphaltenes and tars in an oil. Colorless oils and paraffins do not give appreciable amts. of coke when evapd. in the Conradson app. Conradson carbonization values are not representative of the carbonization of oils in service. More reliable information can be obtained by detg. the stability of the oils with regard to sludge formation. This method is based on the oxidation of oils by O_2 or air at high temps. and pressures. Different crude oils, lubricating oils and their tars give different amts. of sediment or sludge under the same conditions of oxidation. G. CALINGAERT

The structure of lubricating films and lubrication with colloidal graphite. H. KARPLUS. *Petroleum Z.* **25**, 375-86(1929).—The failure of the old hydrodynamic theory of lubrication is demonstrated and the latest investigations of the factors which control lubricating action are reviewed. An extensive list of references is given. It was found that colloidal graphite added to lubricating oils is better than fatty acids or other substances, because of the laminary structure of graphite and its chemical inertness. A. A. BOEHLINGK

Economical use of motor oil. KRONRAFF. *Petroleum Z.* **25**, No. 7, Special Section 9(1929).—Lubricating oil from motor-test benches is recovered mostly by centrifuging, heating, filtering and chem. treatment; it is then sent back to the crankcase or first mixed with fresh oil. The residue from used oil contains 77.5% of Fe, 17.7% of combustible material, 4.8% of ash, sand and sometimes up to 2.7% of water. The purified used oil has a slightly turbid appearance which does not affect its quality. A. A. B

Selection of the proper method for the determination of the oxidizability of transformer and turbine oils. N. I. CHERNOZHUKOV. *Izvestiya Teploekh. Inst (Trans Thermo-Tech. Inst. (Russia))* **1928**, No. 10, 13-8. The following tests and methods are briefly described: Waters method, Life test, Schwarz-Marcusson method, Stager method, the French method, the Italian method, the Belgian method, Michie sludge test, the Russian method (not described), the sludge accelerator test, Rogers and Miller method, the German method, Allgemeine Elektrizitäts-Gesellschaft method, Sligh test, and Butkov method. A. A. BOEHLINGK

Determination of the aging tendency of insulating and steam turbine oils. A. BAADER. *Reprint from "Elektrizitätswirtschaft." Communications* No. 461 and No. 463, 12 pp. (June, 1923). The aging of an oil is essentially an oxidation process which is accelerated by elevated temp. and by contact with certain materials, especially metals. There are 2 fundamental errors in the present methods of testing oils for their aging tendency, both in Germany and elsewhere. The first is, that all the causes of aging are allowed to act in combination upon a single sample of the oil being tested. The result is that the refiner does not know how to correct the technic of the refining process so as to produce an oil better adapted to its intended use. A Pb sensitive oil could be used in Pb-free units; a temp.-sensitive oil could be used where the temp. is always under 55°. The second error is, that movement of the oil while the test is in progress is entirely neglected, with the result that in order to accelerate aging, air or O must be conducted in or pressure applied, thus introducing conditions different from those under which the oil is normally used. A testing app. is described which avoids both errors. Four samples of the oil, held at the same temp. (95°) in a thermo-stat, are stirred continuously for 48 hrs. One stirrer consists of a glass spiral, one of Pb, one of Cu and one of Fe or of steel. At the end of the period the sapon no. and H_2SO_4 reaction are detd. for each sample of oil. The 2 detns. together require but a small fraction of the time and expense necessary for a tar-no. detn. The sapon no. for a sample stirred with glass spiral minus sapon no. for untreated oil represents the heat-sensitiveness of the oil; sapon no. for sample stirred with Fe minus that of sample stirred with glass represents the Fe-sensitiveness of the oil. Cu-sensitiveness and Pb-sensitiveness are found similarly. So also a set of sensitiveness figures is obtained based on the acid no. found for each sample. The acid no. is obtained by shaking 10 cc. of the oil with 10 cc. of 96% H_2SO_4 , letting stand for 3 hrs., and reading off the increase in vol. of the acid. The acid nos. found were low, making the percentage of error high. A table of data for 24 oils tested in the manner described is given, and the results are compared and discussed fully. The sensitiveness estd. from the acid no. did not always accord with that based upon the sapon no. The acid no. has for its basis only a part of the products of aging. Fe-sensitiveness is probably independent of temp.-sensitiveness. Fifty % of the oils were Cu-sensitive and 67% Pb-sensitive.

There is reason to believe that Pb-sensitiveness is acquired in some way in the refining process, and can therefore be prevented. An oil refined by the present-day Edeleanu process did not age half as rapidly as a H_2SO_4 -refined oil from the same crude.

EMMA E. CRANDAL

New Austrian standards (not yet accepted) for natural and mineral-oil asphalts. II. ÖNIG. *Petroleum Z.* 25, 404-10(1929).—The following items are included. (I) Sampling. (II) Phys. tests: (1) sp. gr., (2) breaking pt. by the Church method, (3) softening pt. by the ring-and-ball method, (4) penetration test, and (5) flash pt. (III). Chem. tests: (1) bitumen content, (2) water, (3) sulfur, (4 and 5) oil content and paraffin no., (6 and 7) acid no. and sapon. no., and (8) stability test. Nomenclature: (subdivisions according to origin). (I) Natural asphalts: (1) asphalts or mined pitches, (2) asphalts or glossy pitches, (3) asphalt minerals. (II) Mineral-oil asphalts. Characteristics: (I) natural asphalts, (II) mineral-oil asphalts. Testing: (I) Sampling. (II) Phys. tests: (1) density, (2) breaking test by the Church method, (3) softening pt. by the ring-and-ball method, (4) penetration test, (5) ductility, (6) flash pt. (III) Chem. tests: (1) bitumen content, (2) water, (3) ash, (4) S, (5) oil content by Marcusson and Eickmann method, (6) paraffin no., (7) acid no., (8) sapon. no., (9) stability, (10) adulteration test.

A. A. BOEHLINGK

The determination of the softening point of pitch and asphalts. A. SPILKER. *Z. angew. Chem.* 42, 263-4(1929).—Because of the possibility (rather remote, according to S.) of poisoning from Hg used in the conventional Kraemer-Sarnow method for detg. the softening point of pitch and asphalt, the suggestion has been made by Mallison, *et al.* that this standard procedure be replaced by some other, *e. g.*, "ball-and-ring," etc., method. But if this is done data now recorded will not be comparable with the newer detns.; to avoid this disadvantage and still get away from the use of Hg, S. recommends that a smooth Pb-Sb (80/20) rod, 5 mm. in diam. and weighing 8.0 g., hemispherical at the lower end and cut off straight at the top, be substituted for the 5 g. of Hg called for in the standard method, and that the instant when the rod, falling through the pitch, touches the beaker be taken as the end point. Some 15 series of comparative tests, involving 200 detns., are reported; they show deviations well within the limits of exptl. error, \pm , from -0.7 to $+0.7^\circ$.

W. C. BRAUGH

Determination of melting points in pitches and asphalts by the Kraemer-Sarnow method. D. HOLDE. *Petroleum Z.* 25, 411-2(1929).—Polemical discussion relating to the Hg method *vs.* the Cu-strip test.

A. A. BOEHLINGK

Fillers in bituminous materials. H. SUDA AND A. SCHMOLZER. *Petroleum Z.* 25, 351-5(1929).—Various proportions up to 70% by wt. of powd. brick, powd. lime, powd. granite, powd. quartz and asbestos were mixed with Trinidad pitch, coal-tar pitch and petroleum pitch. The customary phys. tests indicated that lime is unsuitable as filler for coal-tar pitch because of the free acid in the pitch, which reacts with the lime. Trinidad and petroleum pitch gave satisfactory mixts. for road pitch. Asbestos gave high elongation values because of its fibrous nature. Powd. quartz and granite behaved very much alike. A detailed report of further work will follow.

A. A. BOEHLINGK

Paraffin content of road asphalts. H. BURSTIN. *Petroleum Z.* 25, 257-60(1929).—Paraffin wax, which sometimes runs as high as 6% in artificial asphalts (Russian asphalts), was formerly considered undesirable in road asphalt; it does not affect the quality of asphalt, particularly if high-melting-point paraffin, which is elastic because of its noncryst. structure rather than brittle, is present. Three paraffin detn. methods were tried; preference is given to that of Marcusson, because it is considered the most accurate. Comparative tests of 3 different asphalts are given in the table:

	Paraffin content		
	"Mexfalt"	"Galbit"	"Molfalt" (asphalts)
Kraemer-Sarnow test	53°	49°	39°
Paraffin tests by:			
Schwarz	8.1%	0.10%	
Marcusson	5.5%	0.46%	0.22%
Cracking	6.2%	0.60%	0.35%

A. A. BOEHLINGK

Chemistry of road tar. H. MALLISON. *Petroleum Z.* 25, 399-403(1929).—Three sets of specifications for road tars adopted in Germany are given. They include "No. 1 coal tar," "anthracene-oil tar 60/40" and "anthracene-oil tar 50/50." The usual tests and characteristics in detail as well as a no. of photomicrographic reproductions of diluted tars are given.

A. A. BOEHLINGK

Trinidad asphalt in road-building. ANON. *Petroleum Z.* 25, 415-21(1929).—The asphalt shipped from Trinidad is purified before shipment; it has the following characteristics: CS_2 -sol. bitumen 56.5%, ash 38.5%, org. insol. compds. 5.0%, sp. gr. 1.40, softening pt. 85° , m. p. 112° , and penetration at 25° 4. This asphalt is mixed before use with mineral oil of the following specifications: sp. gr. at 15° 0.92-0.93, flash 177° , loss after heating for 7 hrs. to 162° , not more than 5%. Various methods of applying are described.

A. A. BOEHLINGK

Dust preventives on roads. W. v. PIOTROWSKI. *Petroleum Z.* 25, 260(1929).—"Drozol" tar oil, which is a soln. of petroleum asphalt in oil, is a suitable dust preventive, having a sp. gr. above unity, which prevents water from seepg. below the soln. It also has high penetrating ability, covering the pieces of gravel individually and filling the seams, whereby direct contact between the individual pieces is eliminated and friction decreased to a min. The life of the road is accordingly prolonged. The gravel road remains rough and the good traction insures the safety of vehicles even in damp weather.

A. A. BOEHLINGK

Ethyl alcohol from wood waste. FAUCONAU. Faculté des Sciences, Bordeaux. *Bull. inst. pin* No. 57, 57-61(1929).—The work of Kressman (*C. A.* 16, 2026) is reviewed. F. found that the optimum conditions for the saccharification of Bordeaux pine sawdust (the expts. described were carried out on 1 kg. of wood) were: dry wood 100, H_2O 200-400, HCl 2.5 parts, pressure 6.5 kg. per sq. cm., time of cooking 5 mins. After washing, the liquor is neutralized with NH_4OH and rendered slightly acid with AcOH . F. succeeded in fermenting 73% of the total sugars, with a yield of 100 l. of alc. per ton of dry wood.

A. PAPINEAU-COUTURE

Production of wood charcoal in the Landes forest. LOUIS DE LAPASSE. *Bull. inst. pin* No. 57, 71-7(Feb., 1929).—A discussion of the interest (particularly in France) in the production of wood charcoal, in the production at the present time, and in the possibilities of extending this production in the Landes forest.

A. P.-C.

Auto inflammability of different charcoals. HILDING BERGSTRÖM. *Jernkontorets Ann.* 82, 21-8(1927).—B. has examd. the O_2 absorption of different charcoals at 35° through a period of 2 yrs. The O_2 absorption is large for the first 50 days, but proceeds more slowly from that point, continuing, however, for more than 2 years. The results vary greatly for different charcoals. From 12 to 78 cc. of O_2 is absorbed per g. of dry charcoal in 500 days. Damp charcoal absorbs O_2 faster than dry. A. D.

Detection of adulteration of spirits of turpentine. (MISS) M. H. BARRAUD. *Inst. du Pin. Ann. fuls.* 22, 5-18, 83 90(1929).—The most reliable method is considered to consist in a distn. test, with sepn. into 5 fractions and examn. and comparison of the original sample and the 5 fractions: Place 200 cc. in a 500-cc. Pyrex flask surmounted by a 2-coil Lebel distg. column connected to a 90-cm. Liebig condenser and provided with a thermometer in the top of the column. The b. p. is taken as the temp. when the first drop falls into the receiver. Conduct distn. at the rate of about 1 drop per sec., collect four 40-cc. fractions (the 5th fraction being the residue in the flask) and det. d_{40} or d_{25} , n and acidity of the original sample and fractions 1, 3 and 5, and $[\alpha]$ of the original sample and all the fractions. The most valuable indications are given by the differences in d , n and $[\alpha]$ of the 1st and 3rd and 3rd and 5th fractions, resp. Numerous data are given from the results obtained with samples of known purity and different origins and also on samples adulterated in the lab. with known amts. of white spirit. The results give valuable indications as to the nature of the chief constituents of pure samples, and adulteration with as little as 2% of white spirit can be detected. The glycerol test (*C. A.* 22, 173) is described, explained, and discussed at some length. It is suggested the test might be improved by using powd. glass having the same n as glycerol, which renders the phenomenon much more brilliant. Massy's densimetric test (based on the difference in d of the sample as compared with 80.7% alc. by vol.) has the drawback of being applicable only to French spirits of turpentine. The turbidity test (temp. at which turbidity occurs in presence of PhNH_2) should be carried out on the various fractions obtained in the distn. test in order to obtain max. sensitivity: it can detect adulteration, but cannot det. it quantitatively. Detn. of ethylene linkages either by catalytic hydrogenation or by fixation of halogens may be of considerable value in scientific investigations, but is not practical in control methods. The Herzfeld method (detn. of residue unpolym. by H_2SO_4) gives fairly satisfactory results, but is considered rather long. Burton's method as modified by Marcussen (oxidation with fuming HNO_3 at -10° , cf. *C. A.* 4, 1541) is considered the most satisfactory method for the detn. of adulteration. The residue obtained on oxidizing pure spirits of turpentine consists of a thin, brown, oily film, free from foam when the result of the test is doubtful, by applying it to the 1st fraction of the distn. test.

adulteration may be detected with certainty and detd. quantitatively with sufficient accuracy for practical purposes. Salvaterra's method (C. A. 15, 1819) of oxidation by means of $\text{Hg}(\text{OAc})_2$ or yellow HgO in presence of AcOH is of particular interest for the analysis of kienöls. The work previously published (C. A. 22, 2659) on the Mau-mené no. is again described.

Spanish turpentine and their improvement. MARIANO TOMEO. *Servicio Forestal Investigaciones y Experiencias* 1, 98-108; *Pine Inst. Am. Abstracts*, Chem. Sect. 2, 184(1928).—The turbidity of Spanish turpentine is not eliminated by distn. *in vacuo* or in the presence of an inert gas. The efficiency of 12 filtering media is shown. The red color of Spanish turpentine is due to the presence of Fe 0.75 cc. of concd. H_2SO_4 in 7.5 cc. water completely decolorizes 600 cc. of turpentine and the oil is not unduly acidified by the process. The properties of turpentine from 4 species of Spanish pines were compared with those of Portuguese, French, American, Greek and Indian turpentine. The results show clearly that the production of Spanish and Portuguese turpentine, especially Portuguese, is not as efficient as to quality as the American and the French.

W. H. BOYNTON

The speed of an explosive wave (LAFFITTE, DUMANOIS) 24. The determination of alkali in seepage water [in oil wells] (MALYAROV) 7. Relation of diatoms to petroleum formation (v. STAHL) 8. Homogeneous catalysis [theory of anti-knock compounds] (EGERTON) 2. Organic compounds from coal, tar, etc. (Fr. pat. 647,742) 21. Tank and baffle plate construction for separating oil from water by gravity (U. S. 1,708,021) 1. Purifying oils (Ger. pat. 472,212) 27. Destructive hydrogenation (Brit. pat. 296,431) 21. Distilling solid carbonaceous materials (Brit. pat. 296,443) 21. Residues from lubricating oils for use on roads (Fr. pat. 647,897) 20. Emulsions of tar, etc. (Fr. pat. 33,627) 21. Centrifugal apparatus for purifying oils, etc. (Brit. pat. 296,670) 1. Overflow alarm device for filtering apparatus (U. S. pat. 1,708,235) 1.

Purification of petroleum. ALEXANDRE M. NASTYUKOV. Fr. 647,662, Jan. 24, 1928. Crude petroleum or its residues or derivs is purified by treatment with formol and concd. H_2SO_4 to form solid condensation products which absorb the satd. hydrocarbons. The reaction may be carried out in the cold or with heat, with or without a current of steam passing through the mass. The solid ppt obtained may be used for industrial purposes.

Cracking petroleum hydrocarbons. CHARLES R. DOWNS (to Weiss & Downs, Inc.). U. S. 1,708,303, April 9. Vapors from boiling S are used as a heating medium (out of direct contact with the hydrocarbon material) and the temp. of the S vapors is regulated by the pressure maintained on them. An app. is described.

Cracking petroleum oils. STANDARD DEVELOPMENT Co. Brit. 296,919, Oct. 22, 1927. Oil to be cracked and fractionated is passed through a heating app. such as a bank of tubes, thence through a heat insulated receptacle, and to fractionating towers connected in series. The last tower receives vapors near the middle point of its height and is provided with an independent reflux control at its upper end. Various details of operation are described.

Heating petroleum oils in pipe coils. JOHN C. BLACK (to Gasoline Products Co.). U. S. 1,708,076, April 9. In heating oil preliminary to distn. or for cracking, the oil is first passed through that part of a coil in the hottest portion of a furnace, thence, in the same direction as the combustion gases flow to heat the furnace, to the part of the furnace having the lowest temp. and then in a reverse direction to an outlet intermediate the zones of highest and lowest temp. An app. is described.

Treatment of acid sludge from the refining of petroleum oils by means of sulfuric acid. J. MASR. Belg. 351,175, June 30, 1928. After addn. of cold H_2O or dil. H_2SO_4 , hot air is passed through the sludge. The SO_2 evolved is recovered, the liquid is allowed to stand and the upper layer of sulfonated compds and the lower layer of H_2SO_4 are sepd. and recovered.

Cracking hydrocarbons. PAUL GRENFÉ. Fr. 33,504, Jan. 22, 1927. Addn. to 638,517 (C. A. 23, 274). Losses due to the formation of permanent gases are avoided by working in an atm. of industrial gases such as coke-oven gas, water gas, town gas, etc.

Cracking hydrocarbons. CHARLES P. TOLMAN. Fr. 617,721, Sept. 17, 1927. Hydrocarbons are cracked by vaporizing and mixing the vapors with superheated Hg vapor. A suitable app. is described.

Apparatus for distilling and other heat-treatment of hydrocarbons. I. G. FAR-BENIND. A.-G. Brit. 296,683, March 3, 1927. App. for processes such as distg,

extg., or dehydrogenating is formed of or lined with noble metals, ferro-Si, alloys of Cr, Mn, Mo or Co or steels contg. Cr, Mn or W, to prevent deposition of C. Catalysts used, if any, should be materials which do not promote C deposition such as silica, pumice, BaCO_3 , charcoal treated with Ba salts, W, B, etc., with or without a coating of lustrous C. Brit. 296,693 relates to the similar use of Al-lined or Al app. to prevent deposition of C. Brit. 296,694 relates to the use of app. coated with lustrous C for catalytic hydrocarbon treatment, cracking, etc.

Apparatus for high-temperature treatments of hydrocarbons. I. G. FARBERNIND. A.-G. Brit. 296,752, March 3, 1927. In order to prevent deposition of C on highly heated parts of the app., these are treated at high temps. with metalloids such as B, As, Sb, Bi, P, Se or compds. of any of these, or with Si. Small quantities of these are sufficient and they may be applied separately in the form of vapors or solns. of suitable compds. or may be supplied in the form of volatile compds. together with the hydrocarbons under treatment. An example is given of the treatment of a Cu tube with H_3BO_3 soln. before use for the catalytic conversion of C_2H_4 into C_6H_6 . Brit. 296,753 specifies app., the highly heated parts of which are formed of or lined with Mo, Ta or Cr to prevent deposition of C. Cf. Brit. 296,683 (preceding abstract).

Cracking hydrocarbon oils. EVELYN S. L. BEALE, GEORGE H. COXON and ALBERT E. DUNSTAN (to Anglo-Persian Oil Co., Ltd.). U. S. 1,708,782, April 9. Oil to be cracked is heated to cracking temp. while being passed through a pipe coil or like device of restricted cross-section, while subjected to the action of a feed pump and a surging pump which together impart both a generally forward feed and an alternately reciprocating movement to the oil stream, serving to check C deposition. An app. is described.

Cracking hydrocarbon oils. GUSTAV EGLOFF (to Universal Oil Products Co.). U. S. 1,707,348, April 2. Charging oil is brought into contact with evolved vapors passing through a dephlegmator and the charging oil and reflux condensate pass from the dephlegmator to an enlarged vaporizing zone counter-current to the flow of vapors. A pool of the charging oil and reflux condensate is maintained in the enlarged zone and preheated material from this pool is passed through a heating zone such as heating tubes where it is heated to a cracking temp. and thence to an independent pool in the enlarged vaporizing zone whence unvaporized residual oil is continuously withdrawn from the system but from which no oil is returned to the heating zone. An app. is described. U. S. 1,707,349 specifies heating the oil to a conversion temp. (suitably in a pipe coil) and then delivering it to an enlarged expansion zone where it overflows from one oil body to a second oil body, while removing vapors and subjecting them to reflux condensation and returning reflux condensate to the second body of oil; heavy C-contg. residue is withdrawn from the first mentioned body of oil in the enlarged zone and the second oil body in this zone is heated. Both this process and that of U. S. 1,707,348 are carried out under super-atm. pressure. An app. is described. Cf. C. A. 23, 2028.

Cracking hydrocarbon oils. EDWARD W. ISOM (to Sinclair Refining Co.). U. S. 1,708,180, April 9. A body of oil is maintained at a cracking temp. by circulating oil from the body through heating tubes and back to the body, vapors are taken off from the latter and the vapors are subjected to two successive refluxing operations, reflux condensate from the first refluxing operation is returned to the original body of oil, and reflux condensate from the second refluxing operation is forced through a sep. heating conduit and there heated to a cracking temp. and hot oil products from this heating conduit are discharged into the first-mentioned body of oil. An app. is described. Cf. C. A. 23, 2028.

Distilling hydrocarbon oils. FRANK B. FETTER (to National Refining Co.). U. S. 1,707,606, April 2. Oil to be cracked is rapidly impelled through a heater (which may be in the form of a pipe coil) under an extraneous pressure of approx. 1000 Ps. per sq. in. so as to attain a "working temp." for the oil of above 425° and graduated volumes of the hydrocarbon material are permitted to escape from the heater through an accelerating vent having the characteristics of a Venturi tube into a vaporizing chamber at approx. atm. pressure, and heavier and lighter products are sep'd. An app. is described.

Fractional distillation of hydrocarbon oils. JOHN PRIMROSE (to Foster Wheeler Corp.). U. S. 1,707,369, April 2. A batch of oil is circulated through a closed system comprising a storage tank and a fire-heated tubular oil heater with such velocity of flow through the oil heater as gradually to raise the temp. of the oil in the system, so as to keep the difference between the temp. at which the oil enters the heater and the temp. at which the oil leaves the heater small enough to permit the formation of relatively clean distn. "cuts," and not in excess of a predetd. and relatively small amount;

different vapor fractions successively liberated are withdrawn at successively higher temps. as the batch of oil is progressively heated. An app. is described.

Apparatus for heat conversion of hydrocarbon oils. JOSEPH B. WEAVER (to Gyro Process Corp.). U. S. 1,708,247, April 9. Liquid oil is heated in a pipe still and thence passed to an expansion chamber, vapors from the expansion chamber are subjected to heating to effect their conversion in the vapor phase and the same products used for heating the vapors are further used at a lower temp. for heating the oil in the still. The app. used is described.

Treating hydrocarbon oils with corona arc discharges. WILHELM ISMARCH (to Siemens & Halske A.-G.). U. S. 1,708,126, April 9. Hydrocarbon material such as oil is treated in the presence of air and between closely adjacent surfaces formed by water-cooled electrodes, with corona-arc high-frequency discharges produced by an a. c. of about 10,000 periods. Cf. C. A. 22, 4072.

Purifying oils. SIGBERT SEELIG. Ger. 472,070, Oct. 18, 1927. Hydrocarbon oils are purified by treatment with a plumbite soln. contg. free PbO in suspension.

"Soaking-drum" apparatus for cracking oils. HENRY H. HEWETSON (to Beacon Oil Co.). U. S. 1,707,520, April 2. Structural features.

Gasifying heavy oils. C. CHILOWSKY. Brit. 296,785, Sept. 8, 1927. See Fr. 640,686 (C. A. 23, 903).

Extraction of oil from oil sands by displacement. H. ATKINSON. Brit. 296,213, Oct. 10, 1927. A strong alk. soln. such as one comprising soap, soda ash and NaOH or KOH is used to displace residual oil. Various details of operation are given. Cf. C. A. 22, 682.

Digestion of bituminous shale, etc. WILLIAM H. HAMPTON. U. S. 1,707,759, April 2. Solid material such as bituminous shale is mixed with a mineral oil within the kerosene range and digested at a temp. sufficiently high to liquefy bituminous substances present and under sufficient pressure substantially to retard vaporization of the kerosene and heavier fractions, volatilized products are conducted away and recovered, and solid matter is sepd. from the residue of the digested mixt. An app. is described. Cf. C. A. 23, 2030.

Distilling mineral oil. ARTHUR E. PEW, JR. (to Sun Oil Co.). U. S. 1,707,448, April 2. Steam generated from deaerated water is used for distg. oil to obtain distillates of good color. An app. is described.

Oil-soluble sulfonates. HAYM E. BUC (to Standard Oil Development Co.). U. S. 1,707,506, April 2. In order to improve the color-stability when heated of the Na salt of an oil sol. sulfonic acid derived from the treatment of petroleum oil with a sulfonating agent, the salt is heated to above 150° in an alk. medium such as NaOH, 3%.

Paraffin. AKTIEBOLAGET SEPARATOR NOBEL and K. G. MALM. Brit. 296,805, June 7, 1927. Paraffin is sepd. from liquid hydrocarbons by pptg., dilg. and centrifuging in a separator having a mech. device for removing the ppt. The sepn. may be fractional, and portions of oil from which paraffin can be crystd. in an easily filterable state may first be removed by distn. Preferably the crude oils are distd. with steam and under reduced pressure, the distillate is dild., chilled slowly and centrifuged in a separator of a special type which is described. The sepd. paraffin is heated to remove solvent and then cracked to obtain a product sufficiently crystd. to be "sweated."

Lubricant. PRESTON C. GOSS. U. S. 1,708,058, April 9. A lubricant suitable for use in internal combustion engines comprises a petroleum lubricating oil mixed with an aq. ext. of the inner bark of slippery elm.

Lubricants. T. H. SANDERS. Brit. 297,201, Aug. 19, 1927. Lubricating oil for internal-combustion engines or other mineral, fatty or mixed lubricating oils have incorporated with them a small proportion of an org. ester such as AmOAc or Bu lactate, of low viscosity, to reduce the "oil drag" of the lubricant.

Lubricants for internal-combustion engines. STANDARD DEVELOPMENT CO. (FORMERLY STANDARD DEVELOPMENT Co.) and C. ARNOLD. Brit. 297,068, May 9, 1927. There is added to a hydrocarbon lubricating oil less than 0.5% of an alkali, alk. earth or other soap (such as a soap formed from corn oil, oleic acid and NaOH, or Na stearate or palmitate) and the mixt. is heated to above 175° but below the b. p.

Lubricating oil. JULES MORELLE. Fr. 647,501, Jan. 19, 1928. A lubricating oil is obtained by sapong. wool-grease pitch by NaOH lye, mixing with a coal-tar oil and adding fillers such as slaked lime, talc, etc.

Lubricating oils. HARALD NIELSEN and BRYAN LAING. Fr. 647,877, Jan. 13, 1928. An app. is described for distg. fuel to obtain crude oils which may be used to produce lubricants.

Lubricating grease from crank-case oil. EDGAR N. HILBERT. U. S. 1,707,633, April 2. After heating crank-case oil there is added to it a filler in powder form produced from NaOH 3, milk of lime 12 and a fat 15 parts, the agglomerate mass is agitated while heated and ignited to burn off the more volatile oils, and the remaining product is withdrawn for use as a lubricant. A heating and agitating app. is described.

Imparting a green fluorescence to lubricating oil stock. JOHN C. BLACK, WIRT D. RIAL and JOHN R. MCCONNELL (to Pan American Petroleum Co.). U. S. 1,708,563, April 9. Fluorescent substances are extd. from an uncracked petroleum pitch with the lubricating oil to be treated in sufficient quantities to give the oil the desired fluorescence.

Imparting green fluorescence to lubricating oil. WIRT D. RIAL and WHITFORD R. BARRATT (to Pan American Petroleum Co.). U. S. 1,708,592, April 9. In order to purify and improve the quality of lubricating oil contg. acid constituents, the oil is commingled with Ca(OH)_2 and a coal-tar pitch contg. green fluorescent substances at a temp. of about 110° or somewhat higher in quantities sufficient to neutralize and adsorb the acid constituents and add green fluorescent substances to the oil, and the oil is then sepd. from the excess of Ca(OH)_2 and coal-tar pitch residue.

Imparting green fluorescence to lubricating oil, etc. JOHN C. BLACK, WIRT D. RIAL and JOHN R. MCCONNELL (to Pan American Petroleum Co.). U. S. 1,708,602, April 9. A concd. ext. of green fluorescent substances is prepd. by extg. such substances from a coal-tar product with a mineral lubricating oil.

Refining used lubricating oils. ROBERT V. AYCOCK and WILLIAM D. HARRIS (to RefinOil Mfg. Corp.). U. S. 1,707,671, April 2. Used oil such as that from internal combustion engines which contains water and hydrocarbon diluents is heated to about 50° , H_2SO_4 is added to the hot oil, the mixt. is agitated and resultant sludge is removed, diluents are vaporized from the oil, and the latter is passed upwardly through an active adsorbent agent such as fuller's earth so that the latter is temporarily suspended in the oil; the suspended adsorbent is then allowed to settle as a cake and the oil is passed downwardly through this cake. U. S. 1,707,672 relates to an app. suitable for such filtration.

Regenerating lubricating oils. FIRMA HERMANN BENSMANN. Ger. 472,184, Mar. 26, 1926. See Brit. 268,284 (C. A. 22, 1233).

Apparatus for refining used lubricating oils. KARL GRIMM, MAX GRIMM and FRIEDRICH ANDERSEN. Ger. 472,439, Nov. 4, 1926. The app. is based on the observation that when used lubricating oils are heated to about 250° the oil ascends the sides of the heater while the impurities remain behind. The app. accordingly comprises a heater carrying a no. of arc-like plates, one end of each plate dipping into the oil in the heater and the other end being bent so as to deliver the rising oil to a collecting channel.

Apparatus for refining used lubricating oil by distillation and clarification. FRANK LIN O. KRIEGER (to RefinOil Mfg. Corp.). U. S. 1,707,673, April 2.

Reclaiming waste oils. RUDOLPH R. ROSENBAUM. U. S. 1,708,488, April 9. The alkali sol. content of used oil such as crank-case oil or transformer oil is saponified (suitably by Na silicate and a per-salt) and the saponified matter is withdrawn from the oil; fuller's earth impregnated with SO_2 is then mixed with the oil, and the oil is filtered to sep. the fuller's earth and adsorbed coloring matter and impurities. An app. is described.

Filter for lubricating oils, etc. OVE PETERSEN. Fr. 647,983, Jan. 28, 1928.

Filter for lubricating oil, etc. A C SPARK PLUG CO. Fr. 647,535, Jan. 20, 1928.

Bituminous emulsions. LESTER KIRSCHBAUM. U. S. 1,707,800, April 2. Emulsions which may be used with fibrous material for paper manuf. are formed of bituminous material such as asphalt together with a fluid vehicle such as water and colloidal clay or other emulsifying agent, and, after the emulsion is formed, there is added to it sol. salts such as Na_2SO_4 and ZnSO_4 , forming by chem. reaction *in situ* a protective coating for the emulsified particles without tending to change the size of the dispersed bituminous particles.

Colored bituminous compositions for making tiles, blocks, road surfaces, etc. F. MORYON. Brit. 296,626, Jan. 28, 1928. Coal-tar pitch or blast-furnace pitch having a "twisting point" between 40° and 65° is mixed with an aggregate of small chippings of granite and a filler (which may comprise sand and Fe oxides or limestone dust) suitable for making a product of the desired color.

23—CELLULOSE AND PAPER

CARLETON E. CURRAN

The effect of air on the processing of pure cellulose for fine quality viscose rayon. W. A. DYKS. *Chem.-Ztg.* 53, 185-6(1929).—By protecting alkali cellulose from CO_2 by known methods stronger filaments are obtained. Patent literature is reviewed, particularly with reference to American practice. A higher α -cellulose standard for the finished product is advocated.

Note on the dispersion of dissolved cellulose. H. ZEISE. Lab. I. G. *Kolloid-Z.* 47, 248-51(1929).—The conclusions of Hess (*C. A.* 18, 1381) regarding the presence of $\text{C}_6\text{H}_{10}\text{O}_5$ groups in cellulose-copper ammino hydroxide solns. are not justified. The value $\varphi = (\text{adsorbed copper})/(\text{rotation per millimol. of glucose})$ is not const. The copper adsorption isotherm shows two breaks, one of which appears to coincide with the disappearance of the characteristic x-ray spectrum of cellulose. FOSTER DEE SNELL.

Changes in sugar in the course of cellulose sulfite boiling. ERIK HÄGGLUND AND T. JOHNSON. *Svensk Kem. Tid.* 41, 8-11(1929); cf. *C. A.* 22, 866 (In German).—The decrease in sugar in sulfite liquors is due to the hydrolytic effect of the acids, dependent on the pH , and also to oxidation by HSO_3 ions, in which the CaO concn. is a factor. A. R. ROSE

Chlorination in the field of sanitation (ENSLAW) 14. Removing stains from paper (Belg. pat. 351,152) 13. Bituminous emulsions [for paper manuf.] (U. S. 1,707,809) 22. Forming interfelted laminated and compressed articles from pulp (U. S. pats. 1,707,429-30) 13.

Cellulose from beechwood, bamboo, etc. R. RUNKEL. *Brit.* 296,547, Aug. 24, 1927. Highly lignified plant material such as that of bamboo, beechwood, or other hard woods is comminuted and steeped or softened in hot or cold basic or acid liquors or boiled in water, then reduced to fiber by an edge runner or other suitable crushing app., compressed to a pulp or ribbon, impregnated with basic liquor, and then, as a pulp concn. exceeding 8%, is subjected to alternate chlorination and washing with alkali; after each washing it is treated in a centrifuge or worm press to secure the desired concn. Various details as to the use of Cl carriers such as SnCl_2 and of various softening agents are given.

Cellulose acetate. J. P. FOLCHI and L. J. DIDIÈRE. Belg. 352,522, July 31, 1928. Cellulose is dissolved in boiling glycerol, H_2SO_4 is added and the soln. is treated with Ac_2O vapors.

Cellulose acetate of high viscosity. HENRY DREYFUS. U. S. 1,708,787, April 9, 1928. Cellulose is esterified with a strong condensing agent such as Ac_2O and H_2SO_4 in the presence of a quantity of HOAc at least about 6 times the wt. of the cellulose.

Colored celluloid, etc. BADISCHE ANILIN & SODA-FABRIK. Fr. 33,596, May 21, 1927. Addn. to 588,903. Colored masses of celluloid and other cellulose derivs. are obtained by incorporating in the celluloid large amts. of dye in the manner indicated in the prior patent and then mixing with more uncolored celluloid or other plastic substances, in the presence or absence of solvents, till the desired color is obtained.

Artificial ebonite. KARL WEGNER. Fr. 644,011, Nov. 15, 1927. Derivs. of cellulose such as acetyl or nitrocellulose mixed with filling materials, solvents and softening agents, are submitted to a mech. treatment during which the mass is dried and reduced to fragments. Articles are made from the powder by pressing in heated steel molds, and may be used instead of articles made from ebonite.

Fireproofing cellulosic materials. H. PLATT and C. DREYFUS to British Celanese, Ltd.). *Brit.* 296,344, Aug. 29, 1927. Yarns, fabrics, paper, wood, or other materials are treated with solns., pastes, or other preps. of phosphoric acids, acid phosphates, arsenic acids, or stibinic acids; other fireproofing agents such as Al acetate may also be present in the prepn. used, which may also contain dyes. Various examples are given.

Artificial silk. ERNST GESSNER A.-G. Ger. 471,063, Dec. 4, 1926. A combined spinning and drying machine is described.

Artificial silk. HERMINGHAUS & Co. G. M. B. H. Ger. 471,61 Feb. 14, 1925. Porous or porous-coated spools for artificial silk are each connected to a sep. container so that the amt. and pressure of the washing fluid for the silk can be varied individually.

Artificial silk. J. P. BERNBERG A.-G. Fr. 647,001, Jan. 23, 1928. In the spinning

of artificial silk the troughs for the coagulating liquid are provided with narrow openings for the threads and are arranged to move to and fro in a horizontal direction transversely to the threads. The troughs may be provided with several compartments; the openings form guides for the threads. The liquid overflowing from the troughs is directed toward the cylinders on which the threads are being wound.

Artificial silk. I. G. FARBENIND. A.-G. Fr. 647,197, Jan. 14, 1928. Properties of artificial silk, such as extensibility, resistance to rupture and dye-absorbing properties, are improved by causing the thread after spinning to pass over guides, which alter the path of the thread on its way to the bobbins. Cf. C. A. 23, 702.

Artificial silk. NORDDEUTSCHE VERWALTUNGSGESELLSCHAFT M. B. H. Fr. 647,352, Jan. 9, 1928. See Brit. 283,481 (C. A. 22, 4246).

Artificial silk. OSCAR KOHORN & CO., and ALFRED PERL. Fr. 648,061, Feb. 1, 1928. In spinning and drawing artificial silk from cellulose in cuprammonium solns. the water used for pptn. of the threads is freed from NH_3 and Cu in known manner; after sepn. of the mud it is used again for pptn. To avoid accumulation of salts such as Na_2SO_4 or NaCO_3 , part of the water is replaced by fresh water each time.

Artificial silk from viscose. S. OHSAKA. Brit. 297,047, June 13, 1927. A soln. of an albumin assocd. with fatty oils, such as the protein of soy beans, sesame, earth nuts, or milk or blood-albumin is added to a viscose soln. in a proportion not greater than 20% the wt. of the cellulose used; the ripened soln. is passed into a coagulating bath, heated to 70-100° and then dried. Cf. C. A. 23, 278.

Artificial silk from cuprammonium cellulose solutions. C. R. LINKMEYER. Brit. 297,060, Sept. 13, 1927. Water used as precipitant in forming artificial silk filaments by the stretch-spinning process is subjected to a vacuum at a temp. somewhat above the temp. of the spinning bath to effect deaeration.

Washing, bleaching, desulfurizing and other treatments of artificial silk in the spinning boxes. I. G. FARBENIND. A.-G. Brit. 297,118, Sept. 15, 1927. An app. is described.

Spinning box for artificial silk manufacture. H. EGGERT. Brit. 296,253, Oct. 3, 1927. A bell member, which may be formed of Al, is detachably secured to a base of acid-resistant material. Various structural details are described.

Apparatus for producing artificial silk filaments. ERNST BERL. U. S. 1,707,595, April 2. Structural features.

Spinning pump for artificial silk. NAAMLOOZE VENNOOTSCHAP NEDERLANDSCHE KUNSTZIJDEFABRIK. Fr. 648,053, Feb. 1, 1928. Constructional details.

Apparatus for making artificial silk by the stretch-spinning process. BRYSIKA, LTD., and F. W. SCHUBERT. Brit. 296,856, July 15, 1927. Structural features.

Treating tubular cellulose articles (such as those formed from viscose) with cleaning baths. KALLE & Co. A.-G. Brit. 297,103, Sept. 15, 1927. The tubular material is passed successively around rollers within and above the cleaning bath, to lessen difficulties from development of gas within the material. An app. is described.

Paper. ANTON J. HAUG. U. S. 1,708,724, April 9. Mech. features.

Paper pulp. S. D. WELLS. Brit. 297,319, Sept. 17, 1927. In producing pulp suitable for the manuf. of paper as described in Brit. 285,277 (C. A. 22, 4817), a stronger pulp and better yield is obtained by increasing the ratio of dry pulp to water in the material treated in the rod mill to 7.5-9.5%. Structural features of a rod mill are described.

Paper-making apparatus. WALTER VOGEL (to the Firm A.-G. der Maschinenfabriken Escher Wyss & Cie.). U. S. 1,707,376, April 2. Structural features.

Paper-making apparatus. V. ANTOINE. Brit. 297,098, Sept. 15, 1927. Means are provided for applying coloring or sizing material over one face of the paper when passing to a distributing roller in front of pressure rollers. Various structural details are described.

Paper-making apparatus. CHARLES A. TIFFT. U. S. 1,708,434, April 9. A pipe discharges directly from a "Jordan" to a paper-making app.; the pipe is carried in a uniform pitch and the flow through it is controlled by a gate.

Apparatus and method of paper manufacture. JOHN TRAQUAIR (to Mead Pulp & Paper Co.). U. S. 1,707,333, April 2. A filter mat is formed of fibrous stock and tray water is caused to flow onto the surface of the filter mat. Various mech. details are described.

Wire gauze for paper-making apparatus. ALBERT ELSSENHANS. U. S. 1,707,757, April 2. See Brit. 266,931 (C. A. 22, 703).

Control mechanism for paper-making machines. JOHN WHITE. Fr. 648,058, Feb. 1, 1928.

Sizing paper. E. LECOCQ. Belg. 351,917, July 31, 1928. Sizing is carried out by means of a mixt. contg. an adhesive and a filler contg. 1 part of $Al_2(SO_4)_3$ and 2-3 parts of $NaHSO_4$.

Apparatus for regulating the density of paper stock. FRED B. WELLS (to Ohio Boxboard Co.). U. S. 1,707,966, April 2.

Tuning oscillatory electric circuit apparatus for determining the moisture content of paper, etc. ALBERT ALLEN (to Atlantic Precision Instrument Co.). U. S. 1,708,073, April 9. U. S. 1,708,074 also relates to similar app., which may be applied to the control of paper-making app.

Upright device for dissolving old paper. FRITZ PFEFFNER. Ger. 471,965, Dec. 3, 1925. Details of construction.

Paper containing bituminous material. LESTER KIRSCHBRAUN and ALBERT L. CLAPP (Clapp to Flintkote Co.). U. S. 1,708,926, April 9. Fibrous stock contg. a bituminous-pitch type base in aq. dispersion together with a dispersion agent such as colloidal clay is treated (suitably by adding Na silicate and alum) to cause the dispersed bituminous base to deposit in an unaltered state and to clot upon the fibrous stock solely by the addn. of reacting inorg. substances. U. S. 1,708,927 (LESTER KIRSCHBRAUN) specifies reducing bituminous material such as asphalt to relatively dry comminuted form, applying a protective coating, such as may be formed from Na silicate and Al sulfate, to the particles, mixing the product with fibrous stock and felting the stock to form a sheet.

Staining colors for printing paper. PAUL ROHLAND and FRITZ STOLZE. Ger. 471,931, Feb. 28, 1923. The raw material for the color is ground up with gypsum or marble to colloidal dimensions and added to the pulp in liquid suspension.

De-inking paper. HARRY C FISHER (to Richardson Co.). U. S. 1,707,604, April 2. In order to remove ink from fibrous pulp, the pulp is soaked in a soln. of alkali such as Na_2CO_3 to loosen the inky matter from the stock; it is then agitated with C_6H_6 or other suitable volatile liquid immiscible with water to form an emulsion contg. the inky matter; the volatile liquid is then vaporized, which causes the inky matter to float on the surface of the soln. whence it can be removed by skimming or spilling.

Renovating carbon papers. B. STÖCKEL and M. VON TENSPOLE. Brit. 297,309, Sept. 17, 1927. The paper may be passed in contact with an electrically heated cylinder maintained at a temp. of about 60-80° and thus subjected to heat and pressure without mech. rubbing. An app. is described.

24—EXPLOSIVES AND EXPLOSIONS

C. E. MUNROE

Explosives' aid to the hydrographic surveyor. D. L. PARKHURST. *Explosives Engineer* 7, 134-6(1929).—A bomb near the ship is fired, sending vibrations to the ship's hydrophone and to two off-shore hydrophones. The latter transmit the reception to their shore radio amplifying sets, which signal to the ship's chronograph the time of arrival of the sound on shore. By plotting the geographic point of the previously mechanically detd. depth the map sounding is obtained. Fulminate blasting caps, TNT and tetryl, in weak and strong bombs, gave no difference in amplitude or frequency of sound. TNT is considered safer. E. M. SYMMES

Influence of temperature on the formation of the explosive wave. P. LAFFITTE. *Ann. office nat. comb. liquides* 3, 499-501(1928).—See C. A. 22, 2665. R. E. S.

The speed of an explosive wave. P. LAFFITTE and P. DUMANOIS. *Ann. office nat. comb. liquides* 3, 121-2(1928); cf. C. A. 22, 1475.—Measurements made at initial pressures of 1 to 7 atms. in mixts. of H and O, CH_4 and O, and in similar mixts. contg. 0.1% of $PbEt_4$ show that the speed of propagation of the explosive wave is not affected by the antiknock compd. R. E. SCHAAD

New type of permissible explosive increases lump coal production. C. E. MUNROE. *Explosives Engineer* 7, 137(1929).—Reduction in d. of explosives involves the use of very light carbonaceous ingredients such as ground balsa wood, bagasse pith, ground corn stalks, ground oat hulls, dried beet pulp or pop corn, or using at a low temp. an explosive salt, an oxidizing salt, and a salt contg. H_2O of crystn. and impregnating absorptive carbonaceous material. The latter makes possible 500 cartridges $1\frac{1}{4} \times 8"$ per 100 lbs., a very high figure compared to that in 1909. E. M. SYMMES

Specifications for cellulose for use in manufacture of smokeless powder. FRED OLSEN. *Ind. Eng. Chem.* 21, 354-6(1929).—This is a detailed analysis of the specifica-

tion of the Ordnance Dept., War Dept. U. S. A., by comparison with data drawn from experience. It appears that much traditional misinformation encumbers the present specifications and that linters instead of being the best may prove an inferior source of the cellulose sought. The results are also published in the hope that those now engaged in the fundamental study of methods of processing cotton, or other forms of cellulose, may not be hampered by striving to have their products conform to present specifications.

CHARLES E. MUNROE

Nitrocellulose and smokeless powder. FRED OLSEN. *Army Ordnance* 9, 248-52 (1929).—Attention is called to the variability in compn. of dipping charges. A batch testing 12.65 N content actually consisted of material ranging from 11 to 13% N content. Even prolonged dipping failed to give complete uniformity. A reason for this is found in the physical variations in a mass of cellulose. The use of "popped" wood fiber is suggested as offering a greater assurance of uniformity. An app. for the purification of nitrocellulose by electro-endosmose is described. Many suggestions as to improvements in the methods of drying smokeless powder grains are offered and a new design for a solvent recovery box is presented.

CHARLES E. MUNROE

Decomposition of smokeless powder. C. G. STORM. *Army Ordnance* 9, 230-4 (1929).—Symptoms, causes and effects are discussed. The first factor is the instability of nitric esters due to impurities introduced by foreign substances present in the raw materials treated, or to products of nitration which produce N oxides; that, in the presence of air and moisture, act catalytically on the esters. The quantity of Ph_2NH introduced into the smokeless powder as a stabilizer has been raised from 0.5%, used during the war, to 1%. It cannot be increased above this because it affects the ballistics unfavorably and because the increased quantity decreases the stability of the smokeless powder. Because of the solvent left in the grains and the hygroscopicity of the latter the finished powder must be stored in hermetically sealed containers, in cool, dry, well-ventilated magazines. By making the grains non-hygroscopic the stability of the smokeless powder is much increased. Whether or not smokeless powder will be exploded spontaneously depends on a wide variety of conditions. Examples are cited of complete decomposition without explosion. Excellent photographs are given of grains in various stages of decomposition.

CHARLES E. MUNROE

Examination of BAm and BD Powders. M. DESMAROUX. *Mem. poudres* 23, 113-5 (1928).—Analysis of gases from the heated samples showed that the diphenylamine stabilized powders emitted 4 times as much NO_2 as did the Am alc.-stabilized powders.

A. J. PHILLIPS

Gaseous explosive reaction. A study of the kinetics of composite fuels. F. W. STEVENS. *Natl. Advisory Comm. Aeronautics Rept. No. 305*, 18 pp. (1929); cf. *C. A.* 22, 2058; 23, 516.—A series of studies of the kinetics of gaseous explosive reactions where the fuel, instead of being a simple gas was a known mixt. of simple gases, was made. In practical applications of gaseous explosive reactions as a source of power in gas engines the fuels used are composite, with characteristics that are apt to be due to the characteristics of their components and hence may be somewhat complex. The simplest problem in an investigation either of the thermodynamics or kinetics of the gaseous explosives reaction of a composite fuel is a sep. study of reaction characteristics of each component of the fuel and then a study of reaction characteristics of various known mixts. of those components forming composite fuels more and more complex. This order was followed.

E. M. SYMMES

Some properties of flame and combustion. W. E. GARNER. *Chemistry and Industry* 48, 186-9 (1929).—A review and discussion as to whether radiation from flames is due to thermal causes, i. e., the emitters of radiation are the mols. of CO_2 and water produced in the process of combustion as held by Paschen or due to chemi-luminescence as held by Pringsheim. O_2 and N_2 as gases were added to an explosive mixt. of $2\text{CO} + \text{O}_2$ and burnt in a closed cylindrical bomb fitted with a fluorite window, partial pressures being considered. The radiation fell on a thermopile attached to a galvanometer and was measured. The addn. of these gases increased the radiation, an effect contrary to that anticipated by Paschen's theory, as the inert gases added do not emit radiation themselves and would lower the temp. of the flame. The relationship between catalytic effect and the radiation emitted from flame was studied. A tabulation shows the effect of adding H_2 to a dry mixt. of CO and O_2 . Twenty % of the total chem. energy is emitted as radiation by carefully dried CO and O_2 . This is reduced to $1/4$ on addn. of 2% water or H_2 . This addn. must increase the temp. and hence be partly responsible for the increase in speed which occurs.

C. H. BADGER

Inflammability of hydrogen. VII. Dew point, density and range of inflammability of the treated hydrogen. YOSHIO TANAKA AND YUZABURŌ NAGAI. Tokyo Imp.

Univ. *Proc. Imp. Acad. (Japan)* 5, 80-1(1929); cf. *C. A.* 22, 2466. —T. and N. have calcd. the dew points and d. of H treated with explosion suppressors and give the results, with the range of inflammability as a table; the added compds. were: SnMe_4 , PbMe_4 , SeEt_2 , SeMe_2 , EtBr , C_6H_6 , C_6H_{12} , cyclohexane, Me cyclohexane, Et_2O and Me_2CO . SnMe_4 is the best explosion suppressor for H to be used in balloons or air ships; SeMe_2 and EtBr also are good, while Et_2O and Me_2CO are not suitable, owing to the phenomenon of the cool flame.

"Muditing" in coal mines. D. HARRINGTON AND F. E. CASH. *Bur. Mines, Circ. No. 6099*, 9 pp.(1929).—This report describes the use of "mudite," a mixt. of water and finely divided incombustible soil, or dirt, applied in some coal mines as a means of attempting to limit or prevent widespread explosions. It was tested out at the experimental mine at Bruceton. The final conclusion is that while muditing is probably more dependable than watering, especially in haulageways that also act as intake airways, it is probable that adequate rock-dusting methods would in the long run be more dependable and less expensive.

C. J. WEST
CHARLES E. MONROE

- Explosion in closed cylinders. I. Methane-air explosions in a long cylinder. II. The effect of the length of the cylinder.** WILLIAM A. KIRKBY AND RICHARD V. WHEELER. *J. Chem. Soc.* 1928, 3203-4.—The expts. were made in a gun-metal cylinder 200 cm. long, 10 cm. internal diam., having a capacity of about 16 l. with an igniting device at one end, a pressure gage at the other and windows at the side through which to view or photograph the phenomena taking place inside, and other devices to control the operations. Many are given but no general conclusions are presented. **III. Manner of movement of flame.** OLIVER C. DE C. ELLIS AND RICHARD V. WHEELER. *J. Chem. Soc.* 1928, 3215-8.—This presents an interesting series of photographs of flame produced in a cylindrical, horizontal tube as viewed through windows on the side of the tube which give much information as to the movements and changes in the structure of flames as they traverse the cylindrical vessel (cf. *C. A.* 22, 2841). C. E. M.

Granulating explosives. O. MATTER. *Brit.* 296,600, Nov. 25, 1927. An explosive substance to be granulated is dissolved in a solvent and the soln. is added to a liquid in motion which mixes in all proportions with the solvent but does not dissolve the explosive; e. g., a mixt. of pentaerythritol tetranitrate and tetranitromethylaniline is dissolved in acetone and the soln. in thin threads is run into water and the explosive sepd. and dried *in vacuo*.

Perchlorate explosives. C. G. LUIS. *Brit.* 296,794, March 9, 1927. In forming explosives contg. a perchlorate, there is used as an ingredient the husk or shell of *Terminalia chebula* which contains a relatively larger proportion of chebulinic acid than the other myrobalans. Other substances such as NaNO_3 , agar agar, castor oil, colza or rape oil, glycerol or a resinous gum such as red gum also may be added, and perchlorate of NH_4 , Na or K may be used.

Tracer composition for projectiles. STERNER ST. P. MEEK. U. S. 1,708,186, April 9. A tracer compn. is formed of an O-contg. compd. of an alk. earth metal, salts of a rare earth metal, a fuel and a binder, e. g., of Mg , BaO_2 , Yt and Zr nitrates, Ca resinate and Pb thiocyanate. U. S. 1,708,187 specifies a tracer compn. comprising Mg, a metal resinate such as Ca resinate and a Zn compd. such as $\text{Zn}(\text{NO}_3)_2$ and various other optional ingredients.

Igniting mixture for pyrotechnic or projectile tracer compositions. LOUIS HENDLER (to Secretary of War as trustee for the Government of the United States). U. S. 1,708,174, April 9. A peroxide of an alk. earth metal such as BaO_2 is mixed with Pb_3O_4 and a "metallic fuel" such as Mg.

- Pyrotechnic or projectile tracer composition.** HENRY C. PRITHAM. U. S. 1,708,151, April 9. Salts of Th and Ce, such as the nitrates, are used with Ca resinate or other suitable binder. $\text{Sr}(\text{NO}_3)_2$ and Mg also may be used.

Detergent for removing fouling from firearms. J. WAGNER. *Brit.* 296,550, Aug. 29, 1927. See *Fr.* 640,294 (*C. A.* 23, 985).

25—DYES AND TEXTILE CHEMISTRY

L. A. OLNEY

Interesting sources of natural dyestuffs. C. D. MELL. *Textile Colorist* 51, 188-90 (1929).—*Cassia fistula* is widely cultivated in tropical North Africa and throughout India for its bark, wood, gum, leaves, flowers and fruit. Its bark, commonly referred

to as "tanner's bark of cassia," is rich in tannin and is said to produce a bright red dye. The sap of the cujute tree (*Crescentia cujute*) is reported as a source of dye used by the early Spanish settlers in Panama for dyeing silk black. RUBY K. WORNER

Color chemistry and dyeing from the academic point of view. F. M. ROWE. *J. Soc. Dyers Colourists* 45, 5-10(1929).—See C. A. 23, 709. H. H. MOSHER

The colloid theory of dyeing. WILDER D. BANCROFT. *Am. Dyestuff Rept.* 18, 148-56(1929).—The dyeing of wool, silk and cotton is considered. In almost all cases if the amt. of dye on the fiber is plotted against the amt. of dye left in the bath, a typical adsorption curve is produced showing that compd. formation does not take place. Different behavior of different acids cannot be explained entirely on the basis of pH . Dyeing with acid and basic dyes, mordant dyes, substantive dyes, developed dyes, vat dyes, sulfur dyes, and inorg. dyes is explained by means of adsorption. Fastness to washing and light is discussed. The mercury-vapor lamp is not considered satisfactory for fading tests, because it does not give light comparable to sunlight. A plea is made for more systematic work on the action of light on dyestuffs. T. G. HAWLEY, JR.

The development of fast dyeing and dyes. JAMES MORTON. Morton Sundour Fabrics, Ltd. *Textile Recorder* 47, No. 552, 55-7(1929). RUBY K. WORNER

Package dyeing in circulating machines. HAROLD SCHROEDER. *Cotton* 92, 1019-20, 1065-7; *Ibid* 1242-4. Using direct colors in package machines. *Ibid* 93, 134-6(1928). Package dyeing of sulfurs in circulating machines. *Ibid* 93, 381-2, 437-43(1929).—Practical. RUBY K. WORNER

Tendered goods not always due to faulty dyeing. GEORGE RICE. *Textile Colorist* 51, 170-1, 174(1929).—A case of tendering of worsted fabric due to the overloading of virgin wool with reworked wool and mill waste is cited. An illustrated description is given of a device of the boring type for testing the wear-resisting qualities of cloth. RUBY K. WORNER

Shade matching in textile dyeing. NOEL D. WHITE. *Cotton* 93, 335 9(1929); cf. C. A. 23, 280.—Practical. Specific methods are given for matching shades. The sample is first matched in a beaker and from this the formula for use in the machine is calcd. RUBY K. WORNER

Selecting the proper dyestuffs. NOEL D. WHITE. *Cotton* 93, 453 4, 486(1929).—The testing for fastness to different conditions is discussed. RUBY K. WORNER

Thickening for vat print colors. L. S. BENDER. *Textile Colorist* 51, 169 70 (1929).—The thickenings in use are of a vegetable character and may be divided into 2 groups, starch or starch compds. and gum. Although either may be applied separately, the best results with vat colors are obtained by a combination of the 2 groups. Methods and formulas are given for prepg. thickenings. RUBY K. WORNER

Effect of twist changes on strength, feel and appearance of cotton yarn. A. A. MERCIER AND CHARLES W. SCHOFFSTALL. U. S. Bur. of Standards. *Textile World* 75, 1813-5(1929). RUBY K. WORNER

Determining the strength of the individual cotton fiber. HORACE L. PRATT. *Cotton* 93, 374-6(1929).—A detailed and illustrated description is given of the tentative method developed by the Bur. of Agr. Economics, U. S. Dept. of Agr. in cooperation with Clemson Coll. (cf. C. A. 23, 711). RUBY K. WORNER

Bleaching of cotton. WACLAW KACZKOWSKI WITH N. KROL. *Warsaw Polytech. Przemysl Chem.* 11, 568-81, 628 34(1927).—After the usual preliminary treatment with 1% H_2SO_4 at 25-30° the material is rinsed and boiled in 12 25% alkali, depending on the goods, kind of cotton, and final treatment. For white goods a 15-16% soln. is used; for those to be dyed later solns. up to 25% are used. The boiling is just above 100°; it is at atm. pressure and there is no exclusion of air beyond making sure that all goods are completely immersed. The boiling lasts 40-90 mins. The quantity of soln. need not exceed 200% of the wt. of the goods. The goods are next acidified with $HOAc$ or H_2SO_4 not over 25% at about 10° for 40-50 mins.; they are never allowed to be exposed to the air. After being rinsed again the goods are washed with a soap soln. at 50-60° and rinsed for the last time. The use of suitable wetting agents is very helpful in these operations. It should be borne in mind that concns., temps. and duration of treatment at the various stages depend on the goods and their eventual consignment. Fiber treated by this method has sometimes as much as ten-fold better susceptibility to certain dyes, especially the vat dyes, than that treated by the usual methods. Several advantages in mfg. are enumerated for this method of bleaching cotton. Cf. C. A. 23, 522. A. C. ZACHIN

Bleaching cotton with hydrogen peroxide. H. G. SMOLENS. *Am. Dyestuff Rept.* 18, 49-50(1929).—For bleaching ordinary American, Indian or China cotton, use silicate of soda and caustic soda (pH 12.0), $1\frac{1}{2}$ gal. H_2O_2 (100 vol.) per 100 gals. of water,

at 210° F. for 1½-2 hrs. Wet ratio of cotton to bleach liquor is not greater than 1:6.

Bleaching cotton goods in kiers with hydrogen peroxide. H. G. SMOLENS. *Am. Dyestuff Rept.* 18, 11-5(1929).—Factors involved in the kier bleaching of cotton with H₂O₂ by the one-boil and two-boil bleach processes are discussed. H. LEUPOLD

Hydrogen peroxide bleaching of wool, silk and cotton under chemical control. H. G. SMOLENS. *Am. Dyestuff Rept.* 18, 123-5(1929); cf. *C. A.* 23, 281.—Formulas are given for bleaching worsteds, silks and cotton under various conditions, together with the general method of controlling total alk., pH and peroxide. H. LEUPOLD

Treatment of wool with active chlorine in an organic carrier. G. L. ARMOUR. *Am. Dyestuff Rept.* 17, 819-20(1928).—Objections to the use of inorg. compds. of available Cl on textile materials, especially wool, for purposes of desizing, chlorination, etc., can be overcome by the use of aktivin, the Na salt of *N*-chloro-*p*-toluenesulfonamide. Some properties of the latter and a wool chlorination formula are given.

Woolen and worsted cloth analysis. II. GEORGE PRIESTLEY. Univ. of Leeds. *Textile Recorder* 47, No. 552, 49-51(1929).—The detn. of the basic material and its quality and the detection of the presence of reworked material are discussed. R. K. W.

Soaps used in the textile industry. THOMAS F. HUGHES. *Textile Colorist* 51, 160-3 (1929).—General. RUBY K. WORNER

A discussion of soap in its relation to the degumming of silk. IV. Double bath process for boiling-off silk. PROCTER AND GAMBLE. *Silk Degumming Bull.* No. 5, 9 pp.—The products of the degumming reaction and their influence in slowing the process are discussed. The double bath boil-off possesses a no. of advantages. Every batch of silk is thoroughly and uniformly boiled-off in respect to sericin and coloring material. Most of the gum is removed in the first soap. The fresh liquor used for the second boil does not become loaded with dissolved gum, color, oil and fatty acid from the decomposed soap. Oil spots are eliminated. The process requires 10% less soap than the single-bath boil-off. Also in *Textile Colorist* 51, 254-6(1929).

Dyes. I G. FARBENIND. A.-G. Brit. 296,373, Aug. 30, 1927. Halogenated anthranthrones (such as the mono- and di-bromo- and dichloroanthranthrones prep'd. as described in Brit. 287,020; *C. A.* 23, 524) are condensed with 1-aminoanthraquinone-2-aldehyde in the presence of an acid-absorbing agent and of a catalyst such as Cu, producing brown vat dyes.

Dyes. I G. FARBENIND. A.-G. Brit. 296,386, May 30, 1927. Vat dyes are formed by treating anthrapyrimidine, anthrapyrimidone, or their derivs. with alk. condensing agents and the products obtained from anthrapyrimidones, may be further treated with alkylating agents. All the products may be purified by treatment with oxidizing agents or by fractional pptn. from their solns. in concd. H₂SO₄. Several ex-

amples are given of the production of dyes which dye cotton from the vat orange, yellow or brown shades changing somewhat on exposure to the air.

Dyes. I. G. FARBENIND. A.-G. Brit. 296,473, June 1, 1927. Azo dyes are formed, in substance, on a substratum or on the fiber, by coupling a diazotized 2,5-dimethyl-4-haloaniline, in which one of the 3- or 6-positions is occupied by halogen and the other by H, with an arylide of 2,3-hydroxynaphthoic acid or of a β -keto-carboxylic acid. Examples are given of the manuf. of such dyes and of 2,5-dimethyl-4,6-(and 3,4)-dichloroaniline (which may be used as starting materials in making the dyes).

Dyes. I. G. FARBENIND. A.-G. Brit. 296,490, June 9, 1927. The action of acid condensing agents such as oleum, chlorosulfonic acid or AlCl_3 on *Bz*-1-2-methylbenzanthrone forms a mixt. of a black vat dye and the lactam of *Bz*-1-aminobenzanthrone-2-carboxylic acid from which the latter may be extd. by glacial HOAc or hot dil. caustic alkali soln.; this hydrolyzes the lactam to the free amino acid, which is then pptd. by acid. The pure lactam, extd. by org. solvents, may be similarly hydrolyzed.

Dyes. I. G. FARBENIND. A.-G. Brit. 296,616, Jan. 11, 1928. Azo dyes obtained by coupling *o*-hydroxydiazotized compds. with pyrazolones are converted into Cr compds. by heating them in aq. soln. under pressure, in the absence of a water-sol. org. solvent, with Cr compds. (such as the formate) in such proportions as to provide at least one atom of Cr for each chromable group of the dye molecule. An example is given of the chroming of the dye formed from diazotized 4-nitro-2-aminophenol-6-sulfonic acid and 1-phenyl-3-methyl-5-pyrazolone.

Dyes. I. G. FARBENIND. A.-G. Brit. 296,758, Sept. 7, 1927. Anthraquinone vat dyes are formed by treating a dye obtainable (as described in Brit. 12,921 of 1910 or 15,846 of 1909 or Ger. 240,080, C. A. 6, 2177 or Ger. 251,350, C. A. 7, 267) by condensation of 1,5- or 1,8-di- α -anthraquinonylaminoanthraquinone with concd. H_2SO_4 , dilg. with water and oxidizing (suitably with NaOCl).

Dyes. I. G. FARBENIND. A.-G. Brit. 296,817, June 10, 1927. Anthrone or its homologs or halogen substitution products are condensed with glyoxal or its bisulfite compd., sulfuric acid ester, or other compd. capable of giving rise to glyoxal, with or without use of a solvent or of an acid or acid-reacting salt. The products are vat dyes giving yellow shades on cotton. Examples are given of the condensation of anthrone and the chloroanthrone prepd. by reduction of α -chloroanthraquinone with glyoxal sulfate in glacial HOAc.

Dyes. I. G. FARBENIND. A.-G. Brit. 297,234, Oct. 25, 1927. Hydroxy and alkoxy derivs. of anthanthrone are formed by the action of acid condensing agents such as H_2SO_4 or ZnCl_2 and Ac_2O on hydroxy or alkoxy derivs. of 1,1'-dinaphthyl-8,8'-dicarboxylic acid; several examples are given of dyes of orange or violet shades. The 6,6'-dimethoxy deriv. of 1,1'-dinaphthyl-8,8'-dicarboxylic acid (one of the starting materials used) is made from 6-methoxynaphthostyryl, by hydrolysis, diazotization and treatment with ammoniacal Cu_2O . The 4,4'-dihydroxy deriv. is made by alkali fusion of the 4,4'-disulfonic acid.

Dyes. I. G. FARBENIND. A.-G. (Georg Kränzlein and Martin Corell, inventors) Ger. 472,135, Dec. 18, 1925. Acid dyes are prepd. by sulfonating *o*-aminoanthraquinonethiohydriens under sufficiently mild conditions to avoid the production of the corresponding thiomorpholines. Examples are given describing the sulfonation of 1-aminoanthraquinone-2-thiohydrin and 1-amino-4-*p*-toluinoanthraquinone-2-thiohydrin, the products dyeing wool red and blue, resp. The products from 1,4-diamino-2-chloroanthraquinone-3-thiohydrin (violet) and 1,5-diaminoanthraquinone-2,6-dithiohydrin (reddish brown) are also mentioned.

Dyes. I. G. FARBENIND. A.-G. (Max Weiler, inventor). Ger. 472,136, July 9, 1926. Ger. 423,093 describes the manuf. of chromable dyes by condensing 2,4- or 2,6-dihydroxybenzoic acid or its derivs. with aromatic aldehydes substituted (otherwise than with OH) in the *o*-position to the CHO group, the leuco compds. so obtained being worked up and, if desired, sulfonated. Ger. 430,832 modifies this process by using aromatic aldehydes unsubstituted in the *o*-position to the CHO group and also not contg. OH in the *p*-position thereto. It is now found that the dyes prepd. according to Ger. 423,093 and 430,832 are impure and can be sepd. from by-products by converting them into salts and sepg. the difficultly sol. salts of the dyes from the more easily sol. salts of the by-products. The purification of the dye prepd. from 2,6-dichlorobenzaldehyde and 2,4-dihydroxy-3-methylbenzoic acid is described by way of example.

Dyes. I. G. FARBENIND. A.-G. (Walter Mieg, inventor). Ger. 472,356, July 11, 1924. Dyes for wool are prepd. by treating dianthraquinonylamines with fuming H_2SO_4 under moderate conditions and, if desired, in the presence of H_3BO_3 or an *O*-carrier. The products are single oxidation products of the dianthraquinonylamino-

sulfonic acids formed in the first stage of the reaction. One example is given in which 1,1'-dianthraquinonylamine is treated with oleum at 120–125° for a long time with exclusion of moisture. The product obtained after dilg., salting out, etc., is a sulfonated oxazine of 1,1'-dianthraquinonylamine; it dyes wool in brownish violet shades not affected by mordanting or chroming. Other examples are given describing the manuf. of dyes from 1,2'-dianthraquinonylamine. In these examples, the treatment with oleum is effected in the presence of H_2BO_3 and HgO , and the products dye wool in dark violet and dark blue shades, resp.

Dyes. I. G. FARBENIND. A.-G. Fr. 647,514, Jan. 20, 1928. The monoazo dye from diazotized metallic acid and salicylic acid is heated with Cr formate and evapd. The chromed dye obtained dyes wool in pure greenish yellow shades, and may be used for printing cotton.

Dyes. KALLE & Co., A.-G. (Maximilian P. Schmidt and Otto Hermann, inventors). Ger. 471,637, June 7, 1925. An indigoid dye is produced by condensing the reaction products of sulfites on isatin α -chloride and its homologs or derivs., with compds. contg. the group $CH:C.OH$ or $CH_2.CO$. Thus, 1,4-bromonaphthol is dissolved in a dil. soln. of NaOH or Na_2CO_3 and a 10% soln. of the compds. resulting from the reaction of NaS and *p*-chloroisatin chloride added. A blue dye, 4-bromonaphthalene-2-*p*-chloroindoleindigo, is formed. If condensed with oxycarbazole, a black dye is formed.

Dyes. SOC. ANON. POUR L'IND. CHIM. À BÂLE. Brit. 297,002, Sept. 9, 1927. A benzanthrone is sulfonated with oleum at ordinary temp. and the sulfonic acid obtained is fused with caustic alkali at a temp. of 255–310° to produce a vat dye which may be alkylated. Examples are given of gray and blue dyes.

Dyes. SOC. ANON. POUR L'IND. CHIM. À BÂLE. Fr. 647,943, Jan. 30, 1928. New dyes are obtained by treating 1-hydroxy-, or 1-alkoxy-, or 1-amino-4-aminoanthraquinones with aromatic diamines or their derivs. or substitution products. Thus, 1-methoxy-4-aminoanthraquinone is heated with *p*-phenylenediamine and $PhNMe_2$ giving 1-(*p*-aminophenylamino)-4-aminoanthraquinone, m. 247–248°. It dyes acetate silk or varnishes fast bluish green shades. 1-Hydroxy-4-aminoanthraquinone and *p*-phenylenediamine give the same product and this may be sulfonated with oleum, giving a product which dyes wool greenish blue shades. *p*-Phenylenediamine may be replaced by dimethyl-*p*-phenylenediamine, *m* toluylenediamine, benzidine or 5-amino-2-methylbenzimidazole.

Dyes. SOC. ANON. POUR L'IND. CHIM. À BÂLE. Ger. 472,210, April 29, 1927. Vat dyes giving blue shades on cotton are prepd. by sulfurizing the leuco compds. of indophenols prepd. by condensation of nitrosophenols with carbazoles, the sulfurization being effected in the presence of an aliphatic nitrogenous compd. and, if desired, of an aromatic base and (or) a substrate. E. g., the indophenol prepd. by condensing nitrosophenol with carbazole is reduced with Na_2S_2 soln. and the product is sulfurized in the presence of $CNNH_2$ and NaCl. Instead of $CNNH_2$ there may be used $CO(NH_2)_2$, $NH_2CONHNH_2$, $CS(NH_2)_2$, $AcNH_2$, NH_4CNS , or salts of $NH_2C(NH)NH_2$. Examples are given also in which an aromatic base, viz., carbanilide or di-*o*-tolylurea, is also present during the sulfurization. The manuf. is described of dyes from condensation products of nitrosophenol with a mixt. of carbazole and *N*-ethylcarbazole.

Azo dyes. I. G. FARBENIND. A.-G. (Bartholomäus Vossen, inventor). Ger. 472,488, Aug. 20, 1926. See Brit. 276,353 (C. A. 22, 2470).

Azo dyes. I. G. FARBENIND. A.-G. Fr. 647,618, Jan. 23, 1928. Azo dyes insol. in water are produced in substance or on the fiber by coupling arylamides of 2,3-hydroxynaphthoic acid with diazo compds. of those *as-m*-xylinides which carry in the *m*-position another amino group, the H atoms of which may be replaced by alkyl, aralkyl, benzoyl or arylsulfo groups. In examples, cotton is impregnated with benzoylamino-*as-m*-xylinide hydroxynaphthoic α -naphthylamide and developed with benzoylamino-*as-m*-xylinide ($NH_2, CH_3, CH_3, NH-CO-C_6H_5 = 1,2,4,5$); (2) 2,3-hydroxynaphthoic 5-chloro-2- $(NH_2, CH_3, CH_3, NH-CO-C_6H_5 = 1,2,4,5)$; (3) 2,3-hydroxynaphthoic 5-toluidide and developed with methylbenzoylamino-*as-m*-xylinide ($NH_2, CH_3, CH_3, NH-CO-C_6H_5 = 1,2,4,5$), or dichlorobenzoylamino-*as-m*-xylinide ($NH_2, CH_3, CH_3, NH-CO-C_6H_3Cl_2 = 1,2,4,5$), or developed with methyltoluene sulfamino-*as-m*-xylinide ($NH_2, CH_3, CH_3, N.SO_3, C_6H_4, CH_3 = 1,2,4,5$). Red or bluish red dyes are obtained in each case.

Azo dye. SOC. ANON. POUR L'IND. CHIM. À BÂLE. Ger. 472,355, July 13, 1926. Diazobenzene is coupled with 1-(2-chlorophenyl)-3-methyl-5-pyrazolone. An aq. suspension of the product gives yellow shades on cellulose acetate. Cf. C. A. 23, 1261.

Vat dyes. I. G. FARBENIND. A.-G. Fr. 647,509, Jan. 19, 1928. Vat dyes are obtained by submitting an arylthioglycolic acid mixed with a condensable diketone or its derivs. to the action of P_2O_5 . Thus, a mixt. of P_2O_5 and silicic anhydride is added to a

heated soln. of 1-chloronaphthalene-2-thioglycolic acid and isatin in dichlorobenzene. The product obtained dyes fiber Bordeaux-red shades from the vat. A product giving brown shades is obtained in the same way from α -naphthylthioglycolic acid and 5,7-dibromoisatin in PhCl, and a red dye is obtained from 6-methyl-4-chlorophenyl-1-thioglycolic acid and acenaphthenequinone in PhCl.

Vat dyes. I. G. FARBENIND. A.-G. Fr. 647,736, Dec. 1, 1927. New vat dyes are obtained by halogenating the 8,8'-dihydroxy-1,2,1',2'-dinaphthazines or their acyl derivs. preferably in the presence of a diluent and a catalyst, and removing the halogen as halogen acid. Thus, 8,8'-dihydroxy-1,2,1',2'-dinaphthazine is boiled with Ac_2O and Cl is passed in. The product which is pptd. by the addn. of water contains 8 to 10 atoms of Cl in the mol. If dissolved in H_2SO_4 , HCl is given off and the product obtained on diln. with water dyes cotton in fast red shades from the vat. Several other examples are given.

Anthraquinone vat dyes. I. G. FARBENIND. A.-G. Brit. 297,133, June 11, 1927. AlCl_3 fusions of anthraquinone derivs. for prepg. vat dyes are carried out in the presence of an aromatic tertiary base such as pyridine, quinoline or dimethylaniline (which is preferably first mixed with the AlCl_3 to form a compd. sol. in an excess of the base). Examples are given of the manif. of flavanthrone from β -aminoanthraquinone and of the manif. of other vat dyes.

Preparations of leuco compounds of vat dyes. J. R. GRIGY A.-G. Ger. 472,341, Aug. 17, 1926. See Brit. 276,023 (C. A. 22, 2471).

Azine dyes. BRITISH DYEING CORP., LTD., and W. A. SILVESTER. Brit. 296,803, June 7, 1927. Substantive cotton dyes which also dye regenerated cellulose and are substituted ureas are formed by the action of phosgene upon acid wool azine dyes having a primary or secondary amino group. Examples are given of the production of the dyes and of starting materials used.

Indigoid dyes. BERTRAM MAYER and JAKOB WÜRGLER (to Soc. anon pour l'ind. chim. à Bâle). U. S. 1,707,918, April 2. A large number of examples are given of the production of dyes of the general formula

wherein one of the two x 's stands for a S atom and the other for a CO group, z for a H or an O atom and m , n and q for 3 members of a 5-membered nucleus of which 2 at least are C atoms adjacent to each other and belonging to an aromatic system, the third being S, NH or C, which products form yellowish green to gray, brown, violet and black powders, dissolving in concd. H_2SO_4 with yellowish green to green, blue and violet coloration which are more or less bright or blackish, in dil. caustic soda soln. on addn. of hyposulfite with yellow-brown to olive and bluish red coloration, dyeing cotton green to brown, Bordeaux, violet and gray fast tints. A table is given showing properties of 38 different dyes made from various components and numerous details and modifications of procedure for making the dyes are described.

Sulfuretted dyes. I. G. FARBENIND. A.-G. Brit. 297,123, Sept. 15, 1927. The indophenols and leuco indophenols prepd. as described in Brit. 285,382 (C. A. 22, 4833) are subjected to polysulfide fusion. Examples are given of dyes producing bluish violet and green shades on cotton.

Sulfuretted dyes. I. G. FARBENIND. A.-G. (Erwin Kramer, inventor). Ger. 472,357, Aug. 18, 1926. See U. S. 1,675,498 (C. A. 22, 3304).

Sulfuretted dyes. I. G. FARBENIND. A.-G. (Erwin Kramer, inventor). Ger. 472,358, Aug. 18, 1926. See U. S. 1,675,499 (C. A. 22, 3304).

Triphenylmethane dyes. FARBENFABRIKEN VORM. F. BAYER & Co. June 17, 1927. Fr. 33,689, addn. to 593,774. The dyes obtained according to Fr. 593,774 by condensing 2,4- or 2,6-dihydroxybenzoic acids or their mixts. with aromatic aldehydes and oxidizing the resulting leuco compds. are converted into their salts, and the difficultly sol. pyrone salts are sepd. from the more easily sol. accessory products.

Substantive dyes of the stilbene series. ALFRED RHEINER (to Chemische Fabrik vorm. Sandoz). U. S. 1,708,897, April 9. See Brit. 263,792 (C. A. 22, 170).

Dyes of the anthraquinone series. FARBENFABRIKEN. VORM. F. BAYER & Co. Fr. 33,541, May 18, 1927. Addn. to 567,767. A better result than that obtained in the prior patent is secured by carrying out the process as follows: 10 parts of 1,1'-dianthraquinonylamine is dissolved in oleum contg. 15% SO₃ and heated to 95–100° until a sample is completely sol. in water with a brownish yellow color. The cooled mass is poured into 600 parts of water, boiled, and the dye pptd. by the addn. of salt and washed.

Metal compounds of dyes. SOC. ANON. POUR L'IND. CHIM. À BAËLE. Brit. 297,003, Sept. 10, 1927. Disazo and polyazo dyes contg. metals such as Cu or Cr are obtained either by introducing the metal into a dye formed as an intermediate or by treating the finished dye with an agent yielding one or more metals. In some cases coupling may be effected in the presence of a reagent yielding one or more metals. Several examples are given of the use of Cu, Cr and Ni compds.

Metal compounds of azo dyes. SOC. ANON. POUR L'IND. CHIM. À BAËLE. Brit. 297,331, Sept. 17, 1927. Compds. of azo dyes contg. metals such as Cr, Cu, Fe, Mn, Ni, Co, V, U, Ti, Sn or Al (in which mols. of the same or of different dyes are united by the metal) are prepd. by treating a metal compd. of one of the azo dyes with the same or a different azo dye capable of fixing metal or by treating a mixt. of different azo dyes with metallizing agents. Several examples are given of dyes suitable for use on wool, silk, leather or cotton or for coloring varnishes.

Soluble metal compounds of monoazo dyes. I. G. FARBENIND. A.-G. Brit. 296,819, May 20, 1927. Azo dyes contg. an alkoxy group in *o*-position to the azo group are treated with metal compds. such as Cr formate under conditions suitable for splitting off of the alkyl group, as by boiling under pressure or prolonged boiling under reflux. Products are obtained in better yield than when the usual process of prepg. the *o*-hydroxyazo dye and treating it with metal compd. is employed. Several examples are given.

Chromium compounds of azo dyes. SOC. ANON. POUR L'IND. CHIM. À BAËLE. Brit. 295,504, Aug. 13, 1927. Azo dyes are converted into Cr compds. by treatment in the presence of an alk. reducing agent, with hydrated Cr oxide, with or without pressure, and in some cases in the presence also of a protective colloid or inorg. salt. Numerous details and examples are given. Cf. C. A. 23, 2042.

Azo dyes containing chromium. SOCIÉTÉ ANON. POUR L'IND. CHIM. À BAËLE. Brit. 296,680, Sept. 3, 1927. Chromable azo dyes are baked with reagents yielding Cr such as Cr acetate or fluoride (suitably for 24 hrs. at 145–160°) in the presence of glycerol or of salts such as NaCl, KCl, NH₄Cl, (NH₄)₂SO₄ or of acid-binding salts. Examples are given of the production of dyes which may be used for dyeing cotton, wool, silk, weighted silk, artificial silk or for coloring varnishes. Cf. C. A. 23, 2301.

Dyes containing chromium. SOC. ANON. POUR L'IND. CHIM. À BAËLE. Brit. 296,310, Aug. 27, 1927. Cr-contg. dyes obtained by chroming dyes derived from triaryl-methanes are used to produce dyeings fast to washing, alkali and water on animal fibers, particularly silk and leather, and are also used together with azo dyes contg. Cr to produce dyeings fast to light on the same materials (either in a single bath or in successive baths). Several examples are given.

Dye pastes. E. I. du PONT DE NEMOURS AND Co. Fr. 647,954, Jan. 30, 1928. See U. S. 1,705,818 (C. A. 23, 2305).

Dyes and intermediates. I. G. FARBENIND. A. G. Brit. 296,761, Sept. 7, 1927. Thiophene-2,3-dicarboxylic acid or its anhydride and substitution derivs. are condensed with phenols having 2 unsubstituted adjacent atoms by use of an acid condensing agent; e. g., benzohydroquinone is condensed with thionaphthene-2,3-dicarboxylic acid anhydride or 5-chloro-7-methylthionaphthene-2,3-dicarboxylic acid anhydride and hydroxy-benzohydroquinone with thionaphthene-2,3-dicarboxylic acid anhydride. Thionaphthene-2,3-dicarboxylic acids of the naphthalene and anthracene series are also mentioned as suitable starting materials. The products are hydroxylated 2,3-phthalylthionaphthenes. AlCl₃ with or without NaCl and FeCl₃ may be used as condensing agent.

Dye intermediates. I. G. FARBENIND. A.-G. Brit. 297,129, May 12, 1927. Cinnamylideneanthrone or its derivs. are obtained by heating anthrone or its derivs. with cinnamic aldehyde or its addn. products such as the bisulfite compd., with or without an acid condensing agent such as H₂SO₄, ZnCl₂ or POCl₃. Examples are given of the condensation of cinnamic aldehyde with anthrone, α -hydroxyanthrone and β -chloroanthrone. Benzanthrone or its derivs. are made by heating the cinnamylideneanthrones

with AlCl_3 . *Bz*-1-Phenylbenzanthrone or its derivs. are made by heating the cinnamylideneanthrones to about 250–300° alone or in suspension or soln. as in fused KHSO_4 or a mixt. of NaOAc and KOAc . *Bz*-2-Phenylbenzanthrone or its derivs. are obtained by isomerizing the *Bz*-1-phenylbenzanthrones by heating with AlCl_3 and NaCl . α -Hydroxyanthrone is made by reduction of α -hydroxyanthraquinone by use of Cu and Al and H_2SO_4 . β -Chloroanthrone is prepd. similarly from β -chloroanthraquinone.

Dye intermediates. BRITISH DYESTUFFS CORP., LTD., J. B. PAYMAN and E. G. BAINBRIDGE. Brit. 296,458, May 2, 1927. 1,8-Naphthasultonesulfonic acids are converted, by the action of P halides, into the sulfonyl halides, and the latter are treated with NH_3 or with a primary amine, with substantial exclusion of water, to produce 1,8-naphthasultonesulfonamides, which may be further treated with alkalis to give 1-naphthol-8-sulfonic acid sulfonamides or with NH_3 soln. to give di- or poly-sulfonamide derivs. of α -naphthol. Examples are given.

Anthraquinone condensation products. I. G. FARBENIND. A.-G. Fr. 647,254, June 21, 1927. Anthrone or its derivs. or substitution products is condensed with glyoxal or its higher homologs, or bisulfite compds. or sulfuric esters or other compds. yielding dialdehydes. The reaction is carried out in a solvent and if necessary with the addn. of an acid or a salt with an acid reaction. The products are *intermediates for dyes* and also *dye cotton* from the vat. In examples, glyoxal sulfate is added to a boiling soln. of anthrone in AcOH , giving a product which dyes cotton a clear yellow. With α -chloroanthrone a deep green is obtained.

Dyeing. I. G. FARBENIND. A.-G. (Wilhelm Neugebauer, inventor). Ger. 471,731, May 5, 1926. Goods are dyed by adding to the usual vat dye, the oxidation products of 1,3-dihydroxynaphthalene or its derivs. Thus, the product obtained by the oxidation of 1,3-dihydroxy-2-phenylnaphthalene by FeCl_3 is added to Turkey red oil and water. Soda lye and hyposulfite powder are added and the mixt. is diluted. The goods to be dyed are then immersed. Cotton is dyed a fast brown color by this process.

Dyeing. CHEM. FABRIK A. SCHMITZ. Ger. 471,788, Jan. 31, 1926. Colors fast to rubbing are dyed on materials made from animal or vegetable fibers by treating them with alkali stannate, aluminate or silicate, or with Al acetate, formate, lactate, tartrate or sulfate, before dyeing them in the usual way in an acid-free bath. Albuminous substance such as casein, and alkali or NH_4 borate, and an NH_4 salt of an inorg. or an org. acid are added to the dye liquor.

Dyeing by the aniline black and similar processes. MANCHESTER OXIDE CO., LTD., R. H. CLAYTON and F. SCHOLFIELD. Brit. 296,530, Aug. 4, 1927. Carbonyl-ferrocyanides of the alkali and alk. earth metals are used as O -carriers in dyeing and printing processes involving oxidation. Examples are given of the use of Na carbonyl-ferrocyanide in an aniline black process and in a process for chlorate discharge of indigo. Reference is also made to the discharge of S colors.

Apparatus (with a submerged burner for heating and effecting circulation of the liquid) for dyeing or washing textile materials, etc. C. F. HAMMOND and W. SHACKLETON. Brit. 296,525, April 13, 1927. The supply of fuel and air to the burner may be controlled by a thermostat or by the pressure in the bath.

Dyeing silk. I. G. FARBENIND. A.-G. Fr. 33,576, May 5, 1927. Addn. to 612,169. See Brit. 271,089 (*C. A.* 22, 1693).

Dyeing artificial silk. I. G. FARBENIND. A.-G. Fr. 648,068, Feb. 1, 1928. Artificial silk is dyed by means of azo dyes contg. at most one sulfonic or carboxylic acid group obtained by coupling the diazo compds. of aromatic amines and their substitution products with compds. contg. a heterocyclic ring of 5 members condensed with a benzene ring and having a H atom which reacts easily with diazo compds. Thus, 4-sulfoanilineazomethylketol gives a pure yellow, fast to light on acetate silk; 2,5-dichloroanilineazomethylketol gives clear yellow shades; 2-sulfoanilineazo-3-hydroxythionaphthene gives a deep orange; and 6-chloro-2-aminotolueneazoöxindole gives clear yellow shades tending toward the green.

Dyeing materials of regenerated cellulose. BRITISH DYESTUFFS CORP., LTD., J. BADDLEY, R. BRIGHTMAN and P. CHORLEY. Brit. 296,485, June 7, 1927. Level shades are produced by use of disazo dyes derived from tetraazotized 2,4,4'-diaminodiphenyls (excluding 2,2'-dinitrobenzidine) and 2-mol. proportions of a single or of 2 different coupling components. Several examples are given of products dyeing in various shades. Cf. *C. A.* 22, 3636.

Dyeing and bleaching cellulose esters and ethers. SOC. POUR LA FABRIKATION DE LA SOIE "RHODIASÉTA." Brit. 297,186, July 26, 1927. Material such as that comprising cellulose acetate, after dyeing, is discharged wholly or partially by treatment with substances such as animal charcoal having high adsorbing properties, with or without

addn. of swelling agents and suitably in the form of pastes contg. thickening agents. Several examples are given.

Dyeing fabrics containing both wool and silk. I. G. FARBENIND. A.-G. Brit. 297,124, Sept. 16, 1927. Wool fabrics contg. effects of silk are dyed with wool dyes with the addition of an org. sulfonic acid capable of pptg. gelatin and glue from acid solns. (suitably sulfonated condensation products from phenols and $C_{10}H_8$ and CH_2O —which may be added to the dye bath after the dyeing is complete, or before after-chroming if chromable dyes are used). Examples are given in which the wool is dyed while the silk remains pure white. Cf. C. A. 22, 1243.

Dyeing yarn on perforated beams. JOHN H. HOLTON. U. S. 1,708,417, April 9. Mech. features.

Dyeing animal fibers. BERNHARD SCHÖNER and PAUL VIRCK (to Grasselli Dye-stuff Corp.). U. S. 1,708,635, April 9. Animal fibers such as wool are treated with sulfonated derivs. of naphthylamines such as 4'-aminosulfo-phenyl-2-naphthylamine, 1,4-di(6-sulfo-2-naphthylamino)benzene, 4- α - (or β -) naphthyl-amino-4'-aminodiphenylamine-2'-sulfonic acid, the Na salt of 4- β -naphthylamino-4'-hydroxydiphenylamine-2-sulfonic acid, the Na salt of 1,4-di(4- β (or α)-naphthylamine-2-sulfo-phenylamino)benzene, 1,5-di(4-paramethylphenylamino-3-sulfo-phenylamino)naphthalene or 2,6-di(4-amino-2-sulfo-phenylamino)naphthalene and then treated with an oxidizing agent such as $K_2Cr_2O_7$ and H_2SO_4 . Generally, dark green or black dyeings are produced.

Dyeing apparatus. BRATÍ JOKLOVE. Fr. 647,659, Jan. 24, 1928. Constructional details.

Dyeing apparatus. FRANTISEK RUDOLF. Fr. 647,594, Jan. 23, 1928. An app. is described for dyeing cloth on the full width and in the piece.

Apparatus for dyeing textile materials wound on bobbins mounted in columns in vats. J. ANNICQ. Brit. 296,603, Dec. 5, 1927.

Apparatus (with a vat containing upper and lower sets of rollers) for washing, dyeing, mordanting or other treatments of lengths of cloth. F. RUDOLF. Brit. 296,621, Jan. 18, 1928.

Apparatus for dyeing hats. VELOUR UND FILZHUTFABRIK SINDERMAN & Co. Ger. 472,188, July 5, 1927. See Austrian 108,691 (C. A. 23, 994).

Apparatus for printing cloth simultaneously with several colors. JEAN DUFOUR. Fr. 647,234, June 8, 1927.

Producing colored designs on textiles. I. G. FARBENIND. A.-G. (Kuno Franz and Ehrhart Franz, inventors). Ger. 472,474, Jan. 31, 1926. Textiles are treated with substances convertible into dyes, or with dyes having little affinity for the fibers, while unevenly applying moisture and (or) heat. It is then found that the intermediate or dye distributes itself unevenly over the textile, deeper shades resulting at wetter and warmer parts than at drier and colder parts. Regular or irregular designs can be so produced and the effects can be varied by using stencils, etc., or more than 1 dye. In treating wool or other animal fibers, it is generally necessary first to reduce the affinity of the fibers for dyes, e. g., by bringing on to the fibers cellulose esters or ethers, or starch. Examples are given.

Color printing cloth. JAMES MORTON. Fr. 848,013, Jan. 31, 1928. Fabrics are woven with a pattern by a jacquard or like selecting mechanism and are then printed to produce a colored pattern by rollers or blocks which apply the color but do not form a design, the yarns or threads having been treated so that the ground or other part obscures or changes the colors applied.

Textile threads. JEAN BOVEUX. Fr. 647,177, June 3, 1927. The compn. of linseed oil and beeswax used for treating textile threads to prevent unraveling during weaving, etc., is more easily removed by adding a small quantity of Na or NH_4 sulforinate to the compn. before use. Cf. C. A. 23, 2306.

"Lenosation" of fibers. CHARLES L. FIEVET. Fr. 647,521, Jan. 20, 1928. Vegetable fibers are treated to produce lenosation in a 1% Na_2CO_3 soln., then to an alk. soln. of a vegetable oil solubilized in "tetrapol," then to the action of a 35° Bé. soda soln. contg. monopol soap. The fibers are neutralized, bleached and dried by SO_3 , SO_2 and warm air.

Treating cloth. THE KOPPERS Co. Fr. 647,949, Jan. 30, 1928. See Can. 285,372 (C. A. 23, 719).

Surface treatment of cloth. GEORGES R. J. MOHA. Fr. 647,447, Jan. 18, 1928. The appearance of silk or of gold or silver is given to cotton, etc., by applying a layer of rubber soln. and then a powd. metal such as Au, Ag or bronze.

Obtaining fibers from flax and other materials. ABBEY SYNDICATE, LTD., and D. R. NANJÍ. Brit. 296,333, April 29, 1927. Materials such as flax, hemp, sisal, ramie

and bamboo are treated with a 0.1–0.5% soln. of a neutral salt of one of the alkali metals or of NH_4 (preferably neutral tartrates, citrates, oxalates, sulfates and phosphates which ppt. the alk. earth metals with which the pectinous substances are assocd.), e. g., ramie ribbons in fresh condition may be treated with 0.1–0.5% $(\text{NH}_4)_2\text{SO}_4$ soln. under 1–2 atm. pressure for 60–20 mins., and, after removal of the pectinous complexes, heated in an autoclave with a 2–4% soda soln. under 6–10 atm. pressure for 20–60 mins. to remove fats, waxes, resins, etc. The product may then be bleached. Brit. 396,334 also relates cooking of either the raw or spun or woven material with alk. solns. under pressure to produce a lustrous finish.

Retting flax by use of yeast. MARTIN WADDELL and HENRY C. WATSON (to Watson-Waddell Ltd.). U. S. 1,708,812, April 9. Alc. may be obtained as a by-product.

Artificial fibers. ERSTE BÖHMISCHE KUNSTSEIDEFABRIK A.-G. Fr. 33,612, May 27, 1927. See Brit. 282,687 (C. A. 22, 3778).

Desulfurizing, decoppering and other treatments of artificial fibers. H. RATHERT (to Herminghaus & Co. Ges.). Brit. 297,000, Sept. 10, 1927. The treating liquid is sprayed on to bobbins on which the fiber is wound in twisted condition. Various mech. details are described.

Handling cakes of artificial thread. I. G. FARBENIND. A.-G. Brit. 297,112, Sept. 15, 1927. Mech. features.

Treating cakes of artificial silk manufactured by the can spinning-method. HUGO KÜTTNER (to the Firm Fr. Küttner A.-G.). U. S. 1,708,583, April 9. The cakes are pressed flat and then rinsed and subjected to any further treatment.

Artificial silk. HENRY A. GARDNER. Fr. 647,013, Jan. 12, 1928. See U. S. 1,692,372 (C. A. 23, 719).

Artificial silk. SOC. POUR LA FABRICATION DE LA SOIE "RHODIASETA." Fr. 647,865, Jan. 11, 1928. Cloth or threads of cellulose esters or ethers, such as cellulose acetate, are decolorized totally or in parts by means of highly adsorbent agents such as animal black. The adsorbent may be applied as a paste which may contain swelling agents.

Artificial silk. H. ELLING (to Herminghaus & Co. Ges.). Brit. 297,063, Sept. 13, 1927. Artificial threads prepd. from cellulose derivs. are, in the case of "viscose silk" desulfurized, and in the case of "cuprammonium silk" decoppered, and then bleached, acidified, washed and dyed while wound in the twisted condition on porous bobbins or on perforated bobbins with a porous covering. An app. is described.

Textile lubricant containing an alkali metal lactate. JOSEPH J. SCHAEFER, JR. (to Niocet Chemical Corp.). U. S. reissue 17,264, April 9. See original pat. No. 1,677,852 (C. A. 22, 3306).

Apparatus for applying edge-binding or other coating materials to opposite sides of cloth or similar materials. MARK HAMBURGER and CLAUD H. FOGLE (Fogle to Hamburger). U. S. 1,707,611, April 2.

Waterproofing artificial silk, etc. C. DREYFUS (to British Celanese, Ltd.). Brit. 296,450, Sept. 2, 1927. Open-mesh fabrics such as those made from cellulose acetate are treated with a waterproofing compn. such as a rubber soln. which fills the interstices of the fabric and produces a smooth coating. Fabrics comprising various cellulose esters and ethers may be similarly treated.

Waterproofing embossed fabrics comprising cellulose esters or ethers. C. DREYFUS and W. R. BLUME (to British Celanese, Ltd.). Brit. 296,451, Sept. 2, 1927. Embossed fabrics comprising various cellulose esters or ethers, which may be prepd. as described in Brit. 273,406 (C. A. 22, 2068), are treated with a waterproofing material such as a rubber soln., which is preferably applied by spraying to the under side of the embossed material.

Bleaching. OTTO FLEISCH. Ger. 471,877, May 21, 1927. Textile goods, especially wool, are bleached by gaseous H_2SO_3 in a canal-like chamber of which the inlet and outlet for the goods are permanently open. The gas is blown in by app. so arranged that it sucks in air and does not escape from the bleaching chamber.

Laundering textile fabrics. ROBERT A. PHAIR (to H. Kohnstamm & Co.). U. S. 1,708,519, April 9. Fabrics such as cotton are washed in a usual manner and then rinsed in water to which is added a protective agent such as CaCO_3 or $\text{Mg}(\text{OH})_2$, which remains in the goods and serves to prevent destructive action of acid vapors and formation of destructive acids in the fabric.

Machine for washing several hanks of yarn simultaneously. MASCHINENFABRIK UND EISENGIESSEREI WILHELM QUADE G. M. B. H. Ger. 471,621, Dec. 10, 1926. Details of construction.

26—PAINTS, VARNISHES AND RESINS

A. H. SABIN

Luminous paints. OTAKAR WEBER. *Chem. Listy* 23, 59-60(1929).—A review showing that the color is evolved in 2 phases: (1) an intense light of great brilliance lasting a few mins., (2) a mild glow which usually remains overnight and lacks intensity and depth. The intensity cannot be increased by applying a thicker layer of the paint.

The present state of the lead paint question. K. WÜGGH. *Korrosion Metall-schutz* 5, 14-8(1929).—The development of uses of mixed lead pigments in paints is reviewed with reference to toxicity and discoloration on exposure. B. E. R.

Experience with fume paints (smoke-proof paints). W. VAN WULLEN-SCHOLTEN. *Farben-Ztg.* 34, 1061 3(1929).—Paints prepd. with white lead and lamp black ground in a linseed-oil varnish on the one hand and in a tung-oil, stand-oil varnish on the other were spread on bare iron panels and also on panels which had been primed with red-lead paint. These panels were placed in a smoke stack and subjected to the fumes therein. The linseed-oil paints showed better durability. G. G. SWARD

A new method of observing the progress of drying. HANS WOLFF AND W. TORLDT. *Farben-Ztg.* 34, 1060 1(1929).—A 2% soln. of brilliant scarlet in linseed oil is spotted at suitable intervals onto the film being tested. As drying proceeds the successive drops spread to a decreasing extent, which passes through a min. at the dust-free stage. G. G. SWARD

Oxidation and polymerization of sunflower oil. G. NEMIROVSKII. *Oil and Fat Industry* (Russia) 1928, No. 4, 23 6. The formation of hydroxy acids as well as the increase in sp. gr. and viscosity depends on the amount of air used in the blowing process, on the temp. and on the catalysts present, such as Mn and Pb acetates and linoleates of Mn, Pb and Co. Mn salts have less influence on the formation of hydroxy acids and the increase in sp. gr. than Pb salts. A temp. increase during the reaction with the above salts has less influence on the speed of reaction than the duration of contact, particularly for Mn acetate. Co linoleate gives a higher yield in hydroxy acids than the other catalysts. A. A. BOEHTLINGK

Contributions to forensic chemistry. TIMM. Univ. Leipzig. *Deut. Z. ges. gericht. Med.* 11, 185 8(1928).—On autopsy Pb was found in the kidney (4.47 mg. per 150 g. of tissue) and blood (1.33 mg. per 150 g.) of a man employed for 20 yrs. in a lacquer factory. FRANCES KRASNOW

Bitumen as a protection against corrosion in the chemical industry. A. W. RICK. *Chem. Fabrik* 1929, 100-1.—Far better than oil paints, tar paints, crude asphalts and petroleum pitch as protectives against corrosion of materials are specially prepd. bituminous lacquers and thicker solns. of bitumen or bituminous compns. These give the necessary impenetrability, toughness, resistance to attacks by chemicals, etc. Instances are cited. W. C. EBAUGH

A new color reaction for resin. M. MAMONT. *Ind. olii min. e grassi* 9, 43-4 (1929).—Place a mixt. of 0.2-1 g. of the dry substance and CaO in a glass test tube of 5-10 mm. diam., warm slowly on a direct flame and pass the vapors over a few drops of HNO₃, d. 1.40. With resin a violet red color results. The condensation products form drops on the acid first violet, then green and blue. With soaps the reaction is sensitive with 1-2% of resin. Waxes, excepting shellac, do not give the reaction. Autoxidized resin does. R. SANSONE

The principles of synthetic resin formation. JOHANNES SCHEIBER. *Farbe u. Lack* 1929, 86-9, 102-3.—The resinous state is usually one of supercooled or solid soln. & briefly reviews the factors which promote crvstn. as developed by Tamman, Haber, and von Veimarn. The principal groups involved in the formation of resins are $-\text{CH}=\text{CH}-$, $-\text{C}=\text{O}$, $-\text{C}=\text{NH}$, etc. The polymerization factor of unsatd. compds. varies with the groups attached to the doubly bound C atoms. The desirable properties, such as chem. resistance, elec. resistance, soly., etc., are sometimes more easily attained with synthetic compds. than with the natural ones. Shellac, being a mixed animal and vegetable resin, has properties more difficult to reproduce. G. G. SWARD

The reason for the low melting point of rosin extracted from wood stumps. E. LYUBARSKII. *Oil and Fat Industry* (Russia) 1928, No. 4, 26-30.—Heavy ends of turpentine are left in the stump shavings on distg. off turpentine; they contaminate the rosin obtained by the extn. process. A small part of the org. solvent is also left in the rosin on distn. The remedy suggested is to distill off the light compds. from the stump

shavings, saponify the rosin in the presence of shavings, boil the soap soln. until all heavy oils are evapd. and sep. from dirt, etc. The rosin soap can be converted to rosin by the usual methods, or left as such to be used in the soap industry. A. A. B.

Consistency and gel formation (WAGNER) 2. The durability of colors for painting on glass (GREINER) 19. Condensation products of indene with phenols [for bases for lacquers] (Brit. pat. 297,075) 18. Condensation products of urea or its derivatives and CH_2O (Brit. pat. 296,361) 18. Glaze [from urea-formol resin products] (Brit. pat. 647,834) 19. Plastic composition, lacquers, etc., containing cellulose esters or ethers (Brit. pat. 296,796) 18. Azo dyes containing Cr [for coloring varnishes] (Brit. pat. 296,680) 25.

Bakelite Technic. Molding Materials. New York and Chicago: Bakelite Corp. 104 pp.

SCHEIBER, JOHANNES, AND SÄNDIG, KURT: *Die künstlichen Harze. Band XIV of Chemie Einzeldarstellungen.* Stuttgart: Wissenschaftliche Verlagsgesellschaft m. b. H. 376 pp. M. 26; bound, M. 28.

Device for mixing constituents of paints in cans. HENRY C. KIESELBACH. U. S. 1,707,968, April 2.

Iron oxide pigment. F. RIVERS. Brit. 296,598, Nov. 17, 1927. A material suitable for use in paints is prep'd. by burning a clay contg. not less than 25% Fe oxide and crushing the burned product. Various details are described.

White lead. T. GOLDSCHMIDT A.-G. Brit. 297,116, Sept. 15, 1927. In producing colloidal white lead by the treatment of Pb oxide with CO_2 in the presence of water, an accelerator is used such as NH_3 which is of a neutral or alk. character and has no appreciable solvent action on the Pb oxide but assists in its conversion to carbonate.

Oil paints and varnishes. I. G. FARBENIND. A.-G. Brit. 296,679, Sept. 2, 1927. Oil paints and varnishes such as those comprising linseed oil have added to them an aliphatic carboxylic acid unsat'd. in the α - β or β - γ position or derivs. such as acrylic acid or its polymerization products, crotonic acid or sorbic acid, which give good covering and brushing properties to the paints or varnishes and enable larger quantities than usual of pigments to be added.

Oil paints and varnishes. I. G. FARBENIND. A.-G. Brit. 296,991, Sept. 10, 1927. Hydroxy acids such as glycolic, phenoxyacetic or cresoxyacetic acids are used in small proportions in oil paints and varnishes such as those formed with polymerized linseed oil, driers, thinners and pigments. Brit. 296,902 specifies the similar use of amides such as hydroxymethylbenzamide, butyl urethan, hydroxymethylbutyl urethan or ethylglycol urethan.

Oil paints and varnishes. I. G. FARBENIND. A.-G. Brit. 297,034, Sept. 12, 1927. Paints or varnishes such as those formed with linseed oil also contain an aromatic hydroxy carboxylic acid or deriv., e. g., a small proportion of β -hydroxynaphthoic acid. A lacquer may be formed with addn. of drier, thinner and zinc white.

Fireproofing material for use with paints. FERNANDO S. VIVAS (to International Fireproof Products Corp.). U. S. 1,707,587, April 2. An aq. soln. is formed from H_3BO_3 , borax, ZnSO_4 and Na tungstate and this soln. is combined with a soln. of gelatin and a paint filler such as "asbestine pulp" and TiO_2 is added to form a paste which is further mixed with a "fireproof drying oil" such as an oil mixed with borax, NH_4Cl , H_3BO_3 and Na tungstate to form a paint. Cl. C. A. 23, 908.

Oxidizing drying oils. I. G. FARBENIND. A.-G. Ger. 472,111, Aug. 12, 1927. Drying oils are treated with air or O while suspended in a liquid in which they are insol. e. g., in water, aq. solns. of org. acids, alcohols, etc. Colloids, e. g., gelatin, may be added to prevent coagulation of the oxidized oil, and accelerators, e. g., comp'd. of Pb, Mn or Co, may be present also. Examples are given.

Varnish. SOC. DES VERNIS TAB. Fr. 647,161, June 2, 1927. Casein is made sol in alc. for use in varnishes by swelling it with water or alc., adding either (1) substs. which act on the acid groups of the casein such as alkalis, carbonates, bicarbonates, phosphates, lime or org. amines, (2) substances which act on the amino groups of the casein such as oxalic, phosphoric, citric, benzoic, acetic or phthalic acids, or (3) substances whose action is difficult to define such as sulfates, chlorides, oxalates, fluo. phenol or thymol, mixing and heating till a homogeneous paste is obtained and then adding the required amt. of alc.

Varnish. THEODOR SCHUCHARDT G. M. B. H. Ger. 471,725, June 29, 1927.

non-cracking varnish coating with a nitrocellulose foundation is obtained by adding resin, resin esters or oil to the layer painted over the colored layer.

Varnishes containing synthetic and natural resins and organic cellulose derivatives. W. H. MOSS and C. DREYFUS. Brit. 296,675, Sept. 3, 1927. Cellulose derivs. such as cellulose acetate, formate, propionate and butyrate or methyl or ethyl cellulose ethers are used with either synthetic resins such as those formed from a phenol and aldehyde or with natural resins such as dammer, kauri, manila, sandarac, copals, ester gums, plasticizers, solvents, pigments, etc.

Varnishing. I. G. FARBENIND. A.-G. (Adolf Benischek and Carlos Thode, inventors). Ger. 471,599, Mar. 27, 1927. The article to be varnished is immersed in a boiler filled with varnish which is caused to circulate by a current of warm air.

Polish. JOHANNES FLECKEN. Ger. 471,862, Jan. 18, 1927. A silk-like polish is imparted to varnished goods by treating with a soln. of $(\text{CH}_3)_2\text{CO}$, oil and turpentine, and washing with water.

Cellulose acetate lacquers, etc. I. G. FARBENIND. A.-G. Ger. 472,311, Nov. 27, 1924. Lacquers, impregnating agents, etc., comprising solns. of cellulose acetate in a monochlorhydrin, with or without other solvents, are rendered more stable by addn. of a small amt. of a cyclic org. base, e. g., PbNH_2 , pyridine, or quinoline.

Marking or printing ink. H. PLATT and C. DREYFUS (to British Celanese, Ltd.). Brit. 296,759; Sept. 7, 1927. An ink unaffected by dyeing or bleaching processes consists of a pigment such as vermillion, ultramarine (or, preferably, Pb chromate), a drying or semi-drying oil (suitably linseed oil or china wood oil), and a cellulose deriv. (suitably nitrocellulose dissolved in ether and alc., or, preferably, in EtOAc). The ink is especially suitable for marking cellulose acetate fabrics.

Coloring materials for making India ink, etc. I. G. FARBENIND. A.-G. Brit. 297,076, March 14, 1927. "Soot" or other finely divided coloring materials are prep'd. by grinding with an addn. of sulfonic acids or their salts such as those obtained by sulfonating mineral oils, oil distillates, brown coal-tar oils or similar mixts. contg. aromatic, hydroaromatic and sat'd. or unsat'd. cyclic and aliphatic compds. An example is given of the treatment of "soot" and of the treatment of umber with the Na salt of the sulfonated product obtained from a mixt. of naphthenic acids.

Molding mixture. LEWIS M. HULL (to Radio Frequency Laboratories). U. S. 1,708,576, April 9. A molding mixt. suitable for condenser parts comprises a low hysteresis phenolic resin and a filler such as mica which is substantially non-reactive during the molding process and which does not substantially increase the hysteresis loss in the molded product; the product is characterized by a phase difference not exceeding about 1° .

Purifying resins. HERCULES POWDER CO. Fr. 647,543, Jan. 20, 1928. Resin is heated to a temp. below its f. p. and sufficient to distil all the volatile constituents by causing it to flow on a heated surface below atm. pressure and with the introduction of superheated steam.

Artificial resins. ALLGEMEINE ELEKTRICITÄTS GES. (to International General Electric Co.). Brit. 296,787, Sept. 8, 1927. Artificial resins such as those produced from condensation of glycerol and phthalic acid are obtained in a practically colorless condition by effecting the condensation in an atm. substantially free from O (suitably in H_2 , CO_2 or in a vacuum).

Phenol-acetylene resin. HOWARD W. MATHESON and JULIUS A. NIEUWLAND (to Canadian Electro Products Co.). U. S. 1,707,940, April 2. A condensation product of a phenol such as PhOH with C_2H_2 is treated with C_2H_2 at a temp. above 100° , producing a product substantially free from uncombined phenolic material, and which is rendered infusible and insol. by heat and pressure. U. S. 1,707,941 also relates to the production of synthetic resins by reaction of phenol and C_2H_2 in the presence of a catalyst such as H_2SO_4 and HgSO_4 .

Synthetic (phenol-aldehyde) resins. W. H. MOSS and C. DREYFUS (to British Celanese, Ltd.). Brit. 296,674, Sept. 3, 1927. In the formation of fusible and sol. resins (suitable for use in varnishes together with org. esters of cellulose or cellulose ethers), at least the final stage of the condensation is effected in the presence of a sol. di-H phosphate such as that of an alkali or alk. earth meta. or of NH_4 . The condensation may be initiated in the presence of H_3PO_4 and alk. earth oxide or hydroxide or Na_2CO_3 , subsequently added to form the di-H phosphate. Equi-mol. proportions of a phenol and aldehyde are preferably used, and the products are preferably washed with hot water and steam or subjected to vacuum distn.

27—FATS, FATTY OILS, WAXES AND SOAPS

E. SCHERUBEL

Influence of metal on the quality of glycerol. A. BAG. *Oil and Fat Industry* (Russia) 1928, No. 4, 13-4.—Pure glycerol contg. 0.005% ash and 0.008% H_2SO_4 was heated in a glass flask at 120–125° in the presence of various metals. Al and Cu have the smallest and Fe and Pb the greatest effect on the quality. The glycerol was greatly improved after filtering through paper and blood charcoal. Most of the mineral admixtures could be removed. A. A. BOEHTLINGK

Detection of cacao butter adulteration by means of benzoic peroxide. KURT BODENDORF. Univ. Berlin. *Pharm. Ztg.* 74, 384-5 (1929).—The method involves treatment of the sample with a CHCl_3 soln. of benzoic peroxide, as follows: To a soln. of 2 g. of the sample in 10 cc. of CHCl_3 add 40 cc. of reagent (see below), the content of which has been carefully detd., so that for 5 cc. about 12–13 cc. 0.1 N $\text{Na}_2\text{S}_2\text{O}_3$ will be consumed. The temp. (about 40°) should remain const. during the entire operation by immersion in a water bath. From time to time (the reaction is complete after the lapse of 170 mins.) remove 5 cc. of the CHCl_3 soln. to an acidified KI soln. and after vigorous agitation titrate the pptd. I with 0.1 N $\text{Na}_2\text{S}_2\text{O}_3$. The end point is reached when no further recession in the amt. of pptd. I is observable, at which time there should still be an excess of benzoic peroxide present. Curves constructed on values (based on time of action and benzoic peroxide consumed in terms of $\text{Na}_2\text{S}_2\text{O}_3$) obtained in examn. of pure cacao fat and other fats likely to be used in adulteration show 2 possible groups of fatty admixt.: (1) of fats having greater, and (2) of fats having less unsatn. than cacao butter. The relative position of the curves of samples in question to that of pure cacao butter permits estn. of the extent of adulteration. The paper contains several series of analyses with the corresponding curves. *Prepn. of reagent.* Dissolve 10 g. benzoic peroxide in 100 cc. of $\text{Et}_2\text{O} \cdot \text{CHCl}_3$ mixt. (1:1) and cool to 0°, add an equally cooled soln. of 1 g. Na in 20 cc. of alc. in a thin stream with proper agitation, immerse $\frac{1}{2}$ hr. in ice water, then dissolve the magma in 200 cc. of ice water, sep. the mixt. in a separatory funnel, acidify with dil. H_2SO_4 and ext. the benzoic peroxide with two 150-cc. portions of CHCl_3 . Dry over Na_2SO_4 , filter and adjust by addn. of more CHCl_3 so that 5 cc. is equal to about 12–13 cc. 0.1 N $\text{Na}_2\text{S}_2\text{O}_3$. W. O. E.

Fat splitting and neutral fat saponification. K. MÜLLER. *Seifensieder Ztg.* 56, 67-8 (1929); cf. C. A. 22, 4851.—M. discusses the variations of glycerol content in lye due to different kettle charge conditions, basing his views on F. Merklen's investigations as published in his book on settled soaps. P. ESCHER

Preparations resembling Turkey red oil in soaps. J. AUGUSTIN. Munich. *Seifensieder Ztg.* 56, 69-71 (1929).—"Cimol-Neutral," a prepn. resembling Turkey red oil (compn. not given), was added to soaps, and results are tabulated for free alkali, lathering power and emulsifying power to show its beneficial effects. P. ESCHER

Olein analysis. M. KELLER. *Seifensieder Ztg.* 56, 57-8 (1929). Answer to Dittmer's criticism (C. A. 22, 2476, 4845, 23, 1005). P. ESCHER

Determination of the saponification value of fatty oils. THEODOR BOEHM AND PHILIPP FRESNIER. Univ. Berlin. *Apoth. Ztg.* 44, 349-51 (1929). The results obtained in the present study indicate that a preliminary series of tests is superfluous to det. the action range of alc. KOH; it is entirely sufficient if the factor of alc. KOH is detd. in the usual way in the subsequent examn. It is important that the sapon be carried out in a 200-cc. Jena glass (with mark). The procedure followed is: Weigh 1 to 2 g. of the sample into a 200-cc. Jena flask, add 25 cc. alc. KOH, close with a cork carrying a 75-cm. long cooling tube, then heat the mixt. about $\frac{1}{2}$ hr. on the water bath, agitating the liquid from time to time but avoiding contact with both stopper and tube. In the clear hot soln. titrate the KOH excess with 0.5 N HCl in the presence of phenolphthalein. W. O. E.

Polymerization of the highly unsaturated acids. I. YOSHIYUKI TOYAMA AND TOMOTARO TSUCHIYA. Tokyo Imp. Inst. Chem. Tech. *Chem. Umschau Fette, Oele, Wachse Harze* 36, 45-9 (1929).—See C. A. 23, 1873. P. ESCHER

Hydrogenation of the highly unsaturated acids. II. Hydrogenation of their methyl esters with platinum black. YOSHIYUKI TOYAMA AND TOMOTARO TSUCHIYA. *Chem. Umschau Fette, Oele, Wachse Harze* 36, 49-52 (1929).—The methyl esters of the highly unsatd. acids of a Japanese sardine oil (cf. above abstr.) were dissolved in alc. and hydrogenated at room temp. and atm. pressure with $3\frac{1}{4}\%$ Pt black by shaking, and samples of the product were taken at intervals. The acids of the Me esters were composed of $\text{C}_{20}\text{H}_{38}\text{O}_2$, $\text{C}_{20}\text{H}_{36}\text{O}_2$, $\text{C}_{20}\text{H}_{34}\text{O}_2$ and $\text{C}_{22}\text{H}_{36}\text{O}_2$; they yielded 133.2% ether-insol.

bromides of 71.22% Br content, and 170.9% of petroleum-ether-insol. bromides of 66.81% Br content. When the original I no. of 354.8 had fallen to about 170 during hardening, the product was semi-solid and the sepd. 40% solid acids had an I no. of 55 and m. p. of 73°. The yield of the insol. bromides fell with increasing hydrogenation and at I no. 119.9 their yields were only 3.24% ether-insol. and 25.83% petroleum-ether-insol. bromides. From their yields and Br content it is concluded that at best only a small quantity of the acids $C_nH_{2n-6}O_2$ and $C_nH_{2n-5}O_2$ are present during hydrogenation, although they could be formed from the more unsatd. acids. These solid acids formed from the very start of hydrogenation and thus the Pt catalyst differs from the Ni catalyst, which latter sats. all of the more unsatd. acids to the oleic acid stage before any solid acids are formed. There were also found some solid acids of the $C_nH_{2n-4}O_2$ group which showed a higher m. p. than the naturally occurring C_{20} and C_{22} members of that group. All results are detailed in tables. P. ESCHER

Regulations in the edible-oil industry. MARIO S. PENTEADO. *Chimica industria* 3, 498-503(1928).—After a brief general consideration of the constitution and properties of fats and oils, P. considers that drying oils become rancid largely as a result of the suspended org. detritus present serving as residence for hydrolytic enzymes. Density, fusion pt., solidification pt., acidity, index of refraction, butyrefractive index, sapon. no., iodine no., Hehner no. and Reichert-Meissl no., are briefly considered and a table of values is given for 7 oils. It was common to sophisticate butter with water sometimes up to 79%. Some regulations are quoted, among which are: (1) It should contain not over 18% moisture and not less than 80% milk matter. (2) It should be kept below 15° and 100 g. should not show a greater acidity than 8 cc. N alkali. (3) Butter to which salt has been added but otherwise prepd. according to regulations previously stated should be labeled butter preserved by salt. (4) Such butter should have acidity not over 15 cc alkali. (5) Vegetable colorants may be added. (6) All other preservatives are prohibited except salt, which may not exceed 10%. (7) Butter which has been revived shall be called renovated butter and its acidity shall not exceed 25 cc. N alkali. (8) Edible fats simulating cow butter shall not be exposed for sale under the name of butter. (9) Margarine and the like shall neither be made, deposited, nor sold in dairies. (10) Mixts. of vegetable fats plus a max. of 10% butter shall be termed margarine. (11) Fatty substitutes may be sold under the term vegetable butter but the origin must be indicated. S. L. B. ETHERTON

Oil from grape kernels. N. KOZIN. *Oil and Fat Industry* (Russia) 1928, No. 8, 24-6.—Kernels from white muscat grapes from Nikitskii Botanical Garden (Crimea) from 1926 crop had the following compn.: Moisture 8.59, fat 13.58, crude protein 11.08, epidermis 35.25 and ash 2.92%. The oil obtained by cold pressing was of a greenish yellow color changing into golden yellow after standing; it had a raisin-like odor and agreeable taste. Its characteristics are: d_{15}^4 0.9220, n_{40}^D 1.4678, acid no. 3.33, sapon. no. 192.57, I no. 131.24, unsapon. matter 0.92%, drying at 21° in 114 hrs.; the O no. of oil boiled with water is 14.1%, not treated with water 14.4%. The Russian grape kernels are lower in oil than Italian. It can be used for edible purposes and has a taste similar to that of olive oil. It is easily sol. in glacial acetic acid at 70° and becomes turbid at 60.5°, is only partly sol. in 95° alc.; its drying qualities are inferior. Hot-pressed kernels give a dark oil of disagreeable taste. A. A. BOEHLINGK

The "Wecker" method. "KRONOS." *Seifensieder Ztg.* 56, 63-4(1929).—Critical discussion of Keutgen's article on oil neutralization and fatty acid distn. (C. A. 23, 2052). P. ESCHER

Extraction of orujos with carbon disulfide. J. BOHLE. *Chem.-Ztg.* 53, 165-7, 187-9(1929).—Orujo is the press cake of olive-oil mills, contg. 6-15% oil with an av. of 10-12%. The cake is coarsely ground, dried in drum driers to 15-16% H_2O and these are extd. with CS_2 , furnishing the "sulfur oil" of the trade, which contains 4-50% free fatty acids. By using trichloroethylene in place of CS_2 , a non-bleaching oil results; this fact and economic conditions prevent abandoning the use of the inflammable CS_2 in favor of the safe C_2HCl_3 . Details of construction and operations are given. An unsolved problem of this industry is the prevention of fermentation processes in the rapidly accumulating masses of cakes in the early weeks of the harvest. P. ESCHER

Solubility tests of castor oil. H. P. TREVITHICK and M. F. LAURO. *Oil and Fat Ind.* 6, No. 3, 27-9(1929).—Failure to pass the soly. tests for castor oil, especially those specifying alc. of less than 95% strength, should not be considered as proof of adulteration. While all authors state that the filtration and distn. methods of detg. the acetic acid liberated from acetylated oil give the same results, T. and L. were unable to obtain concordant results by the filtration method and propose the following: boil 20 g. of

dry filtered oil with 20 cc. acetic anhydride and 10 g. of anhyd. Na acetate in a round-bottom 150-cc. flask with air-jacketed reflux condenser for 2 hrs. allowing no caking. Cool somewhat and rinse the condenser with 50 to 80 cc. H_2O . Pour the flask contents into 500 cc. H_2O in a beaker and boil 30 min. with glass beads to prevent bumping. Siphon off the H_2O and boil the oily layer with H_2O until no longer acid to litmus. Sep. the acetylated fat from H_2O , filter and dry at 100° . Weigh 2-4 g. of this fat into a 500-cc. Erlenmeyer flask, add 50 cc. alc. KOH (40 g. per l.) and saponify 1 hr. Evap. the alc. and dissolve soap in H_2O , acidulate the soap soln. of the saponid. acetylated fat with H_3PO_4 , using Me orange and distil with steam into an Erlenmeyer flask contg. 40 cc. of 0.25 N NaOH until 400 cc. has passed over. Titrate back with acid and continue to distil until 100 cc. does not require more than 0.1 cc. of the NaOH. The total cc. of NaOH $\times 2.5 \times 5.61 \div$ by wt. of sample = acetyl value. E. S.

Benzine and alcohol as solvents for castor oil. A. SLASHCHIEV. *Mussloboino Zhirovye Delo* 15, No. 7(1928); *Chem. Umschau* 36, 42; *Squibb Abst. Bull.* 2, A-207 (1929); cf. C. A. 22, 2674.—Comparative expts. were performed with regard to the extn. of castor-oil seeds of various grades with benzine, C_6H_6 , EtOH, petroleum ether, etc., with the result that benzine was found to be a very satisfactory extn. solvent; it is comparable in efficacy to C_6H_6 and CS_2 , giving the same yields of castor oil. EtOH extn. produces greater yields (48.16% as compared with 47.58% for benzine) but the resultant oil is not free from foreign matter; with benzine a light castor oil is obtained, while with the other extn. solvents, especially CS_2 , a more or less colored product is the rule. The extn. was performed at $30-55^\circ$, the seeds being totally oil-free at the end of 12 hrs.; by the addn. of 2.5-10% of C_6H_6 to the benzine, the soln. of the seed oil in the latter is considerably enhanced. C. R. F.

Determination of neutral fat in sulfonated oils. RALPH HART. *J. Am. Leather Chem. Assoc.* 24, 120-1(1929).—By detg. the sapon. no. of a sulfonated oil, % neutral oil can be detd. if the sapon. no. of the original oil is known. Alc. soln. of the sulfonated oil must first be neutralized to phenolphthalein. NH_4 soaps, if present, act like free fatty acids toward this indicator. Satisfactory agreement was obtained in comparing this method with the usual sepn. method for neutral oil. H. B. MERRILL

Soaps from organic bases. R. B. TRUSLER. *Soap* 4, No. 7, 33-5(1929); cf. C. A. 23, 2056.—Soaps from hydroxyalkylamines, known as the ethanolamines, when anhyd. depend for their consistency upon the nature of the fatty acid employed. The oleate of mono-ethanolamine is like petroleum jelly, while the oleates of di- and triethanolamine are only slightly more viscid, while the mono-ethanolamine stearate is a hard, wax-like solid. Among the uses of these soaps it has been found that from 0.3 to 1% dissolved in lubricating oils, increases their viscosity so that they are non-running and become suitable for pressure oiling and cup greases. The most important application of the oleate soap is in dry-cleaning, as it remains in soln. in the solvent in the presence of small quantities of H_2O . Ethyl, methyl, and benzylamine form soaps with fatty acids. Ethylenediamine is a double amine which can combine with 1 or 2 fatty acid mols. The mono-oleate and mono-stearate of ethylenediamine are strongly basic in H_2O and froth readily. E. SCHERUBEL

Cold-made toilet soaps. EUGENE SCHUCK. *Am. Perfumer* 23, 772-4; 24, 61 (1929).—This is a discussion of the manuf. of coconut-oil soaps. Because these soaps contain about 15% of unsapond. oil, it is thought that this might explain the tendency toward rancidity which they possess. This unsapond. portion consists of 83% diglyceride and 17% monoglyceride of lauric and oleic acids. The free fatty acids present in the unsapond. oil consist of a low mol. mixt. of capronic and caprylic acids. The unsapond. glycerides do not contain these, which have a peculiar odor and the faculty of rapid oxidation. S. believes that here is a clue to the development of rancidity. E. SCHERUBEL

Alkaline earth stearate emulsions. ALAN P. LEE AND JOHN E. RUTZLER. *Oil and Fat Ind.* 6, No. 3, 15-8(1929).—The peptizing action of these soaps is due to their concn. at the liquid interface and to the subsequent formation of a tough elastic film of particles of the soap around the drops of H_2O . From the character of the soaps dealt with, it appears that the hydrophobic film consists of discrete particles. The variations found in viscosities can be explained upon the assumption that there is a diff. in the H_2O particle size under the diff. conditions. The soly. of the soap in the oil can take but little, if any, part in detg. the character of these emulsions, for the work was done with concns. in excess of the solubilities of the several soaps at the temps. employed. E. SCHERUBEL

Soaps used in the textile industry (Hucams) 25. Emulsified and saponified oils

(SINGER) 22. Overflow alarm device for filtering apparatus (U. S. 1,708,235) 1. Centrifugal apparatus for purifying oils, etc. (Brit. pat. 296,670) 1. Tank and baffle plate construction for separating oil from water by gravity (U. S. pat. 1,708,021) 1.

Vegetable fats. FABBRICA CHIMICA ARENELLA. Fr. 33,640, June 8, 1927. Addn. to 635,628. The yield of fatty substances obtained by the process of Fr. 635,628 (C. A. 22, 4853) from grape skins is increased by a preliminary treatment with steam.

Separation of lipid mixtures. SCHERING-KAHLBAUM A-G. (S. Loewe, inventor). Ger. 466,363, Sept. 11, 1925. Lipoid mixts. of which the components possess differing degrees of dispersion in aq. and org. solvents, are sepd. by using a membrane which allows only the components of higher dispersive power to pass. Thus, a soln. of salicylic and stearic acids in alc. is dialyzed by a colloid membrane with 70% alc. After repeated changes of alc., the stearic acid is found to have left the original soln., which contains only salicylic acid. Other examples are given.

Sulfonated fatty acids. I. G. FARBENIND A-G. Brit. 296,999, Sept. 10, 1927. Acid- and lime-resisting products are obtained by sulfonating unsatd. fatty acids such as oleic acid with fuming sulfuric acid in the presence of halogenated unsatd. hydrocarbon derivs.: e. g., oleic acid is treated with fuming sulfuric acid in the presence of trichloroethylene; or castor oil may be similarly treated. Cf. C. A. 23, 1512.

Sulfonating oils, etc. ERBA A-G. Brit. 296,935, Nov. 22, 1927. The process described in Brit. 294,621 (C. A. 23, 2057) for sulfonating castor oil or similar fatty oils in the presence of bleaching agents is used for the sulfonation of other animal or vegetable oils, fats, fatty acids or waxes which are capable of sulfonation; e. g., polybasic acids such as mucic, adipic or suberic acids and waxes such as Japan wax, beeswax or carnauba wax. The sulfonation may be carried out with org. sulfonic acids such as β -naphthalenesulfonic acid, with or without H_2SO_4 , and the products may be used for treating textile materials and are capable of softening natural or artificial fibers or spun yarns.

Sulfonated oils. H. TH. BOHME A-G. Fr. 647,417, Jan. 17, 1928. Fatty acids or their glycerides are sulfonated with excess H_2SO_4 at a temp. below 0° , if necessary with the addn. of diluents to keep the mass liquid. An example is given of the sulfonation of ricinoleic acid with an equal weight of H_2SO_4 at -10° and in the presence of half the weight of C_6H_6 .

Extraction of oil from livers. ALFRED EHRENREICH. Fr. 647,941, Jan. 30, 1928. An oil is extd. from the livers of plagiostomes, especially sharks, by grinding and pressing or steaming or by org. solvents. It m. -15° and may be used as a food or in pharmacy.

Purifying oils. AKT.-GES. FÜR KOHLENSÄURE IND. and E. B. AUERBACH. Ger. 472,212, Feb. 13, 1927. Addn. to 460,531. Ger. 460,531 describes the purification of mineral oil mixts. or their sepn. into constituents by extr. with liquid CO_2 . This method is now applied to other oils, e. g., fatty, resin, or ethereal oils, or to mixts. of such oils with mineral oils. Examples are given describing (1) the sepn. from an illuminating oil of petroleum and colza oil, and (2) the purification of (a) crude colza oil, (b) crude amber oil, and (c) residues from the manuf. of turpentine.

Moistening cottonseed meats preliminary to extraction. HERMAN C. GRAEBE (to Proctor & Gamble Co.). U. S. 1,707,949, April 2. An app. is described in which the meats are moistened while passing through a continuous feeding device and then are allowed to stand in a closed receptacle for at least 1 hr. before further treatment.

Soap. ERNST FLAMMER and L. C. KELBER. Ger. 472,047, April 12, 1925. Addn. to 428,878. Ger. 428,878 describes the manuf. of flaky products from a mixt. of a soap having 8-14% H_2O with a compd. evolving O , e. g., a perborate. It is now found that these products can be rendered transparent by including in the mixt. a higher hydrocarbon of the CH_4 or C_4H_8 series, or a hydroxy compd. or ester derived from such a hydrocarbon. Examples are given describing the use of cetyl palmitate and gently oxidized paraffin free from acid. Cf. C. A. 22, 508.

Soap. HANS HOFFMÜLLER VON KORNATZKI. Ger. 472,410, Aug. 27, 1925. See U. S. 1,684,336 (C. A. 22, 4266).

Soap. INDUSTRIAL SPRAY-DRYING CORP. Fr. 647,341, Jan. 5, 1928. An app. is described for producing a soap in the form of globular particles of a uniform size by injecting molten soap into a gas heated to about 149° . Cf. C. A. 22, 4854.

Soap cakes with flat fillers of wood, celluloid, paper or other material insoluble in water. ROGERA UNKAMP. U. S. 1,707,334, April 2. Structural features.

28—SUGAR, STARCH AND GUMS

J. K. DALE*

Possible economies in the sugar industry. V. SÁZAVSKÝ. *Listy Cukrovar.* 47, 294-9(1929).—A discussion.

Sugar technology in the year 1928. O. W. WILLCOX. *Facts About Sugar* 24, 230-2, 236(1929).—Recent trends and improvements in the technology of beet and cane sugar are briefly reviewed.

Aid to a sugar chemist. OTTO SCHÄFFER. *Listy Cukrovar.* 47, 315(1929).—S. describes a logarithmic rule which computes the quotient and percentage of sugar from polarization readings and sp. gr. and which eliminates the use of tables.

Does the Petree process pay in Tucumán? W. M. GRAYSON. *Planter & Sugar Mfr.* 81, 381-3(1928); *Intern. Sugar J.* 31, 75-81(1929).—At the present time of low prices and overproduction of sugar in Tucumán, it is very important to consider how production costs may be lowered without impairing yields and quality of output. The Petree process has for its objective the elimination of the filter press station with its costly upkeep in filter press cloths, labor, extra evapn., and addnl. lime, and to increase the capacity of the evaporators and of the mills. All of these items of saving being reviewed, it was found over a period of 4 years that the saving amounted to \$0.47 (Argentine currency) per ton of cane and about \$0.06 per 10 kg. of sugar; the answer is that it does pay.

The maintenance of vacuum in sugar factories. ALFRED L. WEBER. *Facts About Sugar* 24, 233-6, 254-7(1929).—W. discusses the pressure relations required, the functions of vacuum pumps and condensers, the effects of condenser-water temp., selection of condensers, the advantages and disadvantages of the use of individual condensers for each evaporator or pan versus central condenser plants, and the advantages of multijet condensers versus vacuum pumps. The article is well illustrated with charts.

The lime kiln in the sugar factory. A. BERINGER. *Sucr. Belge* 48, 61-9, 81-7, 141-50, 164-70, 181-90(1928-29). The subject is discussed at great length. The theoretical side is well handled, and conclusions are drawn as to the practical application of the theory. The following topics are covered: ratio of C to CaCO_3 ; ratio of air to C; time of contact of solid and gas; relative size of the C and CaCO_3 ; irregularities of the currents; relative speed of the currents; control of the kiln. An analysis of the phenomena which occur in a kiln is given.

Conductivity ash determination in sugar factories in Natal and Mauritius. R. G. W. FARNELL. *Intern. Sugar J.* 31, 86-7(1929); cf. *C. A.* 21, 1025, 2569, 2394; 22, 2677. —The results of work with the "Salometer" in some factories in Natal and Mauritius are reported. The factors correlating cond. and gravimetric ash were detd. experimentally and found to agree with those of Zerban and Lundén. The ash throughout is higher in Natal than in Mauritius raw sugar factories. The high chlorides in Natal juices are notorious and adversely affect the recovery. There is invariably an increase in ash during clarification by sulfo-defecation. In the raw sugar factory the cond. ash method provides the chemist with a new simple means of controlling the clarification, since an excessive rise in cond. points to irregularities in defecation.

Rapid method for the determination of phosphoric acid in sugar factory and refinery products. R. G. W. FARNELL. *Intern. Sugar J.* 31, 149-52(1929). The important role of phosphates in clarification of cane juices is now being generally recognized. It is known that the P_2O_5 content of mixed juices should be about 0.005 or over, and in Natal this is sometimes raised to 0.05 or 0.06 on account of the high colloid content of the juice. It is highly desirable, in order to insure the satisfactory clarification of cane juices, to det. the P_2O_5 content of the juices and to increase it when necessary. A rapid method for the detn. of P_2O_5 would be very valuable as a method of control in sugar house operations. The coeruleomolybdate method of phosphate detn. depends on the formation of a blue color formed on the addn. of acidified NH_4 molybdate to a very dil. phosphate soln., followed by a few drops of SnCl_2 . Two solns. of reagents are required: (1) 25 g. of NH_4 molybdate dissolved in 250 cc. of H_2O .

* Doctor Dale has kindly consented to do the editorial work for this section while Dr. F. W. Zerban is away on a trip of several months. Dr. Zerban has gone to Java. He will resume charge of the section on his return to the United States.

to which is added 750 cc. of H_2SO_4 , 50% by vol.; (2) 0.1 g. pure tin dissolved by warming in 10 cc. of concd. HCl , to which is added one drop of a 4% soln. of CuSO_4 . The standard phosphate solns. are prepd. as follows. (A) A soln. of 1.34 gs. of $\text{Na}_3\text{PO}_4 \cdot 12\text{H}_2\text{O}$ in 250 cc. of H_2O contains 1 mg. P_2O_5 per cc. This soln. is diluted to make standards contg. 0.01 and 0.005 mg. of P_2O_5 per cc. The color developed in solns. tested with standard reagent is compared with that of the standards. 97.1% of the P_2O_5 in the treated juices is removed as $\text{Ca}_3(\text{PO}_4)_2$ during the clarification and settling, at a pH of 7. Experience has shown that the application of phosphatic fertilizers to the soil increases the P_2O_5 of the mixed juices from the cane grown on the soil.

W. L. OWEN

The control and accounting of a cane sugar factory. R. H. KING. *Planter and Sugar Mfr.* 81, 261-3, 283-300(1928).—A complete and critical discussion of chem. control and sugar accounting.

J. F. BREWSTER

The cane sugar industry of Spain. J. VAN HARREVELD. *Planter and Sugar Mfr.* 81, 161-3(1928).—See C. A. 22, 4857.

The respective merits of the P. O. J. 36, 213 and 234 canes in Argentina. W. E. CROSS. *Planter and Sugar Mfr.* 81, 421-4(1928).—From a partial census of the cane varieties grown in Argentina the relative merits of the 3 varieties are discussed on the basis of germination, growth habit, response to fertilizer, resistance to frost and to diseases and pests, fiber content, yield, etc. Preference is in favor of P. O. J. 36 while the use of 234 has practically ceased.

J. F. BREWSTER

A clean culture system of sugar cane insect control. W. D. PIERCE. *Planter and Sugar Mfr.* 81, 481(1928). Ratooning may sometimes be a disadvantage in the Philippines. Elimination of grass and weeds is recommended.

J. F. BREWSTER

Tillage and cultivation practices which will aid in field drainage. GENEROSA VILLANUEVA AND ATHERTON LEE. Philippine Sugar Assoc. *Planter and Sugar Mfr.* 81, 461-2(1928). Standing water on cane fields is held to be the worst enemy of the cane in the Philippines. Methods of promoting drainage are suggested.

J. F. BREWSTER

Studies in sugar cane physiology: germination gradients. AUGUSTO BONAZZI. *Planter and Sugar Mfr.* 81, 181-3, 203-19, 225-39, 244-60(1928).

J. F. B.

Sugar cane seedlings. J. A. VERRET. *Facts About Sugar* 24, 182-5, 189(1929); cf. C. A. 22, 2677. Extensive expts. on the preservation of cane seed in the atms. (a) air, (b) O_2 , and (c) CO_2 , with various degrees of desiccation for each gas, leads V. to recommend the following procedure: Air-dry the tassels promptly, using a desiccated atm. if necessary, until the fuzz is crisp and shatters easily. Strip the fuzz from the tassels and place it in cans. Introduce CO_2 to displace the air. Desiccate the atm. with 9 g. CaCl_2 for each 1000 cc. of the volumetric capacity of the can. Place the CaCl_2 in four or five small cans covered with cheesecloth and distribute these cans throughout the fuzz mass in each seed can. Again introduce CO_2 , cover the seed cans and seal them air-tight with paraffin or sealing wax. Place the sealed cans in cold storage at 31°F . The whole procedure from cutting the tassels to placing in cold storage must be carried out within 7 days. Some of the seeds will be viable even after 9 months. Covering the fuzz in the germination flats with a thin dressing of volcanic ash is distinctly beneficial. The article contains a description of the methods used in the Hawaiian centralized cane-breeding work and a summary of the replies to the questionaire on seedlings.

M. J. PROFFITT

The gummosis of sugar cane. MELVILLE T. COOK. P. R. Insular Agr. Expt. Sta. Rio Piedras. *J. Dept. Agr. P. R.* 12, 143-79(1928).—Gummosis of sugar cane is a bacterial disease caused by *Bacterium vascularum*. The organism lives in the tracheary tissues of the fibrovascular bundles. Sometimes it dissolves the cell walls and spreads into the surrounding tissues of susceptible canes and into young tissues of somewhat resistant canes. The organism produces a gum which oozes out of the cut ends of the infected canes. The disease kills many young canes and causes a reduced yield, varying with the susceptibility of the variety and the severity of the attack. The gum interferes seriously with the crystn. of the sugar in the mills. The % of infection is higher on plant than on ratoon cane, but in all cases the yield on the ratoons was reduced. The leaf symptoms are more pronounced during wet than dry

weather. Many of the best varieties in P. R. are immune or highly resistant. Infected cane should never be used for com. planting. C. R. F.

The purchase of cane by its analysis. E. E. DOMINGUEZ. *Facts About Sugar* 24, 88-91, 95(1929).—Formulas and a method of operation of a proposed new system for Cuba are given. M. J. PROFFITT

Individual composition of sugar canes in a furrow and its importance in the method of sampling for analyses. WM. E. CROSS, A. S. ALVAREZ AND ISAAC MENOFF. *Rev. ind. agr. Tucumán*. 19, 141-5(1928).—The yield in the factory often differs from that calcd. by the planter or the Expt. Sta. (Tucumán). This has hitherto been explained by the difference in extn. conditions. But there is now found to be considerable variation in wt. and chem. compn. of stalks in the same furrow. Wts., Brix, sucrose and purity are given for 493 cane stalks; it is concluded that the custom of estg. the yield from a field or row of canes from the analysis of 1 or 2 stalks or even 3, may lead to erroneous results. A probability table of errors is shown for analyses of samples of 5, 10 and 20 canes. A sampling method is given, which uses at least 20 stalks. S. L. B. ETHERTON

The Maxwell crusher shredder. ANON. *Intern. Sugar J.* 31, 24-5(1929).—A report of the Java Sugar Expt. Sta. on the Maxwell crusher shredder, verifying the guarantee that the Popah factory would obtain with its milling train of a crusher shredder, 30 × 60 in., and 3 mills, 32 × 72, at a crushing capacity of 1100 tons daily, the same results as obtained in a similar factory having a crusher and 4 mills. Conclusion: A Maxwell shredder roller equals one mill. W. L. OWEN

Yield determination from crusher juice analysis. J. A. ROIG. *Facts About Sugar* 24, 283(1929).—For judging the quality of the cane being ground, R. proposes a formula which is based on the sucrose content and on the Brix of the crusher juice, but which involves also various "constants" that are characteristic of the individual factory's performance, including its Java ratio (sucrose in crusher juice/total sucrose in cane). M. J. PROFFITT

Cane-wax complex in juices from cane-sugar mills. C. F. BARDORF. *Ind. Eng. Chem.* 21, 366-8(1929).—Evidence from the migration of the cane-wax complex traced through 4 Cuban mills shows that the complex remains stable throughout all of the process of the mill, whether the source of the juice is from normal, old, or dead canes. C. F. ROGERS

Insoluble solids in raw cane juice. E. M. CORP. *Facts About Sugar* 24, 210-1(1929).—C. describes a method of computing the quantity of insol. solids from the data ordinarily recorded in sugar mills. M. J. PROFFITT

Digestion of sugar juices. BEDŘICH NEUMAN. *Listy Cukrovar.* 47, 330-2(1929). A sample computation of yields in a refinery gained in the last season. F. M.

Methods of boiling sugar. ANON. *Intern. Sugar J.* 30, 652-5(1928).—A discussion of the methods of sugar boiling in Cuba, Hawaii, Argentina and Queensland, at the Second Conference of the Intern. Society of Sugar Cane Technologists. W. L. OWEN

Judging sugar by taste. A. A. RICHTER. *Zhurnal Opuitnoi Agron. Yugo Vostoka (J. Exptl. Landw. Sudost. Eur.-Russlands.* 3, 101-6(1927); *Exptl. Sta. Record* 58, 611). Various concns. of solns. of glucose, sucrose and fructose were prepd. in the same manner and placed in beakers; 10 cc. of each was tasted, and the presence, absence or doubt of presence of sugar was recorded. From these data the ratio of sweetness was estd. as follows: fructose 100, sucrose 66, glucose 45. H. L. D.

Molasses formation. O. SPENGLER, F. TÖDT AND CH. SHEN. *Z. Ver. deut. Zuckerind.* 78, 747-59(1928).—The results of Schukow (*Z. Ver. deut. Zuckerind.* 1900, 291-321) on the soly. of sugar in salt solns. are recalc'd. It is shown that the power of the salt for increasing the soly. of sugar is inversely proportional to the degree of hydration of the salt. This was checked by cond. measurements. Detns. of the salt-sugar solns. show a relationship between salting-out action and the mol. vol. of the salt. The work shows that a highly hydrated salt has a low equiv. cond. and a small tendency to dissolve sugar, while a salt with a low hydration has a high cond. and a great tendency to dissolve sugar. The series in order of affinity for sugar is KBr, KCl, NaCl, LiCl. Thus, if the same amt. of sugar is added to solns. of LiCl and of KBr, the sugar would have the greatest effect on the cond. of the LiCl. It is shown that for salt solns. below 0.1 N the affinity of salt for water is without influence on equiv. cond.; thus in dil. solns. the affinity of salt for sugar can be observed. This gives a series of salts which one would expect from Schukow's work. E. A. F.

Influence of the basicity of basic lead acetate in the clarification of molasses solutions. R. SOMMER. *Z. Zuckerind. Tschoslovak. Rep.* 53, 45-52(1928). The basic Pb ace-

tate prescribed for sugar analysis contains 31.9% of its Pb in the form of oxide. If solns. contg. a higher proportion of oxide to normal acetate are used, lower values are obtained for the polarization of beet molasses, assuming that the same total amt. of Pb is used for a given wt. of molasses. If the defecant contains 57% of its Pb as oxide, it may lower a molasses polarization of 50 by 1-2 units. The extent of the lowering is a direct function of the original alky. (p_H value) of the molasses; but no alky. likely to occur in practice will produce any lowering when basic Pb acetate of the usual compn. is employed. The decolorizing effect (always assuming the use of the same total amt. of Pb for a given wt. of molasses) increases with the proportion of PbO until this reaches 39-52%, but beyond this limit it diminishes rather rapidly. With 48% of the total Pb as oxide, decolorization is much better than with the usual proportion; the lowering of polarization can be prevented by previous neutralization of the soln. with acetic acid.

B. C. A.

Vegetable char refining on the plantation. J. P. FOSTER. *Intern. Sugar J.* 30, 595-8; *Planter and Sugar Mfr.* 81, 304-5 (1928).—F. reviews the arguments that have been published in favor of the manufl. of refined sugars by the sugar factories both in La. and in Cuba, and concludes that the arguments for the latter country apply as aptly to Hawaii. At present there is no incentive to make 98 or 99 test sugar; to do so means a penalization for the extra polarization of these grades. There is no difficulty of redesigning the av. sugar factory so as to have an adequate supply of fuel for refining. Much of the app. used in refining is a duplication of the equipment used in raw sugar manufl. The cost of erecting a sugar refinery for the use of vegetable chars in connection with a sugar factory may be roughly estd. at \$120,000 for a 100-ton plant, \$200,000 for a 200-ton plant, and \$275,000 for a 300-ton plant. The cost of refining with vegetable char on a La. estate has been estd. at 25.1cts. per 100 lbs. during the grinding operations and 45.7cts. during the dead season.

W. L. OWEN

The behavior of oxalic acid during clarification. O. SPENGLER AND C. BRENDL. *Z. Ver. deut. Zuckerind.* 78, 729-46 (1928).—Ca oxalate is found in the scale of the 3rd cell of the evaporators. A series of lab. expts. is described. Conclusions: (a) The soly. of Ca oxalate is altered only slightly, ranging from 0.0008 to 0.0010% for sugar solns. of 12 to 60° Brix.; the temp. has hardly any effect. (b) Ca oxalate goes into soln. in not insignificant quantities during the liming of the juice; but these quantities are reduced to the low figure of some 0.001% Ca oxalate in the first carbonatation. In the second carbonatation the Ca oxalate still present in soln. is changed into CaCO_3 or CaSO_4 by double decompn. with Na_2CO_3 or Na_2SO_4 , while the oxalic acid remains in soln. as alkali oxalate, and, because of the presence of sufficient natural alky., is not able to be converted into Ca oxalate. In practice sometimes a heavier scale than can be expected is formed in a very short time. Here one may assume as a most probable explanation for the great amt. of Ca oxalate found in the scale, that the non-sugar, perhaps colloids, hinders the pptn. of the Ca oxalate in the first carbonatation; that the amt. of Ca oxalate present in soln. remains as such, and that in the final carbonatation it is not transformed if the natural alky. is low even for a short time. E. A. F.

Cleanliness for evaporators. LOUIS BORSY. *Sucr. belge* 48, 201-5 (1928).—A review is given of hand and mech. devices for removing incrustations from evaporators. The advantages of the new Devoorde mech. scale-remover are discussed. E. A. F.

Methods for determining the speed of crystallization. M. I. NAKHMANOVICH AND I. F. ZELIKMAN. *Nauchnuie Zapiski* 6, 32-53 (1928).—A review of the literature.

V. E. BAIKOW

Experiments on measuring the speed of crystallization of sucrose from beet products. M. I. NAKHMANOVICH AND I. F. ZELIKMAN. *Nauchnuie Zapiski* 6, 109-22 (1928).—Kukhareenko's method was used. The relation between concn. of non-sugars and speed of crystn. was investigated, but not the influence of viscosity or compn. of non-sugars. First and second massecuites and greens were used, with a purity of 90, 80 and 70%, resp. The speed of crystn. was calcd. by the formula: $\eta = (\Delta M / (s \times t))$, where ΔM is the wt. of sugar in the surface of the crystal in mg.; $s = (4.12 \sqrt[3]{M^2})$ is the av. surface of the crystal in sq. mm.; t is the duration, in min., of the contact of the crystal with the soln.; M is the wt. of the crystal. Expts. were made to det. the relation between speed of crystn., degree of supersatn. and purity. It was found that for materials of high purity the rate of crystn. increased very rapidly with increasing supersatn. With low purity products (about 70) increase of supersatn. produced only a slight increase in speed. For any given purity the speed of crystn. was found roughly proportional to the coeff. of supersatn. Increase of concn. of non-sugars in factory products sharply lowered the speed of sucrose crystn. The results of lab. expts. and factory work were somewhat different, but this is due to the modern crystallizers, which

should be modified because only large lumps of fillmass are mixed and diffusion is not sufficient. A no. of tables and diagrams are shown. V. E. BAIKOW

Significance and determination of temperature coefficients in the study of inversion. V. ZAFOUK. *Z. Zuckerind. čechoslovak. Rep.* 53, 73-9(1928).—Measurements of the inverting capacity of weak acids at different p_H values showed that no inversion occurs beyond about p_H 6. The p_H values of solns. of weak acids, or of mixts. of the acids and their salts, vary to some extent with temp.; the variations are not the same with different acids; differences up to 0.1 in p_H value were observed between 20° and 70°. Curves are given showing the p_H values and corresponding temp. coeffs. for different stages of neutralization of succinic, aspartic, acetic, glutimic and glutamic acids. For practical purposes a factory juice which is slightly alk. to phenolphthalein will be safe from inversion, provided it has no tendency to become more acid in course of time or on heating. B. C. A.

Studies of the diffusion liquors with respect to the possible inversion of sucrose and effect of microorganisms. VOJTECH MAKEŠ. *Listy Cukrovar.* 47, 290 4(1929); cf. C. A. 22, 2481.—Previous investigations show that diffusion liquors contain 0.1% more invert sugar than beets, and that the increase seems to be due to the acid reaction of the liquor. Diffusion liquors were digested at 90° for as long as 6 hrs. with and without lime. The difference in polarization between the two liquors is greater than can be effected by CaO and is ascribed to the acidity of the juice, for enzyme or microbiological action is not possible at 90°. The purification of the liquor progresses further at 90° than when the CaO is added to a cold soln. A yeast growth upon a batch of liquor showed a predominance of *Torula utilis* Henneberg, which grows upon glucose-agar media in circular, gray colonies of concentric layers and elevated centers. The forms of yeast are irregular, elongated, coarsely granular and without vacuoles. The content of glycogen and albumin depends upon the type of media used for culture. The structure is greatly influenced by the N_2 present in the substrate. This yeast is not a spore former and ferments glucose, fructose, maltose and sucrose. It has an optimal temp. slightly above 30° and a max. at 40°; in diffusion liquors a fruity odor is evolved. It is also widely distributed with vegetation, H_2O , soil, etc. *Zygosaccharomyces* was also isolated from the same batch. It ferments, intensively, a 10-20% soln. of sucrose, glucose and fructose and forms a cloudy sediment, which settles well and is not covered by a scum. In sugar solns. or on a substrate of solid sugar, a weak fruity odor is evolved. The forms are round or oval; older forms become granular and contain vesicles, but do not contain vacuoles as a rule. Upon agar 1-3 round spores form, and prior to their formation, copulation of the yeast cells occurs; this act differentiates them from *Saccharomyces cerevisiae*. To 1 l. of sterile diffusion liquor is added 2.62 g. of yeast cells settled in the basin and maintained at 30° (the 2.62 g. represents the concn. of cells in the soln. in the factory basin). The polarization during 15-min. intervals shows a drop of 0.97% during the 1st interval and continues to act more rapidly. Fermentation changes the p_H from 5.9-6.1 to 5.1-5.2 with an evolution of CO_2 and great amount of foaming after shaking. The odor is mild and fruity. An addn. of 0.25% Ca before fermentation stops or prevents the action of yeast cells. M. advises the addn. of CaO as a preventive of losses of sugar in infected liquors which cannot be sterilized by heat; in normal juices the addn. of CaO has a bad effect upon subsequent purification of said solns. FRANK MARSH

Steam accumulators. J. LEWIS RENTON. *Intern. Sugar J.* 31, 19 23(1929). This is an app. that stores the heat energy of steam at satn. pressure and temp. and releases this energy in the form of steam under decreasing pressure. It enables the plant load to fluctuate between wide limits without necessitating any change in the firing of the boilers to maintain uniform steam pressure. The 2 types in use are the high-pressure flash type and the large-capacity storage type. The high-pressure type is not applicable to sugar house work, but the large-capacity storage type has found wide application in the industries of Europe and is receiving much attention in America. The advantages claimed for the Ruths steam accumulator are: reduction in fuel consumption, reduction in boiler maintenance, simplification in boiler control, maintenance of const. steam pressure, maintenance of uniformity of product, increase of production and reduction in initial cost of new boiler installation, and increase of steam-generating capacity. W. L. OWEN

Deposits in the carbon dioxide pipes. O. SPENGLER AND C. BRENDEN. *Z. Ver. deut. Zuckerind.* 78, 644-5(1928).—During the last campaign white-gray deposits were noticed in the valves of the CO_2 pumps, in 2 factories, reducing the efficiency of the pumps. The phenomenon has been previously recorded on several occasions. The deposit consists mostly of K_2SO_4 , Na_2SO_4 , and some NaCl. It is thought that

the alkali sulfate is volatilized from the kiln as alkali carbonate, which later combines with the SO_2 from the coke. On locating the place where the deposit is formed, steam and water may be used to wash it off. Tarry matter may be removed from the valve chambers of the pumps by the injection of petroleum.

The performance of the continuous diffusion battery of E. R. Kraevskii. I. DUSH-SKII, *et al.* *Nauchnuie Zapiski* 5, 380-3 (1928).—A committee report. E. A. FIEGER

29—LEATHER AND GLUE

ALLEN ROGERS

Standards in the leather industry. C. H. SPIERS. *J. Intern. Soc. Leather Trades Chem.* 12, 602-8 (1928).—Standards imply specifications, and the promulgation of a specification implies (1) that it is known what the desirable qualities are; (2) that these qualities can be measured; (3) that it is known what the most desirable value for each desired and measurable quality is and (4) that the manuf. process is such that the specified values can be attained in practice with reasonable effort. The state of affairs regarding specifications in the leather industry is reviewed. *Hides and skins.*—Virtually no specifications exist. Specifications defining and limiting physical defects, method of curing, % H_2O_2 and % mineral matter could and should be drawn. *Accessory materials.*—Most of these are more or less homogeneous and capable of analysis. The lack of specifications in buying these materials is not justified. *Tannery liquors and semi-finished products.*—Methods of analysis exist but interpretation of results is often difficult. Each tannery should work out a set of data corresponding to normal working. *Finished leather.*—Here the tanner often cannot avoid working to specifications. It is very difficult to connect up desirable qualities with conventional, measurable qualities. Existing specifications cover very few types of leather, and most of them are defective. The situation may improve in the near future as the result of committee work now in progress.

Casein in the leather industry. G. GENRIN. *Halle aux cuirs* 1928, 373-8; 1929, 13-9.—A review. H. B. MERRILL

Determination of (enzyme) strength of a bate. ALBERT BOLDIN. *J. Intern. Soc. Leather Trades Chem.* 12, 614-25(1928).—The casein method has been adopted by the I. S. L. T. C. for detg. the enzyme strength of a bate. Expts. were undertaken to det. the effect of various factors upon that method. The procedure consisted in digesting casein soln. with different concns. of enzyme, acidifying, filtering undigested casein, and detg. digested casein (1) from the wt. of ppt. and (2) from the N content of filtrate. In general both methods gave the same results. Two specimens of pancreatic enzyme, and 2 bacterial cultures were employed. p_H value of pptn.—Complete pptn. is obtained at p_H = about 4.6, and the p_H value may be lowered to 2.5 without redissolving any casein. *Buffer salts.*—Phosphates retard the digestion and are difficult to wash out of the ppt. Casein dissolved in the vol. of NaOH previously detd. to give a soln. of p_H = 7.5-7.6 is in itself a good enough buffer to maintain the constancy of the p_H value within 0.1-0.2 unit. p_H value of digestion.—For pancreatic enzyme, the optimum is at p_H = 8. Bacterial enzymes have a wide optimum range. *Method of dissolving casein.*—Quantity of sol. N in a given specimen of casein is const., regardless of whether the casein is dissolved at 40° or at 100°. *Time of digestion.*—The rate of digestion falls off after 1 hr., which period is recommended. *Temp. of digestion.*—The rate of digestion increases with temp. up to 60°. Temp. has more effect on pancreatic than on bacterial enzyme. *Effect of hydrolysis products.*—Hydrolyzed casein inhibits the pptn. of unhydrolyzed casein. A mixt. of 16 parts of unaltered casein with 84 parts of hydrolyzed casein gave no ppt. upon acidification. For this reason, any method employing the complete digestion of casein as an end point is bound to be in error. H. B. MERRILL

Tannins. HELMUT THALER. *Mikrokosmos* 22, 94-6(1929).—A description of the chem. reactions and histology of the vegetable tannins. Photomicrographs of sections fixed with formol and stained with $Fe(NH_4)_2(SO_4)_2$ show the occurrence of tannin in (1) pine needle, (2) branch of *Betula verrucosa*, and (3) seed of *Adacta spicata*. H. B. M.

Influence of tannin on the p_H value of different acids. N. CHERNOV and S. SIPINA. *Vestnik (Organ of the All-Russian Leather Syndicate)* 1927, No. 8, 285; *Collegium* 1929, 45.— p_H values of solns. of HCl, H_2SO_4 , HOAc and lactic acid, dild. from 0.1 N to 0.02 N with H_2O and with 1° Bé. solns. of different tanning exts., are tabulated. All tanning exts. lower the H-ion concn. more than H_2O . The effect is greatest for weak acids. The magnitude of the rise in p_H value varies with the material. H. B. MERRILL

Determination of insolubles in tanning extracts. ANDREW TURNBULL. *J. Am. Leather Chem. Assoc.* 24, 121-4(1929); cf. *C. A.* 22, 2681.—A filtering layer of kaolin is formed on a porous glass septum in a Buchner funnel. Non-plastic kaolin is made by grinding white fireclay brick to pass a 100-mesh sieve, digesting with HCl and HNO_3 , washing with water, and mixing with 0.1 part of ordinary kaolin. McCandlish and Atkin's filtration app. is used. The results obtained check satisfactorily with the filter candle method and the filter paper-kaolin method. H. B. MERRILL

Tanning experiments with synthetic tanning materials. J. BERKMANN. *Vestnik (Organ of the All-Russian Leather Syndicate)* 1928, No. 5, 211-3, No. 6/7, 203-6; *Collegium* 1929, 35-9.—Analyses are given of leathers tanned with a wide variety of mixt. of synthetic, vegetable and chrome tanning materials. H. B. MERRILL

Chrome tanning. XVIII. Analytical figures for leather, especially chrome. D. BURTON and H. CHARLTON. Wm. Walker & Sons, Ltd., Bolton, Eng. *J. Intern. Soc. Leather Trades Chem.* 12, 210-6(1928); cf. *C. A.* 22, 4269.—The sum of the percentages of grease (gasoline ext.), H_2O -sol. matter, ash, hide substance and H_2O should be slightly less than 100. Analyses of numerous leathers show that the total is frequently 5-12% less than 100. This is attributed: (1) To failure of gasoline to ext. all fatty matter. Material not extd. by gasoline and not included in any other analytically detd. quantity includes (a) some animal skin fat, (b) sulfonated oil, (c) neutral soap, (d) oxidized fat (e) rosin, and (f) S. Data are presented illustrating (b) and (d). (2) To failure to ext. all matter sol. in H_2O . (3) To interference of grease in waterproofed leathers with the Kjeldahl detn. of N. It is recommended that such leathers be degreased before Kjeldahl digestion. The Hg-displacement method for detg. sp. gr. is advocated. H. B. MERRILL

Effect of heat on wetted vegetable-tanned leathers. H. W. J. CHATER. Northampton Tech. Coll., Northampton, Eng. *J. Intern. Soc. Leather Trades Chem.* 12, 608-14(1928); cf. *C. A.* 23, 1768.—Strips of pelt pretreated with acid, alk. and mineral solns. have characteristic shrinkage curves. Leather contg. excessive amts. of mineral acid begins to shrink at a lower temp. than normal leather. This is advocated as a method of detecting mineral acid. H. B. MERRILL

Effect of neutralization of chrome leather upon fat absorption. HENRY B. MERRILL and JOSEPH G. NIDDERCORN. *Ind. Eng. Chem.* 21, 364-6(1929).—When Cl₂ is thirt

samples were neutralized with increasing amts. of either borax or NaHCO_3 and subsequently fat-liquored with sulfonated neatsfoot oil, the samples from which the least H_2SO_4 was removed took up the most oil, when the fat-liquor contained an excess of oil and when the time of fat-liquoring was 30 mins. Upon increasing the time of fat-liquoring, the amt. of fat taken up by the more completely neutralized samples approached that taken up by the samples contg. the most H_2SO_4 . The excess oil absorbed by the more incompletely neutralized samples is found entirely in the surface layers of the skin. The quantity of oil absorbed is not a function of the pH value of the neutralizing bath, except insofar as this det. the amt. of acid left in the leather. The effect is explained as due to the lowering of the p d between oil droplets and skin which results from neutralization of the leather.

H. B. MERRILL

State of combination of acid sulfate in chrome leather. HENRY B. MERRILL AND JOSEPH G. NIEDERCORN. A. F. Gallun & Sons, Milwaukee. *Ind. Eng. Chem.* 21, 252-3 (1929).—Previous work has shown that much of the acid sulfate of Cr-leather is attached to Cr, and that the diffusion-neutralization titration with methyl red is the most reliable means for detg. protein bound sulfate. From the behavior of the leather in neutralization it is deduced that the difference in hydrolyzability between protein-bound and Cr-bound sulfate is so small that if all the former is removed more will be regenerated by hydrolysis of the latter. From this it follows that the % of protein-bound acid is a function of the acidity of the sulfato-chromi complex. This is shown experimentally to be the case for leather contg. a sulfato-chromi complex of acidity = 0.17-0.33. When acidity is < 0.17, no protein bound sulfate is present, and if leathers of acidity 0.33 are treated with acid, all the acid taken up is protein bound.

H. B. MERRILL

Removal of chrome salts from leather. F. C. HEMMINGS AND M. C. LAMB. Leathersellers' Tech. Col., London, Eng. *J. Intern. Soc. Leather Trades Chem.* 12, 599-602 (1928).— $(\text{NH}_4)_2\text{C}_2\text{O}_4$ has long been known as a stripping agent. Free $\text{H}_2\text{C}_2\text{O}_4$ works much more rapidly. The liquor produced is deep purple, turning to green on addn. of NH_3 . $\text{Cr}(\text{OH})_3$ is not pptd. even on boiling. NaOH ppts. $\text{Cr}(\text{OH})_3$ on long boiling. Na phosphate gives no ppt., and CaCl_2 only a very slight ppt. even on boiling. The soln. contains an oxalato-chromate, perhaps trioxalato chromium, $\text{Cr}(\text{C}_2\text{O}_4)_3$, described by Werner. To form trioxalato chromium, Cr-leather shaving contg. 4% Cr_2O_3 would require 10 lbs. $\text{H}_2\text{C}_2\text{O}_4$ per 100 for complete stripping. This proportion was tried, and complete stripping was obtained in several days, but quicker results were obtained by using 15 parts per 100 of $\text{H}_2\text{C}_2\text{O}_4$, and by washing out with NH_4OH , probably because NH_4 oxalato-chromates are more sol.

H. B. MERRILL

Properties of shoe leather. VII. Temper and break. JOHN A. WILSON. A. F. Gallun & Sons Corp., Milwaukee. *J. Am. Leather Chem. Assoc.* 24, 112-9 (1929); cf. C. A. 20, 3005.—Temper has 2 component factors, flexibility and recovery. An app. for measuring both factors is described. A strip of leather 1×6 in. is bent into a circle of exactly 4 cm. diam., and secured to a block. A scale pan suspended from a coil spring is made just to touch the leather by adding weights, and the addnl. weight (called W_1) required to crush the circle to $\frac{1}{4}$ its initial diam. is detd. Allowance is made for the thickness of the leather. The weight (W_2) required to lower the pan to the same level in the absence of the leather is detd. The flexibility factor, in g., is the difference between W_1 and W_2 . Flexibility factors, and % recovery are given for 16 leathers. The recovery factor is measured by noting the percent of return to the initial diam. after removing the wts. Bellies have lower flexibility factors than butts, but percent recovery varies very little. Splitting lowers the flexibility factor without having much effect on recovery. Break is measured by counting the wrinkles per cm. in a strip of leather drawn tightly around a glass rod 3.2 mm. in diam., grain side in. Values for break of 16 leathers are given.

H. B. MERRILL

Dyeing of goatskins. FRANK H. SCHORTEMAYER. *Dyestuffs* 30, 17-21 (1929); cf. *Leather* 2076.—Bark-tanned goatskins are usually retanned with chrome when good color penetration is desired as in stock for suede or grain finished leathers. Formulas, procedures and suitable dyes are suggested for clearing, retanning, dyeing, fat-liquoring and finishing the stock for both the suede and grain finish.

DON BROUSE

Consistency and gel formation (WAGNER) 2.

Borax and Boric Acid in the Tannery and Currying Shop. New York, Chicago and Oakland: Pacific Coast Borax Co. 96 pp. Gratis.
Gerbereichemisches Taschenbuch (Vagda-Kalender). 2nd ed., revised and enlarged. Edited by the Vereinigung akademischer Gerbereichemiker Darmstadt. Dresden and Leipzig: Verlag von Theodor Steinkopff. 218 pp. M 7.50.

Tanning leather. HERMANN BOLLMANN and BRUNO REWALD. Fr. 647,456, Jan. 18, 1928. An ingredient for facilitating the tanning of leather is obtained by swelling in water, or fatty oil such as fish oil, or fatty oil and sulfonated oil, lecithin of animal or vegetable origin with final soln. or emulsification in water. The mixt. contains a certain amt. of alkali or soap.

Tanning and finishing skins. MYRON LASKIN. U. S. 1,708,020, April 9. After tanning and buffing the flesh side of a skin the latter is treated with an aq. soln. of direct aniline black dye and gum tragacanth, and, after drying, the flesh side is further treated with a compn. formed from beeswax or carnauba wax soln., shellac, casein, albumin, oil of mirbane, prepd. blood, lampblack and water; after further drying, a shellac, casein and albumin coating is applied, and the flesh side is then dried and finally glazed or polished.

Textile fibers from fish skins. ALFRED EHRENREICH. 647,030, Jan. 13, 1928. Skins of fish, particularly chondropterygian selachians, are treated with lime and then submitted to the action of diastatic enzymes, rinsed and tanned for the production of textile fibers. Cf. *C. A.* 22, 4835.

Impregnating leather. OTTO RÖHM. Ger. 471,675, May 9, 1925. Addn. to 470,552. The method of Ger. 470,552 (*C. A.* 23, 1770) is modified by using, instead of water, an aq. soln. of substances having a clarifying or slight bleaching effect on the leather. Suitable substances are alkalies, e. g., NH_3 , alk. salts, e. g., Na_2CO_3 , and org. acids, e. g., $(\text{COOH})_2$.

Powdered-leather agglomerate. J. M. GONNISEN. Belg. 351,717, June 30, 1928. Leather dust is mixed with an adhesive prepd. by an acetone soln. of celluloid, the resultant paste is put through a press or is molded, and after removal of the excess of adhesive the articles are allowed to dry.

Artificial leather. E. I. DU PONT DE NEMOURS AND CO. Fr. 647,255, June 21, 1927. Artificial leather consisting of a fabric support and a film of a cellulose ester, e. g., pyroxylin, has a superficial layer which will reduce surface tension and is impermeable, non-viscous and flexible, preferably of casein mixed with a polyhydric alc. such as glycerol.

Imitation leather. E. KATZ. Brit. 206,661, Sept. 3, 1927. A fabric is finished with a dressing compn. contg. starch, calendered under high pressure, and treated with a dye (suitably an aniline dye) so as to produce an indistinct design, dried, treated with dye again (preferably of a darker shade than that first applied) and again dried. This treatment may be repeated, followed by further calendering and ornamentation such as graining.

30—RUBBER AND ALLIED SUBSTANCES

C. C. DAVIS

The oxidation of vulcanized rubber. A. VAN ROSSEM and P. DEKKER. Staatl. Kautschuk Forschungs-Institut, Delft. *Kautschuk* 5, 13-21 (1929). The expts. represent a systematic study of the nature of oxidation of vulcanized rubber. A rubber, S (97.5-7.5) mixt. was cured to different degrees, the vulcanizates were finely divided, were then stored exposed to air in diffused light, and periodically up to 18 months their wts., acetone exts., free S, combined S, alc. KOH ext., oxidation products in the alc. KOH ext. and aq. exts. were detd. The alc. KOH exts. were detd. by swelling the acetone-extd. samples in C_6H_6 , extg. with alc. KOH, filtering, washing, evapg. to a small vol., dissolving in water, acidifying and extg. with Et_2O . The products consisted of oxidation products and fatty acids from esters which were insol. in acetone. The alc. KOH ext. was a very sensitive quant. measure of the extent of oxidation, for it began to increase much sooner than did the acetone ext., reaching around 1/2 its original value before the acetone ext. increased appreciably. The aq. ext. increased even more slowly than did the acetone ext. When oxidation was extensive, a part of the alc. KOH ext. was insol. in Et_2O , so that detns. were impracticable beyond a certain stage of oxidation. The proportion of oxidation products in the alc. KOH ext. was detd. by boiling the dried original alc. KOH ext. with 0.5 N alc. KOH, extg. the insol. residue with water and drying the raw residue at 100° (cf. Dekker, *C. A.* 21, 195). A special investigation showed that (1) swelling with C_6H_6 was essential for accuracy in the detn. of the alc. KOH ext.; (2) equal parts of C_6H_6 and alc. should be used, and (3) if the sample swollen in C_6H_6 was extd. with alc. alone instead of alc. KOH, the oxidation products were extd. During the early stages of oxidation, the oxidation products were insol. in acetone, but were sol. in C_6H_6 -alc. mixt. and in Et_2O .

As oxidation progressed, products were formed which were sol. in the C_6H_6 -alc. mixt. but not in Et_2O . Extn. with $CHCl_3$ after the acetone extn., and the temp. of drying of the alc. KOH ext. and of the oxidation products, were both without material influence on the detn. of the oxidation products. During oxidation the proportion of oxidation products increased much faster than did the total alc. KOH ext. The higher the combined S, the faster was the increase in the oxidation products during a given time of aging. This was also true of a rubber-S-ZnO vulcanizate. The alc. KOH ext. and the oxidation products of rubber-S mixts., 1 of which contained normal rubber and the other of which contained acetone-extd. rubber, were then detd. With the vulcanizates contg. normal rubber the proportion of oxidation products increased slowly with the degree of vulcanization, while with the vulcanizates contg. extd. rubber, it increased rapidly. The acetone ext. (minus free S) remained virtually const. throughout in each case. A large quantity of oxidation products were obtained by alc. KOH extn. of a rubber-S vulcanizate contg. acetone-extd. rubber, and purifying the KOH ext. with water. The mixt. was a brown, opaque mass with little elasticity, and insol. in C_6H_6 , xylene, benzene and Et_2O . Tabulated data give the ash, N, combined S, C and H of the acetone-extd. rubber products from vulcanizates of different degrees of vulcanization, and show that the ash content of the oxidation products originated from the KOH treatment, that the oxidation products contained combined S, and that the products contained 3.7–5.2% O. When the cure was increased from 2 to 6 hrs., the oxidation products increased from 0.4 to 1.4%. In the same way a rubber-S vulcanizate (from acetone-extd. rubber) was analyzed after increasing times. The results are tabulated. After 2 weeks the alc. KOH ext. was no longer completely sol. in Et_2O . Both the Et_2O -sol. and the Et_2O -insol. portions contained combined S in smaller proportion than in the acetone-extd. vulcanizate. The Et_2O -sol. portion increased from 3.4 to 5.3% during the 8 months' aging. The Et_2O -insol. portions had higher O contents than the Et_2O -sol. portions after the same periods of aging. Expressed in terms of H/5C, the ratios of H to C in the acetone-extd. vulcanizates, in the Et_2O -sol. and in the Et_2O -insol. portions of the alc. KOH exts. diminished gradually with the time of aging. This indicates that during oxidation H is oxidized out of the mol., probably as H_2O (cf. Kirchhof, C. A. 7, 4083). In conjunction with the theory of Wieland (*Handbuch der Biochemie des Menschen und der Tiere*, 2nd Ed., 1925, II, 252), it is probable that H_2O is split off and condensation takes place with O as a bridge. Similar tests were also made of vulcanizates (acetone-extd. rubber-S) aged by the Geer oven method. The O contents of the Et_2O -sol. portions of the alc. KOH exts. increased in the same way as in natural aging, but the combined S contents were disproportionately low. Here again the ratios H/5C decreased slowly. The oxidation products were in turn oxidizable, their O content increasing rapidly on exposure to air. Changes in the alc. KOH ext. offer a sensitive method of testing the aging of rubber products, and of formulating specifications for the aging properties of rubber products. This is particularly true when mech. tests cannot be made.

C. C. DAVIS

Rubber manufacture. T. F. H. O'BRIEN. Rubber Research Scheme, Peradeniya. *Trop. Agr. (Ceylon)* 70, 232–9(1928); cf. C. A. 22, 1494.—Complete coagulation was obtained in some trials with Na_2SiF_6 when latex was diluted to 1.5 lb. per gal., but in other tests it was not complete. The coagulum was softer than that produced with $AcOH$. In both lab. and factory tests, entirely satisfactory results at 0.5 the usual cost were obtained with a suspension of 8 parts of Na_2SiF_6 in 1 part of HCO_2H and 1600 parts of H_2O , when the latex was diluted to 2 lbs. per gal. This soln. produced sheets remarkably free from bubbles, but it cannot be used with Al equipment. *p*-Nitrophenol added to the coagulant soln. at the rate of 0.025% by wt. did not affect the rubber in any observable way but largely prevented the development of fungi and molds, even under very adverse conditions.

A. L. MEHRING

Balata in Para. FREDERIC M. BRAGA. *Bol. Agr. Ind. Com.* 2, 428–35(1928).—Climatic conditions in the balata area, various species of *Mimosa*s which yield balata latex, methods of extn. and market conditions are discussed, including data on products and exports. The following % analysis of British Guiana balata (crude and dry, resp.) was made at the Imp. College of Georgetown: moisture 1.9, —; gutta 49.7, 50.7; resins 44.0, 44.8; proteins 3.8, 3.9; ash 0.6, 0.9.

Use of rubber in the chemical industry. J. PANEM. *Rev. gén. caoutchouc* 6, No. 49, 15–7(1929).—An illustrated description of recent development.

C. C. DAVIS

Adsorption and diffusion of gases through rubber and through balloon fabrics. ANDRÉ DUBOSC. *Rev. gén. caoutchouc* 6, No. 49, 14(1924).—A review (cf. C. A. 22, 2078).

C. C. DAVIS

The absorption of oxygen by rubber. G. T. KOHMAN. Bell Telephone Labs, J. Phys. Chemistry 33, 226-43 (1929).—The expts. deal with the absorption of O by raw and vulcanized rubber, and with the relation between the rate of O absorption and natural aging, the ultimate object being the development of an accelerated aging test. The influence of surface area on the rate of O absorption, the rate of O absorption as a function of the state of cure, the influence of the extent of milling on the rate of O absorption, the effect of antioxidants and of ozonized O on the rate of O absorption, the changes in tensile strength which result from the O absorption and the effect of heating in inert gases on tensile strength were studied. The absorption app., which is described and illustrated, allowed the maintenance of a const. temp. and a const. O pressure. With rubber-S vulcanizates in O at 80°, expts. indicated that oxidation by O is autocatalytic and comprises at least 2 reactions, an addn. to the double bonds and a decompn. of the mol., the latter reaction continuing after the first was complete. The proportion of O absorbed was greater than the theoretical quantity to sat. the double bonds. With continuation of the reaction, the rate of absorption of O approached a const. value; water was formed, but almost no CO₂. When 0.02-0.05 mol. of O per C₁₅H₁₆ was absorbed, the vulcanizates became tacky, then weak; when they had absorbed 0.5 mol. of O, they lost their tackiness; with an absorption of 1.0 mol. of O they became hard and brittle. Surface checking was evident in some cases, this phenomenon being regarded as a preferential surface oxidation. At 80° the rate of absorption of O was noticeably influenced by the surface area per unit wt. when the area was small, but when the area was 40 or more sq. cm. per g., small variations in area were without much effect, probably because then the rates of diffusion of O were great enough to keep the rubber satd. with O. Expts. on the influence of the state of cure on the rate and extent of O absorption indicated that there was a close relationship between natural aging and O absorption at 80°, the same reactions probably occurring. The mechanism of O absorption by raw rubber differed from that by cured rubber, curing increasing both the rate and the proportion of O absorbed and changing the character of the absorption curve. The rate of absorption increased with the degree of cure. After curing, the relative rates of absorption of rubber milled to different extents indicated that O was absorbed during the milling process. Antioxidants have a neg. catalytic action rather than preferential absorption. In their presence the rate of absorption was retarded to an extent which varied with the concn. and the character of the antioxidant. In 1 case too small a proportion of an antioxidant hastened oxidation instead of retarding it. The character of the absorption of ozonized O differed considerably from that of pure O, the former being absorbed far more rapidly at first, but the rate diminished so that it ultimately became less than that of pure O. The reaction between rubber and ozonized O was not autocatalytic; the ozonized O apparently protected the rubber from the action of pure O, since the rate of absorption was much less in ozonized O, and on subsequent treatment with pure O the normal rate of absorption with the latter was not reached. Detns. of the relations between the proportion of absorbed O and the tensile strength of vulcanizates showed that as long as well-cured vulcanizates retained sufficient tensile strength to be of practical value, the deterioration was directly proportional to the proportion of O absorbed at 80°. When 0.5% O was absorbed, the tensile strength diminished nearly to 0.5 its original value. When undercured vulcanizates were heated in inert gases (N and CO₂), the tensile strength increased at first, as a result of further curing, but then diminished at a rate which was insignificant compared with that in O. In CO₂ the vulcanizates turned black, suggesting a reaction involving CO₂. The results in general indicate that natural aging is essentially a result of an absorption of atm. O. Forty-two references to closely related work are included.

The standardization of rubber. FERDINAND BRÜCKMANN. Gummi Ztg 52, 1163-6 (1929).—It is proposed to classify raw rubber not primarily according to method of prepn. and superficial appearance but according to its cleanliness. Raw rubber would thus be divided first of all into (1) pure rubber, which is clean enough without washing for any ordinary use, and (2) crude rubber, which is contaminated with dirt sufficiently to necessitate washing. Plantation rubbers fall into each of these classes, depending upon their condition. Within these classes, rubbers are grouped according to whether they are prepd. by artificial or by natural coagulation and then in turn according to their thickness, color, general condition, origin, etc.

Some practical aspects of rubber evaluation. E. P. DIMMORA. Goodyear Tire & Rubber Co. India Rubber World 79, No. 6, 77-8 (1929).—There may be as great variation among individual bales of a lot of rubber or even within a bale as among different lots. As a result, blended batches vary day by day when tested experimentally.

in accelerated mixts., in tread and solid tire stocks, etc.; this variation also holds true under service conditions. Ordinary methods of blending are not effective in minimizing to a satisfactory extent this normal variation, and the only advisable procedure is to mass as much rubber as practicable on mills, to test each batch and to classify the batches as high-, medium- and low-grade. These individual grades are then used in different rubber formulas in which each is most suitable. In testing the batches, modulus tests of formulas, which have been found to be reliable criteria of the behavior in service of the factory stocks concerned, are essential, but short cures at high temps. with cold water conditioning make complete control tests possible in 25 mins., *i. e.*, within practical working limits.

C. C. DAVIS

Rubber as it is revealed by x-rays. G. L. CLARK. Univ. of Illinois. *India Rubber World* 79, 55-9(1929).—C. shows that unstretched rubber gives broad diffraction haloes characteristic of "amorphous" substances, but that stretched rubber gives a diffraction pattern characteristic of cryst. substances. He then tabulates the essential exptl. facts derived from x-ray studies of rubber by Katz, Hauser and Mark, Feuchter, Meyer and Mark, Clark, and others. Natural rubber in practically every state, *e. g.*, coagulated latex, crepe, smoked sheet or vulcanized sheet, produces a cryst. diffraction pattern on stretching, whereas synthetic rubber does not. The initial appearance of a pattern is at about 75% elongation for raw rubber and above 250% for vulcanized rubber. The intensity of the diffraction spots increases linearly with increasing elongation, while the intensity of the broad halo decreases simultaneously. The positions of the interferences are const. with increasing elongation, while their breadths are const. with increasing elongation to at least 800%. The size of colloidal micelles may be calcd. When stretched isothermally, *i. e.*, very slowly, the interferences are very faint or absent, but when stretched adiabatically, *i. e.*, very rapidly, the interferences attain their max. intensity at the same elongation. The pattern appears instantaneously on stretching, and it disappears at about 60°. The pattern disappears on releasing the tension, though sometimes it persists some time after release, especially if the specimen is cooled after stretching. Stretched specimens placed in solvent vapors no longer produce cryst. diffraction patterns. By "racking," rubber can be stretched 10,000%; and it then gives as sharp a diffraction pattern as do pure org. compds.; it is insol. or largely non-swelling in the usual org. solvents. Extd. rubber, free from resins and proteins, gives the pattern on stretching. The positions and appearance of the interferences are independent of the botanical source. "Frozen" rubber gives sharp concentric rings corresponding to the same spacings as the interferences of stretched rubber. These sharp rings are replaced by broad haloes on warming the specimen. Cryst. fillers give characteristic patterns, usually with a random arrangement of the filler crystals, while the usual rubber pattern also appears. Calendering introduces a fibrous structure detected by x-rays even without stretching. Mastication tends to destroy the cryst. orientation even when strongly stretched. Synthetic rubber and rubber-like polymers produce broad "amorphous" haloes; which remain unchanged up to the highest elongations, though some workers have noted slight changes in some of these patterns, especially at low temp. Orientation apparently occurs in 1 or 2, but not in 3 dimensions. Dimensions calcd. from the "amorphous" pattern of unstretched rubber give values of 14.88 (inner ring) and 6.05 A. U., while very pure extd. rubber gives values of 11.15 and 5.97 A. U. The presence of a solvent increases the former to 14.76 A. U. The inner ring is characteristic of polymers. The most accurate values show the unit cell to be rhombic, $a = 12.3$, $b = 8.3$, $c = 8.1$ A. U., contg. 8 C_6H_8 groups. The colloidal micelle seems to have the shape of a long flat bundle, contg. 10,000 to 20,000 unit cells, or 80,000 to 150,000 C_6H_8 groups. C. points out that though the unit cell contains only 8 C_6H_8 groups, this is not a contradiction of the large mol. wt. The unit cell here, as in the polyoxymethylenes (Hengstenberg, *Z. physik. Chem.* 126, 425 (1927)), contains only part of the chem. mol., the long chain mol. extending through many adjacent unit cells. This chain-like mol., bound by primary valences, is estd. to contain 75 to 150 C_6H_8 groups. These results indicate a very long, preformed mol., in which the C_6H_8 "links" lie on screw axes. In a stretched condition these chains lie parallel, giving a cryst. structure. In the unstretched state they coil and lose the parallel arrangement, resulting in "amorphous" x-ray diagrams. Elasticity is due to ethylenic linkages. Vulcanization, in removing double bonds, should ultimately result in hard rubber without elasticity and in an increase in size of the colloidal micelle. Recent work by C. fully verifies this increase in particle size.

G. R. Y.

Rubber structure research and its bearing on the elastic properties of colloids in general. E. A. HAUSER. Metallgesellschaft, A.-G., Frankfurt. *Ind. Eng. Chem.* 21, 249-51(1929).—Recent research on the structure of rubber is discussed from 8 points

of view: (1) the isolation of 2 components, (2) the transformation of 1 component into the other, and (3) interpretations of the structure from x-ray data. It is suggested that all fibrous substances are constituted of main valency chains bundled together by micellar forces to form parcels of parallel chains. The elasticity will depend largely upon the form of the smallest element, whether this is a ring as in cellulose or a straight chain as in rubber, and especially upon the helix angle. The appearance of x-ray fiber diffraction patterns depends upon the condition of these chains, *i. e.*, whether or not they are swollen. Thus, stretched rubber in solvent vapors loosens the pattern. *Celluloid* is analogous to rubber, for when unstretched, it gives an "amorphous" scattering, since the nitrocellulose has been swollen by the camphor. Whenever elastic stretch compensates for plastic internal flow for a sufficient time, and the viscosity of the lower polymerized phase does not prevent orientation (producing an inelastic product as with many resins), a similar x-ray diffraction pattern is obtained. This has been proved for *gelatin*, other *jellies* and *polymerized oils* in still unpublished work. C. C. D.

Report of the raw rubber specifications committee. ENLWOOD B. SPEAR, *et al.* *Ind. Eng. Chem., Anal. Ed.* 1, 55-6(1929).—Comparative tests of 2 different rubber mixts. by 4 industrial labs. and 1 univ. lab. are given to show the wide variations in the results obtained when the same rubber was distributed to the various labs. The 2 series of vulcanizates were prepd. and tested under conditions as nearly identical throughout as possible. C. C. DAVIS

Hard-rubber dust and one of its recent developments: direct grinding of the dust. FRANK, A. BATH. *Caoutchouc & gutta-percha* 25, 14222-4, 14262-3(1928).—Descriptive, with particular reference to the patented process of Rissik-Fraser & Co. C. C. DAVIS

The recovery of volatile solvents by the system of A. Boecler. A. BOECLER. *Bensin Condensation Syst.* Boecler, Malmoe (Sweden). *Rev. gén. caoutchouc* 6, No. 49, 18-20(1929).—An illustrated description (cf. *C. A.* 22, 2493). C. C. DAVIS

Electrical behavior of rubber-sulfur compounds. DONALD W. KITCHIN. *Simplex Wire & Cable Co.*, Boston. *Rubber Age* (N. Y.) 24, 671-2(1929).—The observation of Curtis, McPherson and Scott (cf. *C. A.* 22, 330) that power factor and dielec. const. maxima correspond to simple chem. compds. is without significance, for by changing the test frequency the maxima can be shifted over a wide range of compn. Boggs has suggested that certain rubber-S compds. are dipole mols. and that, though the raw rubber mol. is electrically neutral, formation of an unsymmetrical rubber-S mol. would produce a dipole, while further addn. of S to form a symmetrical mol. would involve loss of dipole properties. With a low proportion of S, probability favors the formation of dipole mols., while increase of S increases the probability of compensation, and the compn. indicated by the proportion of combined S at max. power factor or dielec. const. would not correspond to the mol. of max. dipole moment. With increase of combined S from 0, the power factor and dielec. const. should increase to a maximum, and then diminish. The dipole power loss would arise from a heat loss from motion, but the mols. would be held by elastic forces, so that in a changing field the surrounding medium would undergo rapid stretch and release. In rubber this would cause friction losses evidenced as elec. power losses. Moreover, with increasing S, the rubber becomes more rigid, so even if the no. of dipoles remained const., the motion would change greatly with changing compn. Vulcanized rubber offers, therefore, a more complicated problem than liquids. However, there should be a characteristic frequency for each compn. in the range where dipole mols. exist, and the softer the rubber the higher this frequency. The higher the applied frequency, the lower the S content at which the max. power factor and dielec. const. should occur, which is shown by means of curves to be true. A progressive decrease in the max. dielec. const. with increasing frequencies is explained by the fact that from 0 to 14% S the no. of dipoles increases nearly linearly, and that, though there are more dipoles at 10 than at 6% S, the dielec. const. for 380,000 cycles is greater at 6% S (the stiffness at higher S contents being too great for dipole response). Even a d. c. test probably does not show the compn. at which the max. no. of dipoles are present, for at high S contents the speed of orientation may become so low that the d. c. test does not permit full orientation. Such studies are important because they may aid in explaining the nature of vulcanization. C. C. DAVIS

The production of glossy spread rubber goods by the aid of vulcanization in ultra-violet light. RUDOLF DITMAR. *Kautschuklaboratorium*, Graz. *Gummi-Ztg.* 43, 1172(1929).—The process of Bernstein for curing rubber mixts. at relatively low temps. in ultra-violet light (cf. *German Patent* 262,708, Class 39b, Gr. 3(1912)) must be carried out in an inert gas or *in vacuo* to prevent oxidation by the O_2 . Expts. show, however, that if tetramethylthiuramdisulfide is used as an accelerator to minimize the curing

time and therefore the exposure, and Se red (cf. D., C. A. 23, 1526) as a protective agent, the spread material may be cured in air. Thus, the mixt. rubber 100, S 3.5, tetramethylthiuramdisulfide 2, $\text{ZnSO}_4 \cdot 5\text{NH}_3$ 7, $\text{Na}_2\text{S}_2\text{O}_8$ 2, Se red 1.8, TiO_2 2, is dissolved in C_6H_6 , spread, dried and exposed to ultra-violet light for a few mins.; the rubber is thoroughly cured and acquires a high gloss.

Rubber roadways. T. H. CHAPMAN. Rubber Roadways, Ltd. *Rubber Age* (London) 9, 439-43 (1929).—A review and discussion, dealing with road-surfacing materials in general use, difficulties in new surfaces, a survey of past exptl. roadways and the results, and future prospects.

C. C. DAVIS

Problems of vulcanization. J. DUGUÉ. *Rev. gén. caoutchouc* 6, No. 49, 13 (1929).—A reply to Bary (cf. C. A. 23, 2070). Further comments on the subjects already discussed are added.

C. C. DAVIS

Power factor and dielectric constant in viscous dielectrics (KITCHIN) 4. Rubber-lined metal tube (U. S. pat. 1,708,141) 9. Composition of fiber and thermoplastic rubber derivative (U. S. pat. 1,708,111) 20.

Rubber. ELBERHARD MEYER-BURSCHE. Ger. 471,879, July 6, 1924. Addn. to Ger. 463,290. Artificial objects are prepd. by impregnating tissues, textiles, paper, pasteboard, wood and leather with rubber and esters of tetrahydronaphthols, with or without simultaneous treatment with a volatile solvent. Filling material is subsequently added.

Rubber. THE ANODE RUBBER CO. (England), LTD. Fr. 647,413, Jan. 17, 1928. In the treatment of natural latex to produce rubber objects, an artificial dispersion of rubber is added to the latex before coagulation. The rubber may be mastic or non-mastic or a mixt. of both. The compn. of the dispersion may be modified by adding during the formation of the deposit a dispersion contg. more mastic rubber than the initial dispersion. Cf. C. A. 23, 1777.

Rubber. SOC. ANON. DES CHARBONS ACTIFS. Fr. 647,151, June 1, 1927. Absorbent substances, preferably in a quasi-colloidal state and dried, are used as

Artificial rubber. 28. Artificial rubber is prepd. by polymerizing, alone or

with drying agents,

dimethyl-

polymeriza-

alkali oleate

-70°; they are stirred

in Na isobutyl-naphthalene-

bicarbonate at a moderate temp. Fr.

above hydrocarbons are polymerized by means

without the addn. of inorg. hydroxylic compds. and

Example, isoprene, glycerol and Na are stirred at 60° in

mixture being obtained. The glycerol may be replaced by starch,

isoprenic alc.

Artificial rubber. R. P. DINSMORE (to Goodyear Tire & Rubber Co.). Brit. 7,050, Sept. 13, 1927. In effecting polymerization of rubber-forming hydrocarbons such as isoprene or dimethyl butadiene, the hydrocarbons are treated with an emulsifying agent such as NH_4 oleate or K oleate, and with a protective colloid such as a protein, e. g., casein or egg albumin. A product of improved quality is stated to be obtained, presumably due to the production of an emulsion of the hydrocarbon, the minute globules of which are subsequently polymerized.

Deposition of rubber, etc. THE ANODE RUBBER CO. (England), LTD. Fr. 647,232, Jan. 16, 1928. Layers of org. substances, particularly rubber, obtained by deposition from aq. dispersions, are dried throughout by keeping a higher temp. on the side opposite to that at which moisture is evapd. than on the latter side. Moist air may be circulated on the side at which drying is retarded. If the drying takes place on metallic molds, the molds are heated, if on porous molds, the surrounding air is heated.

Rubber electrodeposition. P. KLEIN (to Anode Rubber Co., Ltd.). Brit. 296,138, March 16, 1927. The uniformity of thickness of the deposits is influenced by screens which may be formed of insulating material such as hard rubber or celluloid or may be conductive to form equi-potential surfaces. If sep. anode and cathode chambers are used, the screens are preferably placed in the cathode chamber. Cf. C. A. 23, 2067.

Preserving rubber. A. M. CLIFFORD (to Goodyear Tire & Rubber Co.). Brit.

296,398, Aug. 31, 1927. There is added to rubber a reaction product of a dia naphthalene deriv., such as the compound β -naphthylamine, by mixing mol. proportions of β -naphthylamine and ethylenediamine with one-half mol. anhyd. CaCl_2 and heating for 5-8 hrs or the reaction product of a naphthol and phenylenediamine.

Preservation of rubber. THE GOODYEAR TIRE & RUBBER CO. FR. 296,398, Nov. 29, 1927. Rubber is preserved by incorporating in the mixt. to be preserved the reaction product of a phenol and an amine. Suitable compds. include (or α)-naphthylamine and diaminodiphenyl- β -naphthylmethane (by reacting β -naphthylamine with CH_2O to form methylene-di- β -naphthol, which is heated to 280° with the presence of CaCl_2). Cf. preceding abstract.

Rubber dispersions. P. KLEIN and A. SZEGVARI (to Anode Rubber Co. Ltd.) BRIT. 296,454, March 4, 1927. Aq. dispersions of substances such as vulcanized rubber, rubber waste, reclaimed rubber, rubber substitute, synthetic rubber or gutta percha, or mixts. of such substances are prepd. by bringing them into a plastic condition by mech. treatment and then successively adding substances which react to form a dispersing substance, such as oleic acid and NH_3 . Volatilizing substances may be added to the plastic material before dispersing.

Apparatus for maintaining rubber dispersions in circulation to keep them in form condition. P. KLEIN, S. GOTLEB, A. SZEGVARI and G. F. WILSON (to Anode Rubber Co. Ltd.) BRIT. 296,454, March 3, 1927.

Compounding "conditioning substances" with rubber dispersions. P. KLEIN and ANDREW SZEGVARI (to Anode Rubber Co., Ltd.) U. S. 1,708,181, April 9, 1928. A rubber dispersion is treated with "conditioning substances" in the form of a solid material, the particles of which consist of a combination of 2 or more different substances, such as S and vulcanized oil.

Uniting different pieces of rubber. P. KLEIN, F. GABOR and A. SZEGVARI (to Anode Rubber Co., Ltd.) BRIT. 297,127, March 16, 1927. Two or more pieces of rubber, such as those for making articles, formed from natural or artificial rubber dispersions by electrical coagulation, pressing, spreading, spraying, or impregnating, are brought into contact with each other, and the union is effected by heating.

Use of rubber. PATENTEN-VERFAHREN FÜR DIE HERSTELLUNG VON GUMMI-ARTIKELN. AKTIESELSKAPET I NORDENSKO TEKNISK-KEMISK FABRIK. SWED. 297,127, March 16, 1927. In joining articles of rubber, the articles are first roughened, treated with a solution of rubber or latex solns. containing a vulcanizing agent, and then the articles are further treated with a solution of rubber or latex solns. containing a vulcanizing agent.

Apparatus for forming articles of rubber. THE GOODYEAR TIRE & RUBBER CO. BRIT. 296,976, Sept. 13, 1927.

Utilizing waste rubber. COMMONWEALTH RUBBER CO. LTD. BRIT. 296,395, Aug. 31, 1927. See FR. 640,000, Aug. 31, 1927.

Grinding fibrous rubber scrap or similar material. THE PHILADELPHIA RUBBER WORKS CO. U. S. 1,708,123, April 9, 1928. The material is ground in a high-speed mill in the presence of steam at such low pressure as to effect partial wetting of the material. An apparatus is described.

Rubber articles. THE ANODE RUBBER CO. (ENGLAND), LTD. FR. 296,398, Nov. 29, 1927. In the production of articles by repeated dipping of a mold into organic solutions, particularly of rubber, the mold is heated between the dippings and, if desired, during dipping. Between the dippings the mold should be kept moist. Means for promoting coagulation, such as gypsum molds or porous molds through which the article is drawn, may be used.

Flower pots, vases, etc., made of rubber. C. PAPWORTH and E. JARVIS. BRIT. 296,583, Oct. 20, 1927. Various structural details as to reinforcing the rubber are described.

Rubber vulcanization accelerators. L. B. SEBRELL (to Goodyear Tire & Rubber Co.) BRIT. 297,051, Sept. 13, 1927. An accelerator is made by reaction of a mercaptobenzothiazole with an aldehyde amine condensation product, e.g., mol. proportions of mercaptobenzothiazole and crotonaldehyde aniline reaction product are mixed and refluxed for 2 hrs. or longer. Other reagents which may be used include: mercaptobenzothiazoles, mercaptomethylthiazoles and reaction products of acetaldehyde and aniline, crotonaldehyde and methylamine, propionaldehyde and methylamine, butyraldehyde and aniline, butyraldehyde and toluidine, heptaldehyde and aniline, heptaldehyde and toluidine, and cinnamic aldehyde and aniline.
